THE AUTOMOBILE

FRENCH RACE HAS ONE-LUNG WINNER

By W. F. Bradley

BOULOGNE-SUR-MER, June 20—The fifth annual voiturette race has proved conclusively that more power, and consequently higher speed, can be obtained from a single cylinder car of 39-10 by 10 inches bore and stroke, than from a four-cylinder of 2½ by 5½ inches. This year's race was specially designed to encourage the construction of small four-cylinder engines, and in the opinion of the one-lunger exponents, the multiple cylinder engines had been given too much liberty. The results of the race proved, however, that even with the increased bore and stroke for the four-cylinder engines they were not equal to the one-lungers. for first prize was won by a single, second by a twin, third and fourth by a single, leaving all places from fifth to ninth for the four-cylinder cars.

Giuppone, an Italian driver handling a French Lion Peugeot car, secured the first prize by covering the 282½ miles of hilly course in 5 hours 56 minutes 29 3-5 seconds, which is at the rate of nearly 48 miles an hour. No records were broken, but this is accounted for by the fact that the course was much more hilly than any one on which previous voiturette races have been run. Twelve rounds had to be made, each giving a series of hills, with grades of respectively 10 and 12 per cent in two cases, with a sharp bend at the base and a length of nearly a mile.

Second prize also went to a Lion Peugeot car, a special two-cylinder model driven by Goux, who came in six minutes behind his team mate. Thomas, the ex-motorcyclist, got third position with a Le Gui car, driven by a single-cylinder De Dion engine having the same dimensions as the winner. Lion Peugeot slipped in again in fourth position, with a one-lunger identical with the winning car, and driven by Boillot.

A fine display was made by the Hispano-Suiza cars, four-cylinder models hailing from Barcelona, which were grouped in fifth, sixth, and seventh positions. They are pleasing looking cars with little of the freak appearance that characterized the four single-cylinder racers, hut they were certainly not as fast as these latter. They were more than equal, however, in individual and team regularity. England, who figured for the first time in a French

Giuppone, the French-Italian, Winning the Fifth Annual Voiturette Cup with Lion Peugeot Car

Weighing In Two-Cylinder Lion Peugeot Which Took Second Place In the French Voiturette Race

voiturette race, took eighth and ninth positions with a couple of Calthorpe four-cylinder cars that were marvels of regularity, but could be left standing by the speedy one-lungers. The only other car to finish the race was a four-cylinder Demeester, the performance of which was not in any way remarkable.

How Race Was Run—Nineteen cars lined up for the start, which by reason of a heavy sea fog had to be postponed for half an hour. At 8 A.M. the weather had cleared sufficiently to allow of a departure being made, and the cannonade of open exhausts began, while the spectators were forcibly reminded that castor oil was the general lubricant for the little racers. France, England, Spain and Belgium were represented. England and Spain had each a team of four cylinder cars, Belgium had a pair of four-cylinder cars, and while France had singles, twins and four-cylinder cars, the singles were in the majority.

Few of the drivers were well known to the public, and there was not, consequently, much enthusiasm as the starts were made, Maurice Fournier, brother of Henry, coming in for a cheer as he went by; the Lion Peugeot team exciting interest by reason of their previous victories, and the Englishmen present supplying the shouting for their Calthorpe cars.

Goux took the Lion Peugeot round the 23½-mile course in 29:28, closely followed by Thomas on the Le Gui, with Giuppone not far behind him and the green-jersied Spaniards also hard on his heels. Maurice Fournier had trouble with his one-lunger Werner almost from the start, and after working on both magneto and carbureter, went out with a broken bearing in the front wheel. Crespelle, driving a single-cylinder car of his own make, discovered that his steering gear was faulty, and in consequence retired so as not to endanger the others. A little later the competitors were further reduced by the overturning of another Crespelle and the burning of a third one. One of the English Calthorpes stripped a gear, the two Belgium Fif cars were not properly tuned up, and the single Renault-Schneider car went out early.

Rather Odd-Looking English Calthorpe with Porter at Wheel

The race was absolutely devoid of exciting moments, though never lacking in interest. When the field was reduced to ten cars it was believed for a time that the four-cylinder Spaniards might give the Frenchmen some trouble, but this fear being removed, the point of interest was which of the Lion Peugeots would get first prize, or whether dare-devil Thomas would manage to dash to the front. Goux, who has been victorious in the two previous voiturette races run in Europe this season, kept the lead for the first five rounds with his two-cylinder Lion-Peugeot. Then Giuppone on the single-cylinder model began to get more speed out of his car, passed his companion, took the lead, and maintained it to the end. Boillot, the driver of the second one-lunger Lion Peugeot, shook off the bad luck which had kept him back at the beginning of the day, and on the ninth round made the record of covering the course in 26:43, equal to a speed of 54 2-10 miles an hour. He had lost too much, however, at the beginning to get near the leader, notwithstanding the fact that during the last four rounds he was the fastest man on the course. Thomas, on the Le Gui, was the most daring, but he also had been kept back at the beginning.

Derny and Four-Cylinder Hispano Suiza—Caillola and Faroux in Rear

How Prizes Were Distributed—The Voiturette cup and the City of Boulogne prize went to Giuppone, and the regularity prize was secured by Lion-Peugeot for first, second, and fourth positions; the special prize for the best four-cylinder performance went to Hispano-Suiza; while the Bennett prize for the car showing the least difference in time round by round was awarded to Burgess, the Calthorpe driver.

Normally the winning engine, a Boudreaux-Vernet design turned at 1,600 revolutions a minute, but could be accelerated to over 2,000 revolutions. The average lineal speed of the piston is 45 feet, rising to as high as 72 feet, when the engine was pushed to its extreme limits. As on all the single-cylinder racers valve area was enormous, the Lion Peugeot having, instead of a single inlet and exhaust, three of each for the one cylinder, the operation being by means of rocker arms. For such high lineal speed lubrication had to be given special attention, the fuel employed being castor oil. This, however, has now replaced all other types of lubricant in French speed tests.

Course Treatment Satisfactory—Instead of tar, the course was treated with calcium chloride, the result being that there was no dust and not a single driver suffered in the least from his eyes. The times of all finishing the race follow:

Giuppone, single-cylinder Lion Peugeot	5:56:29 3-5
Goux, two-cylinder Lion Peugeot	6:20:50 4-5
Thomas, single-cylinder Le Gui	6:14:13 2-5
Boillot, single-cylinder Lion Peugeot	6:20:12
Piliverde, four-cylinder Hispano-Suiza	6:27:25
Zuccarelli, four-cylinder Hispano-Suiza	6:33:55
Derny, four-cylinder Hispano-Suiza	6:34:51
Porter, four-cylinder Calthorpe	7:05:08
Burgess, four-cylinder Calthorpe	7:09:24
Vallee, four-cylinder Demeester	7:27:40

DETROIT READY FOR THE GLIDDEN TOUR FESTIVITIES

DETROIT, June 28—Another week and "Glidden tour days," now a pleasing anticipation, will become a reality. If present indications count for anything, fulfillment will far outstrip anticipation in the matter of enjoyment. Everything is practically in readiness for the coming of the Glidden tourists, the executive body of the A. A. A. and members of the A. L. A. M. and A. M. C. M. A., all of whom, in addition to visiting newspaper men and autoists, will gather here during the days immediately preceding the start of the contest. When it is all over those fortunate enough to be in Detroit at any time during that period will have experienced the strenuous life in a manner that will long be remembered.

That Detroiters are keenly alive to the situation, and appreciate what such gatherings mean to the city, is shown by the ready response to a request for funds. The amount determined upon by the Detroit Auto Dealers' Association as sufficient to keep things moving every minute, during the five days when the visitors will be here, has been exceeded by the contributions received. The hearty co-operation being extended the committee in charge of the affair presages success, and, with ample assistance promised, nothing will be lacking.

As indicating the spirit displayed on every hand, Mayor Breitmeyer's attitude is worthy of note. It was at his suggestion that the city offered an additional trophy for the Glidden tour, a magnificent cup that will go to the winner in the baby tonneau class. A massive gold key is being made to present to Chairman Hower, with the freedom of the city. Mayor Breitmeyer, who is the leading florist of the city, has expressed his desire to have the matter of decorating for the big banquet, the night of July 9, left entirely to him, of itself assurance that the floral end of the spread will be worth while. He has also offered the use of the city hall steps for the band concerts Saturday evening and Monday morning, just prior to the start of the tour. The Maxwell Briscoe band is coming all the way from Tarrytown, N. Y., to give eclat to the occasion. It will also provide music for the boat ride on the big *City of Cleveland* on Sunday, in addition to featuring in the auto parade, which will be *the* event on Saturday.

In order to make this day go down in Detroit's history, Mayor Breitmeyer will request that all business houses and residences along the line followed by the parade be decorated. He has also urged that Detroit automobile manufacturers make Saturday a half holiday, so that their employees may participate in the festivities. Inasmuch as at the present time there are not less than ten thousand of these, it will be seen that large accessions to the turnout will come from this source. Some manufacturers have gone further than this, and will give their employees sufficient time off Monday morning to witness the getaway of the Gliddenites, which will take place from the city hall at 9 o'clock. It is anticipated that others will follow suit, wherever conditions are such as to permit suspension of operations, and that the Glidden tour, in addition to providing plenty of enjoyment for entrants, will prove instructive to local automobile interests. At the same time, nothing will be left undone to demonstrate the important position Detroit holds as the hub of the industry.

Wisconsin Horsemen are Notified of Tour

MILWAUKEE, June 28—Frank P. Hixon, president of the La-Crosse Automobile Club, has mailed a circular letter to the editors of all papers in that section of Wisconsin. He asks them to warn farmers and drivers of horses that on July 15, 100 cars participating in the annual A. A. A. tour for the Glidden trophy will run over the roads from Madison to LaCrosse, and asking that horses unaccustomed to machines be kept off the road, especially at hills and crooked points. The Milwaukee and Madison clubs are making preparations in a like manner. Madison, the State capital, will arrange a brilliant welcome for the tourists.

WRIGHTS ARE BUSY AT FORT MEYER

WASHINGTON, D. C., June 29—Orville and Wilbur Wright have been tuning up their aeroplane at Fort Meyer preparatory to the government tests. This afternoon they had difficulty, which was located in the engine and not in the forward planes, as Wilbur thought. A flight of about 600 yards was accomplished by moonlight, the machine being in the air less than a minute.

The Weighing in of the Cars Was Attended with the Usual Conscientious Formalities

NEWS MADE IN GERMANY

BERLIN, June 20—The Prince Henry tour was participated in by 108 cars out of the 113 entered. This was a decrease compared with last year's 144, although the combined activity of the four big clubs: Imperial, Bavarian, Austrian, and Hungarian, made promise of a far larger list.

The tour led through Prussia to Hungary and Austria, winding up in Munich, 1839 kilometers in all, in six daily stages, from June 10 to 18.

In order to level out the chances of the competitors, a handicap of three debit points was worked out for all drivers who had competed in big international events and had been successful in the principal German tours as well. But this handicap was cleverly evaded in numerous cases by other drivers being nominated, while men like Poege officiated as chauffeurs! At the weighing-in, several cars were refused sanction until several alterations had been made, Poege's Mercedes being among the number. The exhaust was wrongly placed, while in one or two vehicles the exhaust box was entirely missing.

The start for the first stage—Berlin-Breslau—was made June 10, Prince Henry of Prussia and the official cars starting ahead of the ruck. One first speed trial took place on the Guben-Krossen stretch. The best time was achieved by Lochner's Opel with 2:42, or an average speed of 122 kilometers, while the highest number of points went to Wilhelm Opel's car with 6.38 points. Poege's Mercedes was second, 5.95 points.

The 101 vehicles which entered Breslau in the pouring rain were all sent off on the longest run of the tour the day following, to Tatralomnicz and Tatrafüred, 409 kilometers, where the strenuous roads accounted for a severe thinning of the ranks.

The Étappe-Breslau-Tatrafüred run was wound up in pouring rain, but on the next day brilliant sunshine and far better roads favored the competitors on the stretch to Buda Pesth, 312 kilometers, when 97 cars reached the Hungarian capital, and the reception was a brilliant one.

Sunday, June 13, was a rest day which ended with a big banquet for 300 persons, arranged by the Hungarian Automobile Club. Prince Henry made a witty speech and concluded with a toast in Hungarian which brought the entire assembly to its feet.

June 14 the start was only made at 9 A. M. for Vienna, a concession much appreciated after the 5 o'clocks of the preceding days. The run was finished by all the 97 cars, and one or two of the damaged ones of earlier days closed up as well. The reception at Vienna quite equaled that at Buda Pesth as far as official circles go, but the Austrian populace itself was very reserved in its treatment of the tourists.

June 15 was a day of rest, when exchange of compliments took place between the old Emperor and Prince Henry and the German and Austrian military sets. In between the lunches and dinners, the committee dealt with protests.

June 16 witnessed the most beautiful run of the whole event, from Vienna to Salzburg, amid wonderful scenery and on splendid roads. Unfortunately, however, two of the favorites had serious tire trouble on the way, these being Count Kolowrat and Poege. Of the 95 cars started at Vienna, 93 entered Salzburg.

June 17, from Salzburg to Munich, 202 kilometers, was done in the pouring rain. The second speed trial for the Forstenried stretch was included in the final day's itinerary. Luckily the weather cleared up on Bavarian territory, and the test was held amid brilliant sunshine. The best accomplishment was achieved by F. Mouson's Opel, which averaged a speed of 120 kilometers an hour, his time being 2:46 4-5. All the cars, 92 in number, arrived in Munich, where June 18 the tour terminated with a banquet and the distribution of prizes.

The first prize was won by W. Opel, who has the honor of gaining the Prince Henry cup and the beautiful prize of the Imperial Automobile Club; the second award went to Poege, Mercedes; the third to S. Kittsteiner, Opel; the fourth to Forcheimer, Benz; fifth, Sachs, Opel; sixth, L. Opel, Opel; seventh, Count Kolowrat, Laurin.

The full official lists will be published later, but Herr Opel has won the prizes for the speed trials both at Krossen and Forstenried, both of which were closely contested.

MARKS SPOT WHERE BLERIOT BEGAN

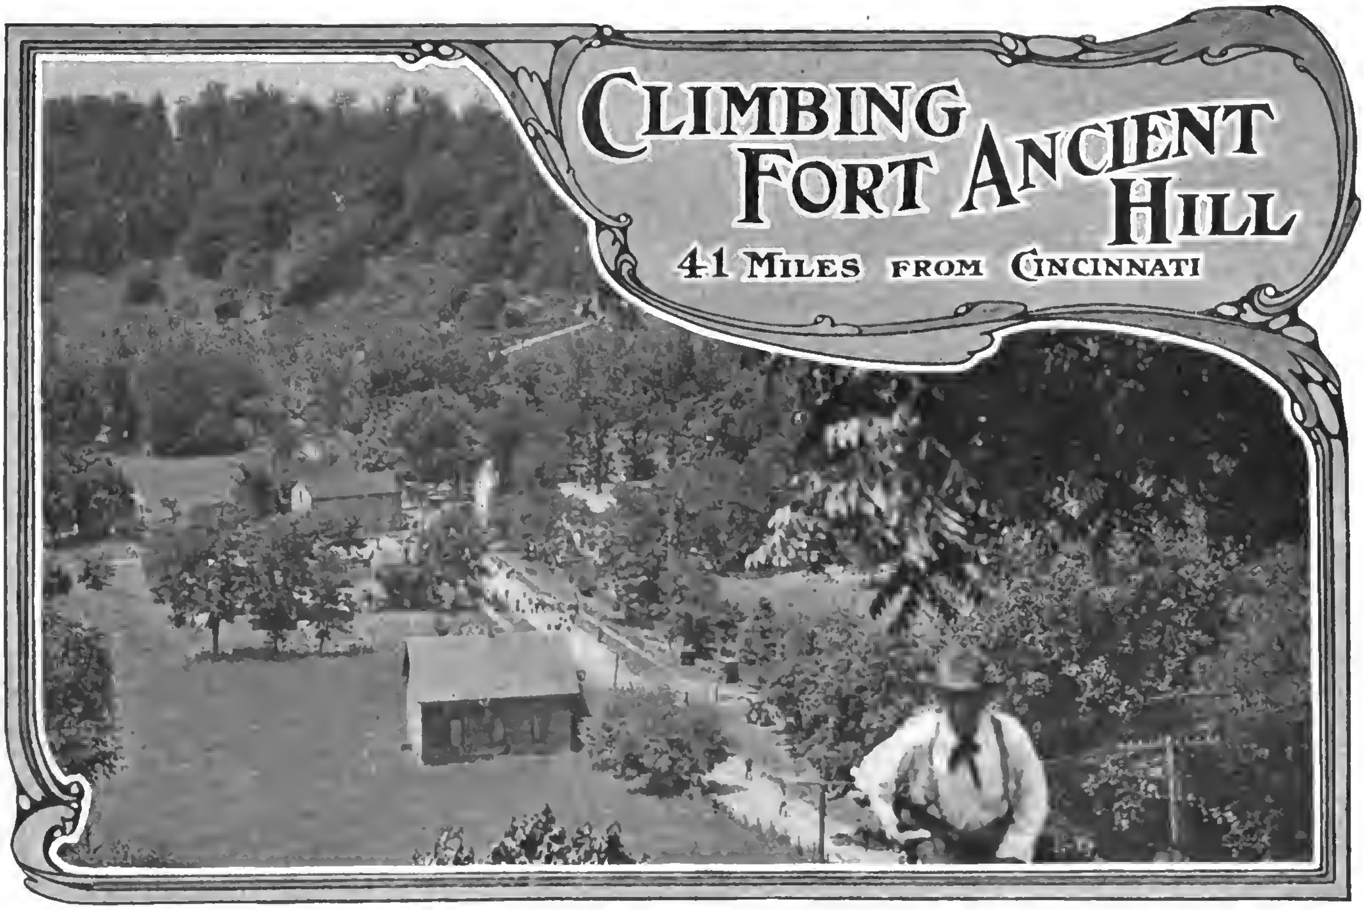
PARIS, June 10—A granite monument, backed by a full-sized model of an aeroplane, now marks the spot where Louis Bleriot left the ground on the first round trip on a flying machine. The little town of Toury being proud of the honor of having been selected as the starting and finishing point of the trip made by the French aeronaut last October, decided on the monument and made its inauguration the occasion of a local fête, where flags and bunting, gendarmes and firemen, local officials and the common people were much in evidence.

In connection with the inauguration of the monument Louis Bleriot attempted to repeat his voyage of a few months ago, but after covering eight miles ran short of gasoline and had to come back to Mother Earth. A second attempt was even less successful, for after flying at low altitudes for a certain distance some of the trip being immediately above the open highway, the aeroplane was seized by a strong gust of wind and thrown into the ditch, where it suffered rather serious injury.

Japanese Aeronautic Progress Kept Secret—That airships are being built in the land of the Rising Sun without letting the world know of the progress in the science on the islands, is the opinion of many persons who recently learned of certain patents placed in that country. Some time ago the commander-in-chief of the army commissioned an officer to investigate aeroplane and dirigible construction with a view to making improvements over the methods empoyed in the late Russo-Japanese war. The result is the taking out of a patent by Yamada on a "safe and free airship." Experiments are to be conducted this summer at a point some distance from Tokio.

Climbing Fort Ancient Hill

41 Miles from Cincinnati



CINCINNATI, June 26—To Cincinnati people, hills "as are hills," to ordinary people seem trivial. And so it happened that the Automobile Club of Cincinnati searched far and wide for a hill to tax autos to the limit, and finally "discovered" Fort Ancient hill. This is forty-one miles from the center of the city, direct east to be exact, and on the line of the C. H. & D. Railway.

The course for real climbing is only two-thirds of the seven-eighths of a mile covered, and therein comes the rub, for cars must be prepared for the two to fifteen per cent. grade, and, so prepared, cannot speed on the one-third of the stretch which is level ground. Prepared for the level, they won't climb; and there you are! In other words, the hill is a "four speed" hill and with two ugly turns or hairpins close together. The hill goes up and up, and steep side hills form beautiful natural grand stands. From the mountain sides the start may be seen down in the valley.

Cincinnati auto enthusiasts, and farmers by the hundreds, turned out to see the climb, and many a private car stuck in the heavy going of the hill, while horses even stopped to rest. But twenty cars were entered, the competition being very keen, however.

Fastest in the climb was the Stoddard-Dayton which had participated on the Saturday previous in the Cobe Cup race at Crown Point, Ind. Driven by Miller, it made the ascent in 1:11 1-5, this being in the $3,000 to $4,000 class. But in the free-for-all the car did not work at its best, the throttle-lever sticking and thus preventing a sufficient supply of gasoline on the level part of the course. Its climb was in 1:32 4-5, some seconds slower than the 1:17 of the Oakland winner, driven by Harry Bauer, a youngster who handled his car exceptionally well. In one event he swung wide on the first turn, almost capsized, and in the coolest manner possible straightened up the car and hit the next curve without hesitation. This happened in the $1,250 to $2,000 class.

The opening event for cars selling for $850 or less went to the Hupmobile, which won twice, being protested on the first trial for not carrying one cushion. The Schacht and Maxwell were other competitors.

William Walker's E-M-F, driven by "Sid" Black, plain and fancy trick rider of bicycle days, and now as fat as an alderman, won the event for stock cars selling for $851 to $1,250.

It was in the event for cars of $1,251 to $2,000 selling price that Harry Bauer took desperate chances and won in grand style over three Buicks.

Two Stoddard-Dayton cars fought it out in the $2,001 to $3,000 class. Carl Wright drove the winner and S. T. Anderson was the loser. Again the Stoddard-Dayton won in the $3,001 to $4,000 class, with Miller up, and in the course record of 1:11 1-5.

It was close in the club members race, for Conkling won in his Stevens-Duryea "Six" in 1:29 2-5 over Pounsford, also with a Stevens "Six," only 2-5 slower. The summary:

STOCK CARS—$850 OR LESS

Pos.	Car	H.P.	Driver	Time
1	Hupmobile	16.9	Gem City Auto Co.	2:22 1-4
2	Schacht	15	Schact Mfg. Co.	2:24 1-5
3	Maxwell	16	J. A. Kilpatrick	2:51 1-5

STOCK CARS—$851 TO $1,250

Pos.	Car	H.P.	Driver	Time
1	E-M-F	30	Sid Black	1:43 1-5
2	Buick	22.5	DeWitt	1:45 2-5

STOCK CARS—$1,251 TO $2,000

Pos.	Car	H.P.	Driver	Time
1	Oakland	40	Harry Bauer	1:22
2	Buick	32.4	O .V. Parrish	1:29 2-5
3	Buick	32.4	DeWitt	1:42 4-5

STOCK CARS—$2,001 TO $3,000

Pos.	Car	H.P.	Driver	Time
1	Stoddard-Dayton	36	Carl Wright	1:19 2-5
2	Stoddard-Dayton	45	S. T. Anderson	1:46

STOCK CARS—$3,001 TO $4,000

Pos.	Car	H.P.	Driver	Time
1	Stoddard-Dayton	45	Miller	1:11 1-5
2	Palmer & Singer	60	Ed. Jungclas	1:31 1-5
3	Stevens-Duryea	44	H. A. Pounsford	1:34
4	Stevens-Duryea	36	E. A. Conkling	1:38 2-5

FOR CLUB MEMBER "OWNERS"

Pos.	Car	H.P.	Driver	Time
1	Stevens-Duryea	36	E. A. Conkling	1:29 2-5
2	Stevens-Duryea	36	H. A. Pounsford	1:29 4-5
3	Stevens-Duryea	54.1	F. H. Miller	1:36 2-5

FREE-FOR-ALL—ALL WEIGHTS AND POWERS

Pos.	Car	H.P.	Driver	Time
1	Oakland	30	Harry Bauer	1:17
2	Stearns	46	A. C. Eggers	1:20 4-5
3	Stoddard-Dayton	45	Miller	1:32 4-5
4	Stevens-Duryea	36	E. A. Conkling	1:33

The Fort Ancient hill will become historic now, for the contest is to be made an annual and at the even mile distance. President Charles L. Bonfield was referee of the contest. Flagmen kept the course very clear and the contests, starting at noon, were over at 3 o'clock.

CHARTER DAY CLIMB IN PLAINFIELD, N. J.

PLAINFIELD, N. J., June 28—Johnston's Drive, beautiful and shady, will be the scene of the Charter Day hill climb, July 6. This is the first contest of its kind near this city, and a course seven-tenths of a mile has been marked out on which six events will be run, four with classifications and two free-for-alls. The entire city and North Plainfield will enter into the celebration, and the Freeholders of Somerset County have granted the necessary permission for the use of the hill and road. Events are open to all comers, according to the entry blanks—amateur and professional, private owners and dealers—and there will be first, second, and third prizes, the first gold medals and the second silver.

Under the sanction and rules of the A. A. A. contest board the classes have been arranged as follows: Cars selling at $1,100 or less, with equipment; cars selling between $1,100 and $1,650; those between $1,650 and $3,000; cars selling for $3,000 and over; free-for-all for runabouts; free-for-all. A special class may be arranged for steamers. Mail entries will close July 5. although it is announced that post entries may be made. The event is under the direction of Alexander Milne, of the newly formed Plainfield Automobile Club, and F. J. Titus, who is acting manager of the climb.

THAT ROADS CONVENTION OF THE A. A. A.

NEW YORK, June 28—Should ample preparation be a qualification, the Second Annual National Good Roads Convention will be a memorable one. Already plans promulgated have been set in motion, and, although the conference does not occur until the latter part of September, those who are connected with its arrangements have commenced their work.

The American Automobile Association and the National Grange join forces in this movement for better highways, and Cleveland will be the scene of their activity in the fall. Secretary Elliott, of the A. A. A., has returned from a trip to see those of Cleveland, Buffalo and Detroit who are interested, at Cleveland meeting George C. Diehl, chairman of the Good Roads Board, as well as the officers of the Cleveland Automobile Club and the Ohio State Automobile Association. The sentiment expressed by the Ohioans was one of genuine enthusiasm, representing that of the manufacturers and owners of that section. The exact date of the convenfion will be announced shortly.

Powell Evans, chairman of the touring board of the A. A. A., has sailed for Europe to represent this country in the annual congress of the Ligue Internationale Association des Touristes. which will be held in London, July 7, 8 and 9. This body includes the largest touring organization in the world, and the A. A. A. has been informed that its application for membership will be acted upon at the coming meeting.

ELECTRIC VEHICLE WILL PAY DIVIDEND

HARTFORD, CONN., June 28—By the order of Judge Cross, of the United States Circuit Court, the receivers of the Electric Vehicle Company will pay all holders of unsecured proven claims a 20 per cent. dividend. They are permitted, also, to pay the same dividend on claims aggregating $101,094.35, which were filed out of time, but must bar all creditors who have not presented their claims heretofore. The petition for the order states that the unsecured claims amount to $2,721,585.76, exclusive of interest, to which must be added the new set. The receivers have $150,000 in cash and the offer of $430,000 for the concern and its assets. It has been decided to sell to the newly-organized Columbia Motor Car Company, and the receivers will make their final report sixty days after July 1.

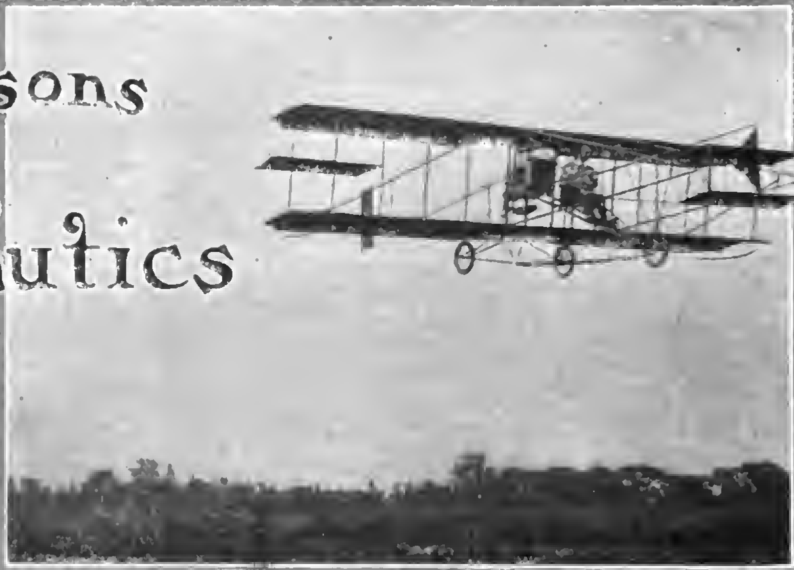
New York Taking Lessons in Aeronautics



Aviator Curtiss Making His Flight That Demonstrated Such Wonderful Control of Machine

NEW YORK, June 26—With a surprisingly perfect flight of one mile, Glenn H. Curtiss, of Hammondsport, N. Y., brought to a close a very successful innings of flying at the old Morris Park race track, located in the Bronx. This was the last event on the program of the Aeronautic Society's first exhibition and contest of all types of aeronautical devices ever held.

In this series of flights, Curtiss has been very successful, and has proven beyond dispute the ability of the machine to fly early, often, and regularly. Beginning with the first attempt the day after the machine had been unpacked and put together, he gave an idea of what might be expected later on, when the machine had been well tuned up, by making an excellent flight of nearly a quarter of a mile. Following this, each successive attempt resulted in an increased length of flight.

In distance alone, this latter was not so very remarkable, but it was the perfect control of the machine by the operator which made it differ from other and longer flights. Rising from a point near the grand stand, Curtiss rose to a height of about 100 feet, and circled around the mile oval as readily as if the machine had been an automobile. At the conclusion of the mile-long excursion, he descended within a few yards of the starting point.

Throughout the circuit of the track, Curtiss rose and fell with ease, whenever an obstacle in the form of a tree made a different elevation either desirable or necessary. Moreover, in turning, the new apparatus was shown to be in keeping with the rest of the machine, in that it obeyed perfectly. Essentially a perfected product, every part of the machine has a finished appearance, in which it differs from the earlier machines constructed by the Wright Brothers. These latter were built with considerable economy, so that many of the parts bore the marks of lack of funds. With the new Curtiss machine, this is not so, and the excellent appearance and correct interrelation of the parts made a very favorable impression, even before the machine had been proven out in actual flight. So excellent was this impression that a local company, which has secured the agency for the Curtiss-Herring machines, was able to dispose of one, within twenty-four hours of taking the agency.

Mechanical Details of Curtiss Flyer—The most successful of the half-dozen aeroplanes with which experiments are now being made is the latest Curtiss machine, as illustrated in the accompanying photographs. This is named Curtiss Aeroplane No. 1, because the first built entirely by Curtiss, at the Hammondsport factory. All previously built machines were the property of the Aerial Experiment Association, including the *June*

Interested Aeronautical Enthusiasts Watching the Experiments at Morris Park Last Week

Bug, Red Wing, White Wing, and *Silver Dart.* The flying machine now at Morris Park track has just been purchased by the Aeronautic Society for experimental work. It is the lightest aeroplane yet built by Curtiss, and in fact is the lightest that has made successful flights, with the exception of the Santos-Dumont monoplane. It made four or five flights of upwards of three-quarters of a mile before it was shipped to New York.

The Curtiss aeroplane is a most interesting and pleasing machine, being well proportioned and showing careful and well-finished workmanship. The woodwork, which is all of Oregon spruce, with the exception of two ash braces extending from the motor to the front wheel and the bamboo poles supporting the front horizontal rudder and the "tail" or combined horizontal plane and vertical rudder at the rear, is neatly shaped, smoothed down and shellacked. The supporting surfaces are made of rubberized silk, the lower planes of light yellow color and the upper surfaces of light chocolate shade. The surfaces are made in sections having metal eyelets pressed into the edge by means of which they are laced to the frame. The combined area of the wheel. It is turned to right or left by the movement of the vertical rudder in the rear, controlled by turning the steering wheel to right or left. Lateral equilibrium is maintained by two movable tips at the extreme ends of the wings, hinged half way between them and projecting half their length beyond the ends of the main planes. These tips are elevated or depressed by the movement of the operator's body against a steel tube shoulder brace plainly seen. The instinctive and subconscious movement of the trunk of the body, away from the side of the machine that begins to drop, causes the tip on that side to present a greater angle to the air, forcing the machine to rise on that side, while a corresponding but reverse movement of the opposite wing occurs, allowing that side to drop. The machine is fitted with a pedal to cut out the ignition and to apply a brake to the front tire. This is useful while landing.

The aeroplane has a speed of thirty-five to forty miles an hour, but must attain a headway of nearly thirty miles before rising from the ground. This is due to its light weight in proportion to the load it must carry. And presenting less surface than the

Martin Glider Which Came to Grief Through the Too Energetic Action of the Auto Which Towed It

supporting surfaces aggregates about 250 square feet, yet it is said that the machine has sufficient lifting power to raise two men from the ground.

Extremely Light Weight a Feature—The total weight, ready to fly, but without the operator, is about 400 pounds, or just about half the weight of the *June Bug* and less than half the weight of the Wright machines. It is driven by a Curtiss aeronautical engine of new design, which is soon to be put on the market. Stripped, the engine weighs only 85 pounds, and with radiator, tanks, etc., the weight is about 150 pounds. It develops from 25 to 30 horsepower. There are four cylinders, copper-jacketed and fitted with mechanical inlet and exhaust valves. The cylinders exhaust directly from ports on the right side into the open air. A Bosch magneto furnishes ignition current, and the water and oil are circulated by geared pumps. Fuel is carried in the cylindrical tank above the engine and lubricating oil in the irregular shaped tank suspended below. A two-blade wooden propeller, 6 feet in diameter and of 5 feet pitch, painted black, is keyed directly upon the end of the crankshaft. Speed of the engine is governed by the throttle.

Over all, the machine measures 29 feet, and it is also 29 feet wide from tip to tip of wings. The biplanes are each 4 feet 6 inches deep and just alike.

There are three means of control of the machine when in the air. It is elevated or lowered by manipulation of a box front control, operated by pushing or pulling on the hand steering

earlier machines, it is to be hoped that it will have to progress at higher speed and prove correspondingly more stable. Moreover, it is probable that this is the best aeroplane in the United States, barring only the Wright machine, than which it is better finished and has a more workmanlike appearance. It remains to be proven more efficient, either in maneuvering or straightaway flight.

Sharing with Curtiss the honors of entertaining the crowd of 10,000 people present, were the glider of W. H. Martin, and the balloon ascensions. Martin comes from Canton, O., where he has made many successful gliding flights, but to-day he did not have the best of luck. Worse than that, he came very close to losing his life. The glider is a monoplane and, lacking a starting means, an automobile was used to tow it. This proved a trifle too speedy, and the bewhiskered operator had a thrilling experience. After the machine had lurched and plunged along for quite a distance, it took a sudden lurch into the race track fence, smashing both fence and glider.

Some excitement was also furnished by the balloon ascension and consequent parachute drops, particularly when the drop made by a woman amounted to about two miles. The dangerous feature of this last drop lay in the fact that the parachute was not properly attached to the balloon, but despite this the woman continued to go up before trying the drop, even after receiving the signal to descend.

An aeroplane built by Frederick Schneider refused to fly, although engine and propellers seemed to be working properly.

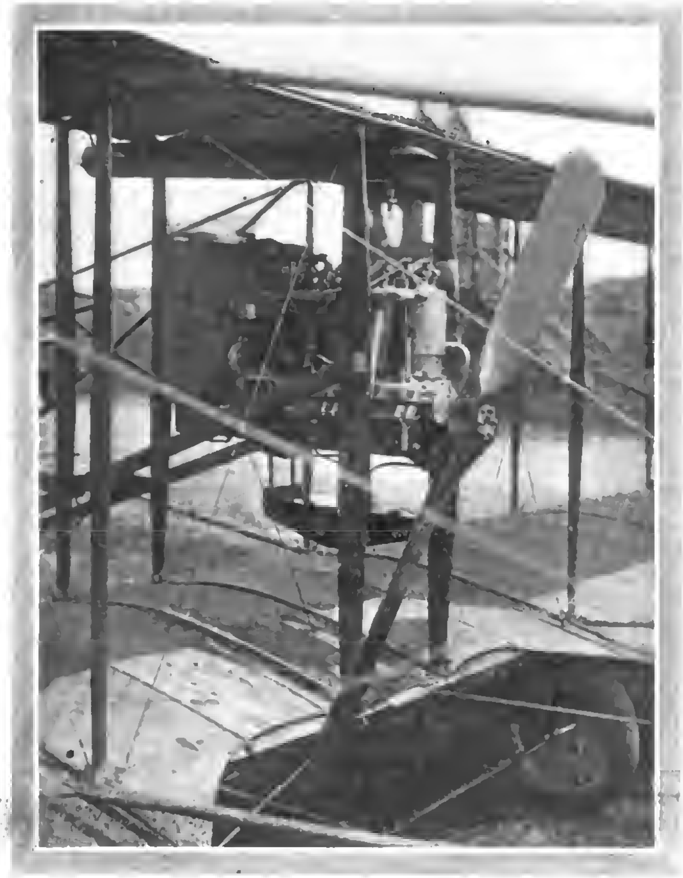
Curtiss Aeroplane at Close Range—A Rear View

FRANCE APPRECIATES AVIATION SUCCESSES

PARIS, June 24—The cause of aviation in France has received a substantial reward by the awarding of the Osiris prize of $20,000 to Gabriel Voisin and Louis Bleriot. The terms of the will of M. Osiris were that the million francs which he bequeathed should be invested and the revenue devoted to recompense the most scientific discovery or reward the most useful work. The selection was to be made by the Institut de France every three years. Only two previous awards have been made, one being to the director of Pasteur's Institute, and the other to M. Sorel, historian and member of the academy.

In the opinion of the Academy of Sciences, which had to report on this subject, the most important work in the year 1908 was the flight of Henry Farman across country on a Voisin biplane, from Bouy to Rheims, and the first round trip across country made by Louis Bleriot, from Toury to Artenay and return. As the two men were once in partnership, it was believed that the letter of the will was being observed by dividing the prize between them, giving $10,000 to Gabriel Voisin, originator and builder of the machine used by Farman, and an equal sum to Louis Bleriot, builder and pilot of the first successful monoplane flying machine.

The prize had to be awarded to Frenchmen, therefore the exploits of the Wright Brothers in France, last year, could not be taken into consideration.



Motor and Propellers of Curtiss' Air Conqueror

METROPOLITAN AGENCY FOR AEROPLANES

NEW YORK CITY, June 25—As indicative of the wonderful strides which the successful navigation of the air has made in the past couple of years, the taking of the local agency for an aeroplane is most significant, for this puts the final OK upon the device. The firm whose products has made this much progress along the line of reliability is the Herring-Curtiss Company, Hammondsport, N. Y., one of whose machines, with Glenn S. Curtiss at the wheel, made such a successful series of flights in this city the past week. The company which has taken on the selling of the Herring-Curtiss machines is Wyckoff, Church & Partridge. An aviation department has been established to take care of this work alone, which will be kept separate from the automobile department.

Not only was the agency secured and plans made to sell a number of the machines, but the first aeroplane was actually disposed of to A. P. Warner, general manager Warner Instrument Company. This sale, too, took place within a few hours of the clinching of the agency agreement. With this sale, attention is called to the facilites of the Curtiss factory for the first time, these being such as to enable delivery within fifty days of the placing of the order. The Wyckoff, Church & Partridge aviation department will be in charge of I. H. Manning, well known in automobile circles in the metropolis.

PROGRESSIVE ST. LOUIS PREPARES AERIALLY

ST. LOUIS, June 28—With the completion this week of the gas mains, the Aero Club will have complete aeronautical grounds, the first built exclusively for this use in the country. From the gas house a 16-in. main is being laid from which a dozen valves will lead for inflation purposes. Besides this, facility for owners of dirigible balloons, provision is made for the accommodation of 10,000 people. The latter includes a large grand stand, under which is space for balloon storage. The club owns two balloons and has three licensed pilots.

The grounds will be ready for use some time in June, and later on, October 9, a series of races for balloons and contests for aeroplanes will be held. For these contests prizes to a value of $4,300 have already been offered, and it is believed that this amount will be doubled before the races come off.

AUTO BUILDER TO ENTER AEROPLANE FIELD

BUFFALO, N. Y., June 28—Like his father, who entered the automobile business early, Edwin L. Thomas intends to be among the first into the airship construction field. With this idea in view, he has formed a company with Carl Dienselbach, of the Aero Club of America, and Dr. Francis Myers, an inventor from Columbus, Ohio. Dr. Myers has invented a machine and is now busy assembling the parts preparatory to a flight. It is expected that the first trial will be held on July 15.

The plans of the company have not been made public, but after the trial, providing that it is successful, aeroplanes will be built in large numbers. It is said that the Myers machine differs from others in kind of engine used, rudder, and size and proportions of the planes. At the test it is proposed to have a number of scientists present so that a successful flight will be appreciated or reasons formulated for an unsuccessful one.

Functions and Frailties of Motor Cylinders

By Thos. J. Fay

CYLINDERS for gasoline motors are made of gray iron castings, excepting in rare instances, as in certain classes of racing cars, when, to reduce weight, increase strength, and guard against rupture, certain grades of steel are used. The history of cylinder work, in all classes of engines, is closely coupled to castings of gray iron, and in view of the ease with which castings of this material may be moulded into intricate shapes, it would seem as if it is the ideal material to employ. There is more to be said about cast iron for cylinder work than the mere statement that, with this material, cylinders are easily made, and that the material is low priced. It is not because the pound price of cast iron is low that it is used; every automobile is in the same category in this regard, thus showing that the cost of the material is no criterion, for if it were, the very high priced examples of automobiles would have better materials for cylinders than will be found in the cheapest cars made.

From the point of view of cylinders, all automobiles are on the same basis, in that all of them use cast iron; this is not to say that every cylinder made is exactly on a par from the quality point of view; there are wide differences in details of design; all castings are not equally made, and the results in practice are not alike. That the cost of the cylinders should interfere as between the several types of cars, is not believed, on the count that inferior cylinder work is even more costly than the other kind, due to the vicissitudes attending the process. The cylinder question partakes of difficulties, not only because "wasters" are a loss, but for the reason that delays are expensive, and the machining work that has to be expended on cylinders before they are "uncovered" sufficiently to judge of their qualities, is at a cost, almost equal to the value of the work required to machine them to completion.

Superior Cylinders Follow Correct Designing—Granting that cast gray iron is a suitable material, it is at once possible to discuss peculiarities of the metal, and by so doing, learn, in what way trouble is likely to follow, and how to avoid it. Fig. 1 depicts sections of cast iron, of various shapes, and section A is circular, of some thickness, resulting in a "pipe," extending down through the core. The pipe does not always extend for the whole length of the core of such a section, but the core material is never so sound as the "skin," or the metal for some depth under the skin. Section B indicates the defective heart of a round section; if a hole is to come in such a way as to drill out the core of the section, the designing question is not so serious and a round section becomes less objectionable.

The rectangular section C performs in quite a different manner, excepting that a "pipe" will appear for a considerable distance down from the topmost part of the casting. Lack of solidity will occur through all the section, in the zones indicated by darkened lines, which occupy portions of the section diagonally disposed, tapering down towards the corners. Section D shows a modified condition that follows the same rules as laid down for section C. Abrupt changes in direction are attended by defects as shown in section E following along the path as depicted in rectangular sections, and the way to avoid this class of defects is to do away with the abrupt changes in direction, and the bunching of metal, in a manner as shown in section F.

Section G represents a modification of rectangular work, and defects are bound to follow for the same reasons. Section H shows how to avoid this class of trouble, and on the whole it is a fair inference that walls should be of a uniform thickness at every point, and fillets should be as little in area as it is possible to have them, without falling into the path of trouble, due to sharp corners. No casting should be so made that the metal will show a positive change in direction at any point; this rule demands that fillets be introduced where sections join, if they are not in the same plane, but, as before stated, it is the aim to have the fillets as light as possible, for the reason that excess metal will result in unsound castings.

Some Normal Features of Design—Following perfectly uniform shapes, in the design, attended by equal thicknesses of walls throughout, excepting at such points where necessity dictates changes, it will be in order to consider one or two such examples: Fig. 2 shows a section of a cylinder, with uniform thickness for the most part; at the bottom, approaching the flange, which is of greater thickness than the walls, the section is thickened up as it approaches the flange, with the result that most of the troubles, due to changes in section, are aborted because the change in section is not abrupt. The "oil-boss," which is shown opposite the piston-pin, on the lower dead center, is of circular section, and the core will be defective, as depicted in section A, Fig. 1, but since the core will be drilled out, as shown in section B, Fig. 1, it follows that the defect will be of no practical significance, provided the boss is as small as it can be in practice. It is of the greatest importance to avoid the use of more material in this boss than necessity dictates, and the old fashioned practice of making the boss very large, in order to have it available, even if it is shifted in the process of moulding, should not be resorted to. In cylinder work, careful moulding is one of the requirements, and the foundryman may not be permitted to do such indifferent work that the bosses will have to be much larger than the actual necessity, merely to compensate for indifferent foundry work.

Sometimes ribs are placed on cylinders, as shown in Fig. 3, the idea being to strengthen the cylinder walls to defeat the tendency of the cylinders to disrupt around the girth near the lugs used for holding purposes. This plan may result in shrink holes in the section of the cylinders, at, or near the inner surfaces of the bore of the cylinders, and the hardness of the metal will vary, due to the opening of the structure approaching the ribs. No cylinder, made with ribs, will have a uniform texture

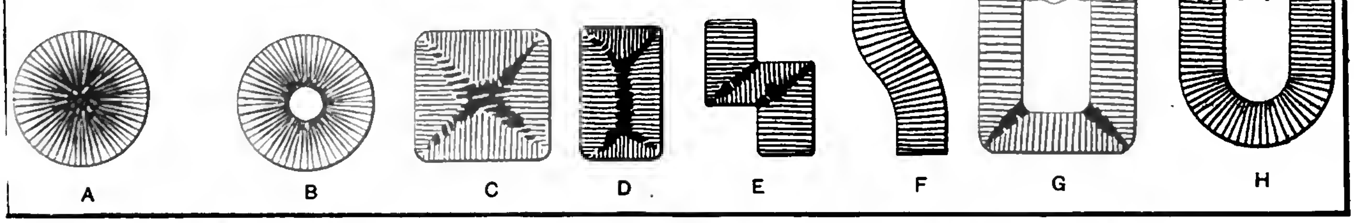


Fig. 1—Characteristic shrink imperfections due to different shapes, and sections, of cast gray iron used for cylinders

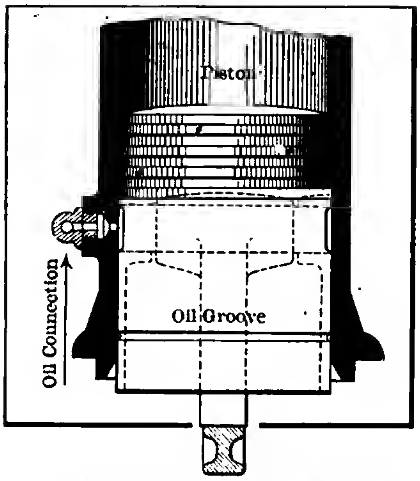

Fig. 2—Section of cylinder showing position of oil boss

throughout, nor is it necessary to risk failure in this way; many examples of cylinders are to be seen at every hand, in which the compression is high; the walls are quite thin, and ribs are absent, and the results, in service, are quite in keeping with the most exacting expectations. Cylinders so made wear evenly, and the compression is not lost, due to scoring, which always follows if the texture of the wall is of varying density, as it is likely to be with ribs or equivalent construction.

Piston rings, since they always press out, against the cylinder wall, with quite a little force, if the rings are tight against compression, will wear evenly if they are given a uniform motion, and if the walls are of equal hardness at all points; this condition does not always obtain in practice, and the rings tend, in consequence, to embed in the metal of the walls at different rates, depending upon the location. At the top of the stroke, for illustration, the rings burrow into the walls, just at the point of reversal of motion, and it has been found that the extent of the damage done will be a minimum if the top ring on the piston is allowed to overlap slightly, as shown in Fig. 4; this is accomplished by recessing the cylinder walls at the top of the stroke, in such a way that the top ring will extend above, for a short distance. This practice is common in steam engineering, but it is not so prevalent in automobile motor work, and it is contended by some designers that it is not necessary to go to so much trouble.

Since piston rings press outward all the time, they are very troublesome when the piston is being inserted into the cylinders; this difficulty is overcome, to a considerable extent, as shown in Fig. 2, by means of a beveled counter bore. As will be observed, it is possible to press the piston up against the bevel, so that the rings will be compressed, but it is not always the case that the bevel is adequate for the purpose. The bevel should be all that the design will afford, without endangering the strength of the cylinders at this point, and it is even a good idea to be a little liberal, in order to be sure that the pistons may be inserted into the cylinders without damaging the rings by pinching them.

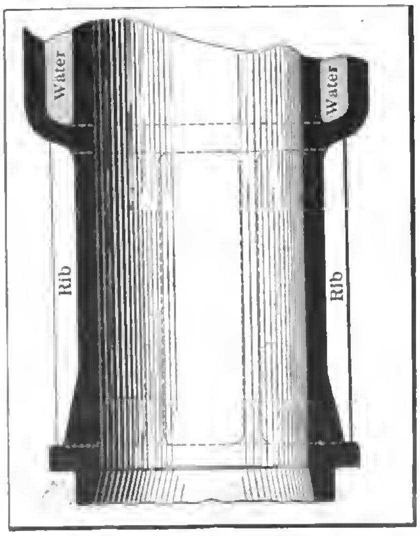

Fig. 3—Section, indicating thickening walls at flange, and ribs disposed around girth

Differences in Expansion Have to Be Considered—The piston should be a free fit in the cylinder, due to effect of heating. and the allowance to be made for differences in expansion will depend upon the design, not only of the cylinder, but the piston, as well, in every case. The piston will expand, due to heat, more than will be the amount of expansion of the cylinder, if the latter is water-cooled; of that there is ample evidence, at every hand. Were the piston designed for water-cooling, and with walls of the same thickness as the walls of the cylinder, in which the piston is intended to reciprocate, the difference in expansion would be limited to such as might be traced to differences in diameters, which would be a negligible quantity under fair conditions.

As it is, pistons are not water-cooled; they are not designed with the same thickness of walls, and they do heat in excess; the result is that they do expand more, and the difference is enough to abort good performance. Since no form of motor will escape the ills of a "neat" fit of the pistons, there is much ground for discussion when the question of the proper clearance is to be settled upon, although some designers claim that a slight clearance is all that the occasion requires. Since pistons do not heat up as much at the bottom, as they do at the head, it follows that the diameter may be slightly conical, and the average fit of such pistons will be superior to the fit in those that are parallel, if they have the same clearance as the maximum that obtains in the cases of the conical types. Noise due to slack pistons is very annoying, and that motors so designed will give very good satisfaction, is not taken for granted; as a rule, this noise is not found in new motors, even when the clearance is more than is looked upon as necessary, and for the most part, it is claimed that this noise comes in when the cylinders are worn to an elliptic approximation, as they will if the pistons are short, and if the compression is high enough to make the pressure very great on one side. When pistons are, in length, about 1½ times the bore of cylinders, they seem to work for a long time without engendering the elliptic formation, and that they should be barely long enough to serve the purpose, is indicated when account is taken of the ills of excess weight of reciprocating parts.

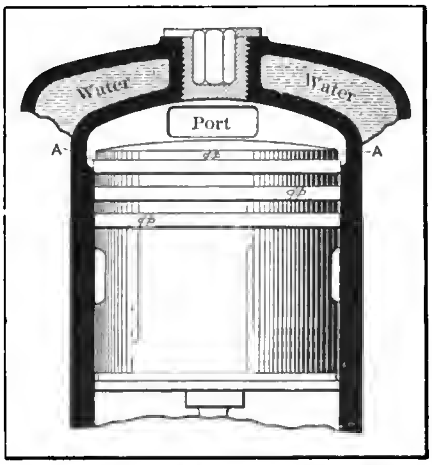

Fig. 4—Section, depicting counter-bore at top of stroke

Approximate Clearance Required—In certain of the motors to be found in cars of some reputation, it is the practice to make the clearance on a basis as follows:

Bore of Cylinder.	Diameter of Piston.
4	3.990
4½	4.485
5	4.980
5½	5.475
6	5.970

In a certain case, in order to be able to fix upon the requisite clearance, pistons and cylinders were heated up to different temperatures, and measurements were then taken, to ascertain the difference between them from the point of view of expansion; it was found that the pistons heated the most, and that the difference in expansion accorded fairly well with the values given above. In these experiments, the cylinders were of the water-cooled type, T design, and the bore was 4½ in. In air-cooled cylinders, of the same size, it was determined that the difference in expansion was less; about two-thirds, in fact, of that which obtained in the water-cooled motors. The cylinders in air-cooled work heat more than in the other class, and the difference in temperature, between pistons and cylinders, is somewhat less; it is a reasonable expectation, under the circumstances, that the difference in expansion will be diminished. It does not, of necessity, follow that the problem, in connection with air cooling, will be any less acute.

(To be continued.)

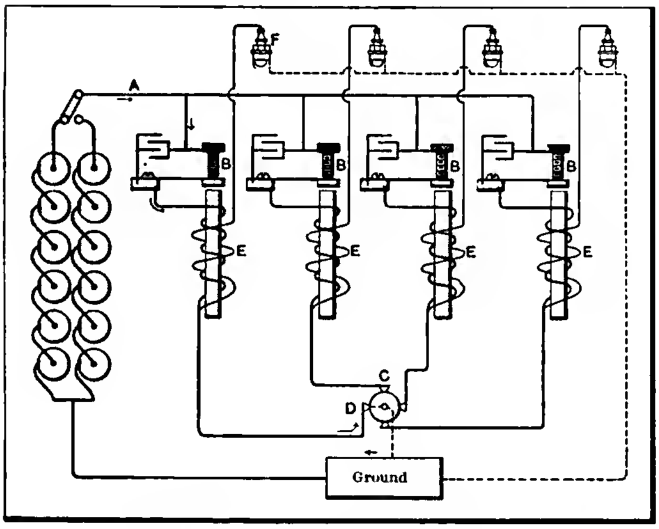
THE DEVELOPMENT OF MAGNETO IGNITION

By H. G. Deupree

PERFECTION of the high-tension magneto has answered a question which assailed the pioneers in the development of the multiple cylinder, changeable speed, internal combustion engine—namely, the production of an efficient ignition system. The high-tension magneto is probably the final word on gasoline engine ignition and has assisted materially in the perfection of the motor, the heart of the car.

It is a comparatively recent product, the result of long years of successful experiment and development by expert mechanical and electrical engineers. This progress may be marked by three successive steps and each period according to the chronological order may be named as follows: The adoption of the battery, the adoption of the low-tension magneto and the universal adoption of the high-tension magneto.

A perfect ignition system is the one which accomplishes the production of a single, hot spark, at either low, average or highest motor speed at the exact instant it is required to effect combustion and under varying conditions as to time; offers a large range for the advance and retard of the spark, a permanent supply of electricity; and withal, is a system of simple construction requiring practically no attention; one free from fine and sensitive parts, which can not be affected by jolts or strains under the stress of strenuous touring or racing conditions; and built with broad margins for the performance of its functions when the carburetor is not properly adjusted, when there is a leakage of compression, or when the spark plugs are fouled and the motor conditions are bad.

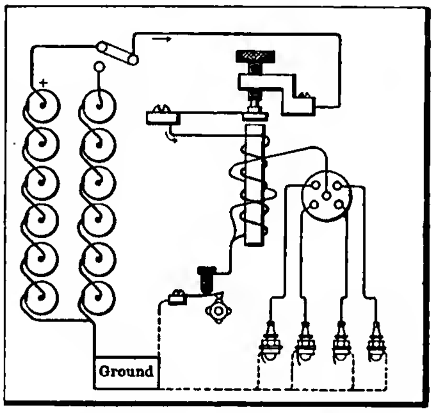


Wiring Diagram Four-Cylinder Engine with Individual Trembler Coils

Perhaps the logical order of discussion of this all important question of ignition is the one taking up the various types of ignition according to the time of their appearance, adoption and recession. This would mean the discussion of first, the battery; secondly, the low-tension magneto, and thirdly, and lastly, the high-tension magneto. The last named should be divided into the leading sub-divisions in which the commercially successsful types of magnetos, as made to-day, are naturally placed according to the principles of construction which differentiate them.

Electric ignition of explosive engines was accomplished on slow speed engines by the use of the primary coil and later by the low-tension magneto. Both of these earlier systems left something to be desired, but the attention of the men working for the development of the motor was first turned to the perfection of the battery. Then came the use of the low-tension magneto, which had worked satisfactorily upon slow speed stationary engines. We will take up the situation at the introduction of the high-speed motor and consider the forms of ignition in use at that time.

Some Earlier Attempts and How They Resulted—The earlier attempts at battery ignition for the motor resulted in the use of dry batteries, a non-vibrator induction coil and a special circuit breaker attached to the crankcase of the engine with a circuit-breaking cam attached to the camshaft. This system was later modified by putting a very high-speed vibrator on the induction coil, as the non-vibrating type drain a battery very quickly. These improvements on the battery were all made on the prevailing theory that a single, powerful hot spark was not as effective nor as sure a system of firing the compressed gas as the shower or series of sparks created by the battery. It was thought that a series of sparks must ultimately produce the explosion, even if the first spark was too weak or if the charge was not of proper mixture or was not sufficiently compressed when the earlier sparks occurred.



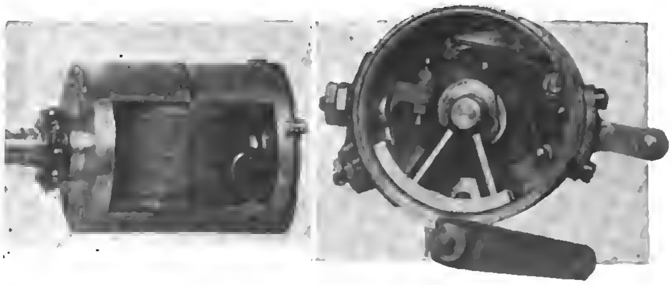
High Tension Wiring with Single Coil 5

It soon became evident, however, that the battery system with vibrators and individual unit trembler coils, or with vibrator and single coil (for jump-spark ignition) could not always be depended upon to fire the cylinders of a multiple cylinder engine with the greatest efficiency. Vibrators are operated by means of magnetic attraction resulting in a mechanical "lag" in breaking the circuit, and consequently the timing of the spark so a discrepancy in the timing occurs such that the cylinder will not fire when the pistons are in the same relative positions.

Any difference in the timing of the explosions results in a very appreciable loss of motor power, since the pistons are not in the proper position when the explosions exert the greatest force, and produce the greatest amount of "torque."

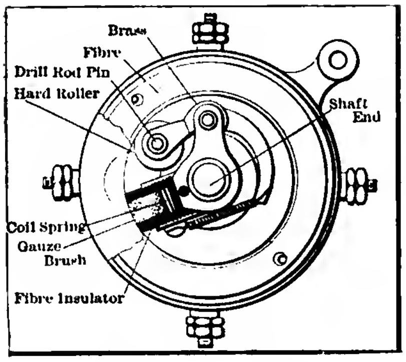
The battery system of ignition may be divided into two general classes. One system employs a commutator or timer and a vibrator coil for each cylinder of the engine. For instance, in a four-cycle, four-cylinder engine there will be one commutator, for vibrators and four spark coils. This system is the most extensively used of the battery ignition systems.

Battery ignition system is one that employs a single vibrator



(a) Primary armature winding (b) Primary circuit breaker

High Tension Magneto Parts Shown in Detail



Common Form of Timer

and single coil, and commutator and multiple distributor, regardless of the number of cylinders. Still another system which may be mentioned is the battery system employing a timing device somewhat similar to that generally found in magnetos. While this has eliminated to some extent the objectionable "lag" of the spark, the device is complicated and retains the disadvantages of the battery systems, such as the ever-present necessity for frequently recharging them.

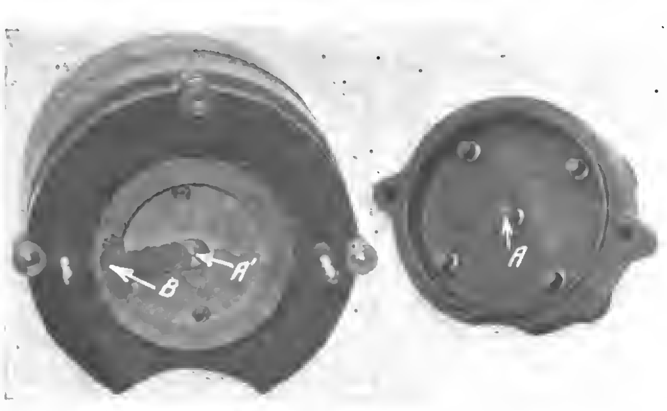
How a Four-Cylinder Timer Works—Take a four-cycle, four-cylinder engine, equipped with battery and four vibrators and four individual unit trembler coils and a commutator or timer. Inside the rim of the commutator are four insulated segments set diametrically opposite. A small bar, driven usually from the cam shaft, and carrying on its outer end a little roller, which also revolves, turns on a pivot in the center of the commutator when the motor is in action. As the metal wheel on this bar comes in contact with the metal segment, imbedded in the hard rubber perimeter of the timer, the electrical circuit is completed. Each segment works with one particular vibrator and coil for the creation of the explosion in a certain cylinder.

The coil referred to consists of a soft iron core, about which is a primary and secondary winding of copper wire. When the electrical circuit is completed through the commutator or timer the iron core becomes magnetized. This magnetized core exerts an influence on the vibrator, causing its armature to vibrate. As the vibrator is pulled toward the magnetized core it breaks the electrical circuit, and it is at this moment, when the circuit is broken, that the spark occurs.

It is well to remember that the spark is caused when the circuit is broken or interrupted. The contact points on each vibrator must be in the best condition, the wiring must be perfect, and the insulation must be in perfect shape—in fact, to get the battery's best efforts everything must be perfect.

Theoretically, the instant the little roller on the end of the bar comes in contact with the segment on the rim of the commutator the circuit is completed, and the core is magnetized, the vibrator is attracted towards the core, the circuit is broken, and the spark occurs. But let the vibrator be put into operation and then the "lag" or variation in the timing happens.

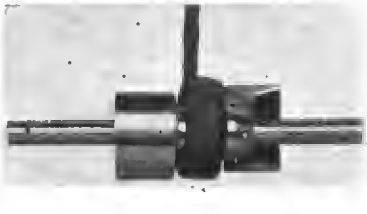
Vibrators Work and Work Continuously—When the engine is running at a reasonable speed the vibrators are in motion continuously. Instead of stopping before they are to be used again they will keep on vibrating and the circuit will be complete when the vibrators are not even in the circuit. The commutator closes with the vibrators in many different positions and



Earlier Form of Moving Contact or Distributor

the spark cannot occur in any one cylinder until the vibrator comes to its position with the circuit closed, the magnetic action of the iron core of the coil attracts it again, opening the circuit, and by this time the spark occurs too late for the best results.

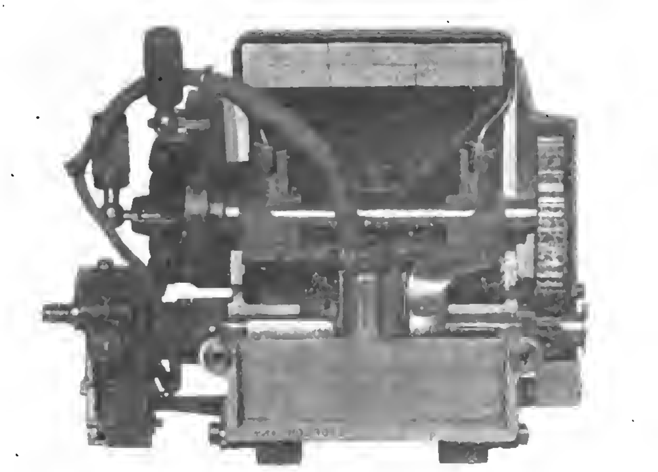
Even when the vibrators are working perfectly therefore, the timing varies an infinitesimal amount of time less than the periodicity of the vibrator. That is the substance of the law deduced from the operation of the vibrator, and it was that small imperfection of the battery system, combined with the expense and trouble of the recharging, which caused engineers to look for a more perfect device.



Inductor Magneto Shaft

The attempt to adopt the low-tension or make-and-break magneto, which had proven satisfactory on low-speed, stationary engines, was the logical step. Faraday had long since discovered that a revolving winding of copper wire in the magnetic field between the pole pieces of "U" magnets would generate an electrical current in that winding or coil.

The low-tension magneto creates a make-and-break, or wipe spark only, as its current is of low voltage and not capable of



Longitudinal Section Through Inductor Type of Magneto

overcoming the resistance furnished by the gap in the spark plug. This is a very simple magneto, however, and easy to manufacture, as it is probably the simplest current generator known. The complication with this system is mechanical, not electrical, and comes in the construction of the make-and-break mechanism, which must be operated mechanically.

This creation of the spark is accomplished by igniters or electrodes which project into the combustion chamber of the engine cylinder. As these points separate the spark is made. These electrodes are naturally very complicated and delicate. They quite frequently wear down rapidly and their presence in the combustion chamber makes it impossible to build the cylinder proof against the leakage of compression.

America Adopted the High-Tension Magneto First—The fact that the Eurpeans first adopted this system and manufactured this low-tension, make-and-break magneto in quantities, gave them a reputation for success in magneto construction which does not belong to them as far as the high-tension magneto is concerned. The high-tension magneto was first an American idea.

As early as 1893 certain American engineers were experimenting and developing a high-tension magneto. It was of the inductor type, however, and when it had been perfected to a point of practical usage on the engine it was found that there was no market for this epochal mechanical ignition system.

Americans mostly were content to see whether success attended the efforts of the Europeans in the development of the self-propelled vehicle, and the few engineers on this side of the Atlantic who brought out motor appliances were forced to wait until the foreigners had proven the automobile a practical working vehicle, designed to revolutionize modern transportation methods.

Distributor for Inductor Type

When success did crown the efforts of the European pioneers in the manufacture of the motor, far-sighted American experts, who were perfecting accessories, had to wait until the Europeans had attained some success in these particular departments before an American market for them was created. Because of this fact the European engineers get credit for a number of important motor improvements which were really produced and perfected on this side of the Atlantic before they even received the attention of the foreigners, who got the credit for all improvements.

So it was with the magneto. It is hardly necessary to discuss the evolution of the high-tension magneto in detail, so this article will deal only with the high-tension magneto as found to-day. High-tension magnetos may be divided into two general classes, the nomenclature in this case being based upon the nativity of their earlier propagators. One may be called the American high-tension and the other the foreign magneto. The American type of high-tension magneto is now used on a majority of cars.

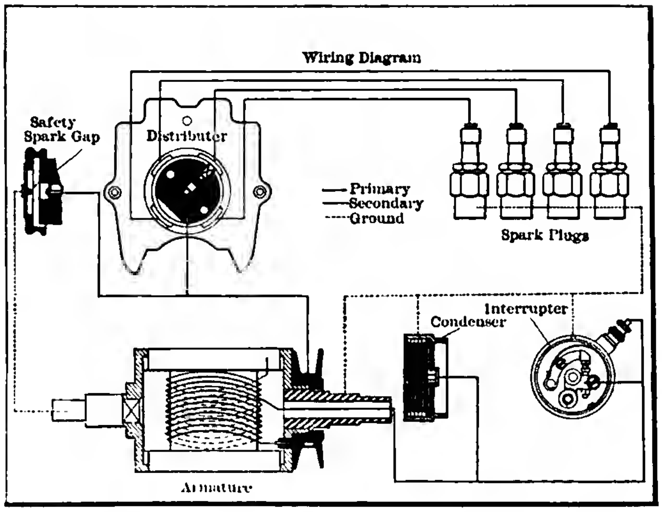
Revolving Winding Marked the Early Types—In the earlier types of magnetos exploited in America the principal of a revolving winding in the magnetic field inducing a current in that winding was retained, but a single breaking device was added to interrupt this primary current and a high-tension current was induced in an induction coil, which was in reality a non-vibrating transformer coil. This system, however, involved the use of carbon or wire brushes, and collector rings to collect the current from the revolving primary winding before it could be taken through the circuit-breaking mechanism.

These moving contacts complicated the construction to a degree past the understanding of the average motorist. However, the use of the induction coil made it possible to insulate properly the wire used and also permitted of a dual ignition on one set of spark plugs, as dry batteries could be wired through the same transformer coil without additional trouble.

In 1907 a new type of magneto was brought out. It was the inductor type, now used so extensively. By revolving a solid steel shaft, on which are two drop-forged steel inductor wings, the magnetic field was reversed twice during each revolution and created two electrical current waves or impulses per revolution. The direction of the flow of magnetism was changed at each impulse, thereby making an alternating current.

By imbedding a circular-shaped stationary winding of magnet wire between the poles of the magnets and around the inductor shaft, it was possible to reverse quickly the magnetism through the winding, consequently generating a powerful current in it. This system made it possible to carry the current directly through the circuit-breaking device by means of heavy lead wires without the use of carbon brushes or collector rings. It also eliminated revolving windings and all moving contacts, and consequently many sources of trouble.

The current is carried to the transformer coil, located on the dash-board, where it is jumped up to the high potential necessary for creating the hot jump spark. From the transformer coil the current is conducted back to a hard rubber distributor on the face of the magneto, and from there is carried to the spark plug. The distributor shaft, which is located immediately above the inductor, revolves a metallic segment past the terminals of the wires leading to the spark plugs. The high-tension current is carried to this segment and transmitted to the spark plug.

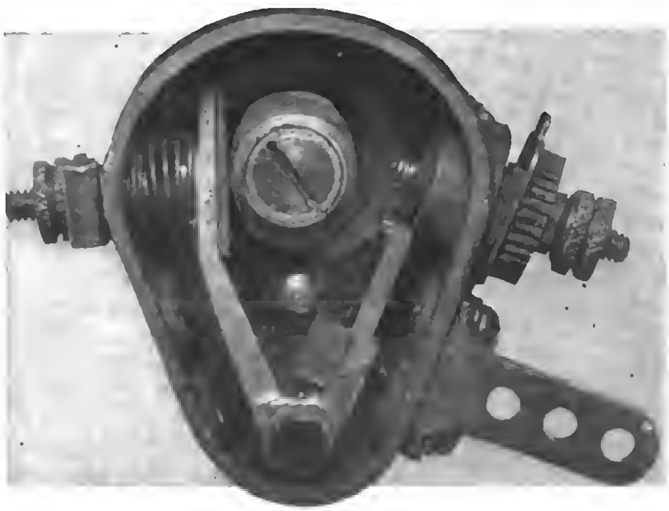


Wiring Diagram Compound-Wound High Tension Magneto

Foreign Practice Differs in the Location of Winding—The European type of magneto has both its primary and secondary windings of wire inside the magneto. The wire varies in length from three to five miles and requires the greatest care in winding to get it into the allotted space. Condensers are also crowded in the space between the pole pieces of the "U" magnets. Brushes are used to transmit the current from the moving windings to the distributor and collector rings.

A magneto of the latest type, and gear-driven, guarantees what may properly be called perfect timing. A hot spark is delivered in the cylinder under compression at the exact instant desired. The inductor type of magneto also offers a reliable system of starting from the seat without cranking. The motor always stops with the magneto in such a position that the first spark will occur in the cylinder under compression. Where batteries are used a push-button is provided and by merely touching it a spark will be made in the cylinder which is under compression.

The battery was improved to its highest point of perfection; the low-tension, make-and-break magneto with its electrodes was then adopted, and then came the high-tension magneto, the crowning effort of expert mechanical and electrical engineers in the effort to produce an ignition system capable of performing its function in a manner to assist most in getting the maximum power out of the motor with the least complication and trouble after the original outlay.



Inductor Magneto Double Cam Circuit-Breaking Device

METHODS OF VALVE GRINDING

By D. R. Hobart

VALVE leakage has its origin in a variety of causes, some of which are due to features of construction, as warping, following the use of inferior material; defective design; lack of even distribution of the cooling medium, and when the water-jacket is shut off for a part of the way around the seat. A second and prolific cause of leakage is due to grinding in the valve, thus reducing the clearance between the valve-stem and the lift; the valve cannot seat after the interference, and it will be necessary to adjust the lift enough to allow the cam to rotate for a complete revolution, without disturbing the valve, on its seat; the usual practice is to allow a clearance between the valve-stem and the lift, the amount of the clearance being a variable, depending upon the diameter of the roller, and the shape of the cam; which clearance will not be the same for the respective designs of motors. Sullage, in the process of casting, is prone to float to the region of the valve-seat, because it is near the top, in vertical casting work, and in this case, the seat is defective, and leakage is a natural sequence; in a case of this sort, it is a new cylinder that will cure the difficulty. Then, there is the question of weak springs to contend with, and in such cases, deposits of carbon are likely to settle on the seat, and prevent the valve from coming down tight; new, strong springs will cure this trouble.

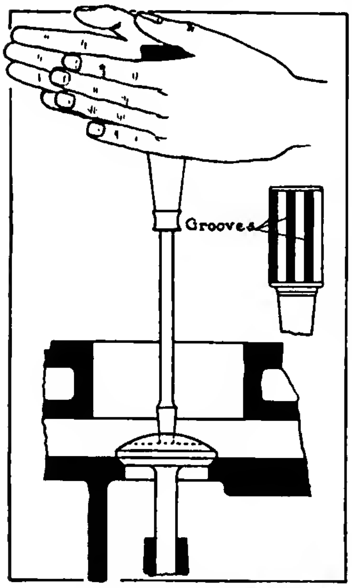


Fig. 1—Method of using screw-driver for grinding valve

Tools Used in Grinding—Shops vary in the tools or apparatus used in valve grinding. Some adhere to the screwdriver, the Swiss file for dressing the faces, and the rose-reamer for truing the valve seat. Others employ special apparatus or drill stocks for the actual grinding and do not true either the seat or the valve face. A third class true the faces in a special tool and either do or do not ream the seats, according to the amount of wear on the latter. It is probable that each shop has excellent reasons for using its own particular apparatus and manner of grinding, from motives of economy of time and labor or by reason of special conditions in the motors. Grinding compounds consisting of two or more grades of emery and rouge paste are universally used, being either made up in the shop or bought ready mixed. The writer inclines to the use of either the screwdriver or grinding machine, truing the valve face in a truing tool and finishing the operation by grinding with emery and oil, using the reamer only when the seat is badly scored or pitted.

Grinding Automatic Valves—Automatic valves and those operating in cages are ground in a similar manner to other valves, and in fact with greater ease, as the valve and its cage can be removed from the motor and the work done in a vise. The test for tightness with gasoline can be better observed, and both seat and face can be examined at any time; whereas, when the seat is part of the motor casting, an electric light is needed for any accurate inspection. It should always be remembered that after a valve has been ground, the stem has to all intent practically elongated, and a readjustment of the spring on an automatic as regards strength and the nut on a mechanical valve for proper clearance will be necessary.

Grinding in with a Screwdriver—Probably the screwdriver is used to a greater extent in valve grinding than either the drill-stock or any one of the excellent grinding apparatus now on the market. The valve is usually given a preliminary examination for scores or deep pits, and if any such are found on the face the latter is dressed with a Swiss file or coarse emery cloth. A handful of waste or a cloth is now put in the valve port to prevent particles of metal or the grinding material from getting into the cylinder, and the valve face coated with a paste of fine emery powder and oil. The valve is now put in place and the blade of the screwdriver inserted in the slot in the head of the valve. The handle of the screwdriver is now held between the palms of the hands, as in the sketch, and a series of oscillations through a small arc given to the valve by moving the palms in opposite directions. After about thirty of these oscillations have been given, the valve is lifted from its seat, given a half turn, and reseated for further grinding in the same manner. This operation should be continued, with occasional additions of oil and emery, until the valve face and the seat appear to be bright for their full width around the circle. Both seat and face should then be washed with gasoline, and care should be taken that no particles of emery are allowed to remain thereon when the valve is put in place. The valve is now seated and tested for tightness by pouring gasoline into the chamber. If there is any leakage past the valve, it should be reground, and again tested until found to be tight. A continuous rotary motion should never be used in grinding, as this will cause the emery to "ball up" and cut a groove in either the valve face or the seat, nullifying the operation and producing a leaky valve. The waste or cloth should be removed from the port as soon as the valve is properly ground, as, should it be allowed to remain, it will be sucked into the cylinder and burned, dirtying the valves, or, if not thoroughly consumed, preventing the exhaust valve from operating. Waste usually contains small bits of metal or emery, and these will score the cylinder or piston, hence the need of removing the waste as soon as the grinding is finished.

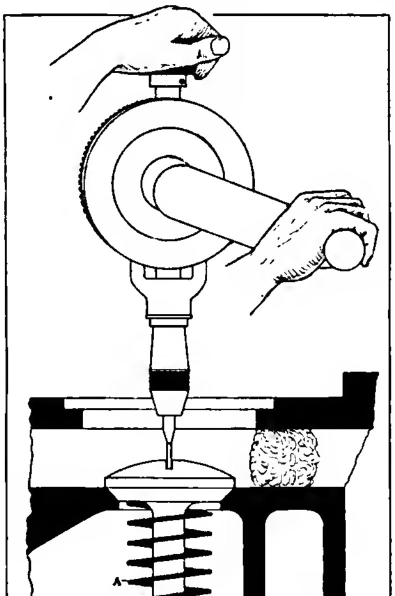

Fig. 2—Grinding with drill stock, showing lifting spring A

Light Pressure to Be Used—For the best results, light pressure should be applied and the operation performed slowly. If the stem is a loose fit in the guide, care must be taken not to allow the valve to wobble on its seat while being ground, or the surfaces produced will be more or less convex, instead of being flat, and will leak. The method of operating the screwdriver has been found to be one in which a light, but firm, pressure can be constantly maintained on the valve without tiring the operator, whereas the usual way, where the handle is held in the palm of the hand and the grinding done by a motion of the wrist, is tiresome and puts too much pressure on the valve. Certain screwdriver handles lend themselves better to grinding than others, an excellent handle being shown in Fig. 1, which illustrates this method of operating the screwdriver. In unseating the valve to give it the half turn, it can be easily lifted by the thumb and finger on the stem below the guide.

Using the Drill-Stock—The drill-stock or rotary drill is employed to a considerable extent where a quantity of grinding is to be done, or where rapidity is desirable. A screwdriver bit is inserted in the chuck and the operation conducted as in the case where a screwdriver is used. Owing to the multiplication between the driving and the driven bevels, the crank should be rocked through a small arc, instead of being rotated. A spring should be fitted within the valve chamber to unseat the valve when it is desired to examine it or when a half turn is to be given the valve on its seat. The spring, which is shown at *A*, Fig. 2, operates as soon as the pressure on the drill stock is released and is of just sufficient strength to overcome the weight of the stock and bit. A plug of waste is shown in position to prevent emery or metal particles from getting into the cylinder.

Valve Grinding Machines—To facilitate the operation of

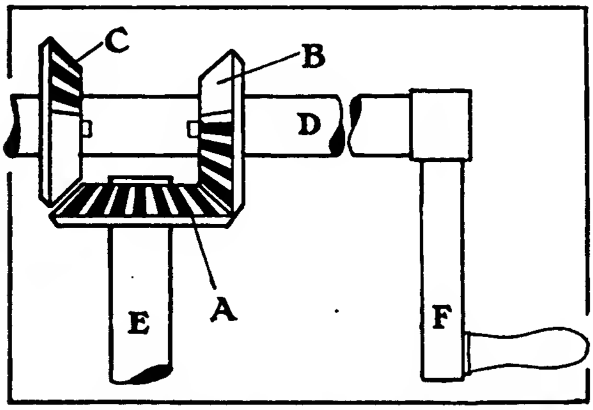

Fig. 3—Mechanism of a typical machine for grinding

grinding, a number of special machines have been brought out to take the place of the screwdriver and drill-stock. For the most part, such machines are constructed to give a limited partial rotation to the valve, whether the handle is rotated or moved to and fro. One well-known model, which is shown diagrammatically in Fig. 3, has three bevels, *A*, *B* and *C*, the first being fastened to a vertical shaft, *E*, to which is attached the screwdriver bit, and the others fastened to a horizontal driving shaft, *D*, operated by a crank *F*. Bevel *A* has its full number of teeth, but *B* and *C* are "mutilated" and are so arranged the teeth of one bevel at a time act on those of bevel *A*. A casing fitted with a handle encloses the mechanism. It will be readily seen that as crank *F* is rotated, a rotating motion, first in one direction and then in the opposite one, is imparted to shaft *E* as the teeth on bevels *C* and *B* come successively into mesh with *A*. Consequently, when grinding a valve, all that is necessary to do is to rotate crank *F* while supporting the machine by the handle, stopping occasionally to allow the unseating spring to lift the valve, and, after giving it a half turn, continuing the rotation.

Where Turning the Valve Is Economical—In cases where a new valve is to be ground in on a well-worn seat or where the valve is heavily scored or carbonized, it will be more economical to turn the face of the valve, either in a lathe or in a special tool, such as is shown in Fig. 4. This tool consists of ing fenders, etc., is illustrated in Fig. 5. A block of steel, *B*, is held against the head of the valve, *V*, and the latter rotated on its seat by means of a screwdriver blade, *S*, inserted in the slot in the stem. The face having been previously trued in a tool like that shown in Fig. 4, it is surprising the short time needed a stock, *H*, to which is attached a head, *J*, and on which are

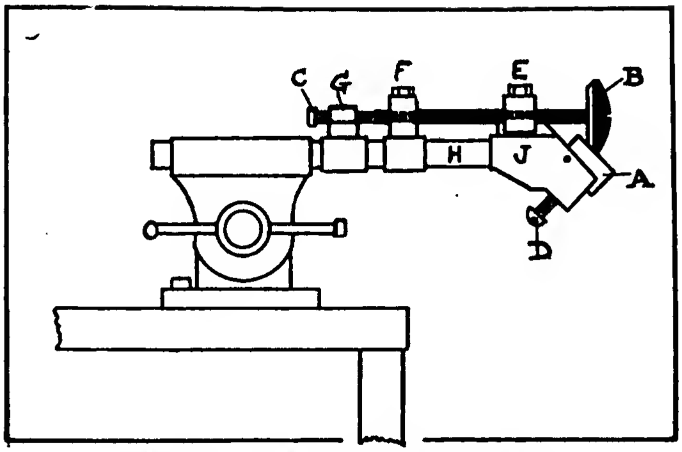

Fig. 4—Valve-truing tool with valve in position

slidable a supporting rest, *F*, and a tail stock, *G*. The head carries a supporting rest, *E*, and a pin on which is pivoted a cutter, *A*, whose angle with regard to the axis of *H* can be varied by means of a screw, *D*. The tail stock carries a screw, *C*, to regulate the depth of cut of the cutter, *A*, when the valve is in place. To true the valve face, cutter *A* is adjusted to the required angle —usually 45 degrees—and the valve put in place, as at *B*. The caps of the rests, *E* and *F*, are screwed down until the valve can be revolved but cannot move sideways nor wobble. Screw *C* is then set up for the required depth of cut and the valve revolved by means of a screwdriver or brace and bit. While this operation sounds complicated, it takes considerably less time than when the valve is ground in on its seat. Any carbon deposit is quickly removed and the face kept true at the same time, whereas, when the Swiss file is used, the result is too often a series of irregular surfaces, which must be trued in grinding on the seat. Having trued the face of the valve, it will take but a short time to grind the seat to correspond. Where the seat is not too badly worn, this preliminary truing of the valve face will often obviate the use of the rose reamer or other seating tool. It will be evident from the above that time is saved over the usual process, in eliminating at least one step therein and in doing away with considerable halts for examination of the work, reapplications of the grinding medium, etc.

A Wrinkle in Grinding Valves on Opposed Motors—The arrangement of opposed motors in the chassis often necessitates the removal of the fenders for ease in grinding with the screwdriver or machine, and considerable time is consumed in what would be done comparatively quickly on a vertical motor. A wrinkle whereby such valves may be ground, without removing fenders, etc., is illustrated in Fig. 5. A block of steel *B* is held against the head of the valve *V* and the latter rotated on its seat by means of a screwdriver blade *S* inserted in the slot in the stem, the face having been previously trued in a truing tool. In cases where the stem of the valve has no slot, a pair of gas pliers can be used to grip it, being careful not to mutilate the threads thereon in so doing.

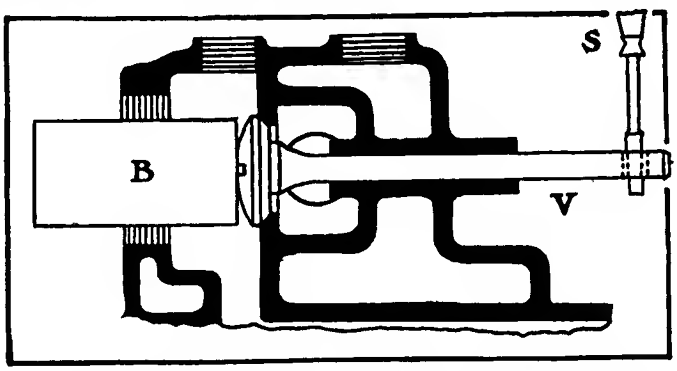

Fig. 5—Block used in grinding valves in horizontal cylinders

LETTERS INTERESTING AND INSTRUCTIVE

PROLIFIC CAUSE OF NOISE

Editor THE AUTOMOBILE:

[1,926]—Will you kindly suggest through "Letters Interesting and Instructive" the cause of and a remedy for a light clanking noise occasionally coming from the left rear axle or emergency brake of a Buick Model 10. The brake spring is sound, nothing is loose, and the manipulation or movement of the car is not affected in the least. Are those bars too long? Or could the differential gearing have anything to do with it?

Welser, Idaho. DON S. NUMBERS.

If your trouble was more fully explained there would be more possibility of our helping you, but "a light clanking noise from the rear axle" is rather indefinite. It is possible that part of your trouble proceeds from lost motion in the parts of the brake other than the spring and lever, of which you speak. Thus the toggle or cam which operates the brakes may be at fault. The fact that this noise is only heard at times and is not continuous, would make a person think that it is something which is only produced under certain conditions, which either throw an unusual strain upon some hitherto unsuspected part or so bring two parts into relations that they mutually interfere with one another.

If the rear axle, itself, were bent or otherwise altered from a perfectly round and true shaft, this resulting condition might cause a noise such as you describe. You have looked up the large things, possibly it would be well to now investigate every little part, no matter how small nor apparently far related. Invariably a source of trouble like this proceeds from the little and unsuspected things.

CHARGING STORAGE BATTERIES

Editor THE AUTOMOBILE:

[1,927]—Having recently removed to a point where it is impossible for me to have my storage batteries recharged, I would like to be informed through "Letters Interesting and Instructive" as to what precautions should be observed in putting the batteries away, out of service for several months, so as to prevent deterioration during that time. Should the batteries be thoroughly discharged and then carefully washed out to remove all of the acid?

W. A. BUTCHART.

Culiacan, Sinaloa, Mexico.

When it is necessary to put away storage batteries, the usual method advocated is to charge the cells fully and then let them stand this way. In your case, however, this is impossible; so the next best way will be to discharge them, remove all electrolyte, and clean out thoroughly. The reason for letting the cells stand fully charged is to gain the added current which results from standing.

This additional current or building up effect was discussed very fully in the issue of May 27, under the title of "Some Further Ignition Hints," by Morris A. Hall.. The title probably led you to think that it was devoted exclusively to ignition, which was anything but the case.

An excellent article on the same general subject appeared in a later issue of THE AUTOMOBILE, that of May 20, headed "Pointers on the Care of Vehicle Batteries." In that you will find the advice given to have cells fully charged before cutting them out.

If you do not desire to waste current from the batteries it would be just as good a scheme in the present case to fill up with pure distilled water to the proper level, and then let the cells stand in some well-covered place, thus partly charged. The cell would thus build up, as in the case of the fully charged ones, although the gain would not be as noticeable in the former case. This method has the additional advantage that when you decide to use the batteries again they will be ready for use, while if they are discharged and cleaned then when you want to use them it will be necessary to carry them to a place where both acid and a charging station are obtainable. As you have stated, this is impossible, so discharging means much future work. In fact, under the circumstances you might just as well "scrap" the batteries as to discharge them.

ON CARBON DEPOSITS

Editor THE AUTOMOBILE:

[1,928]—Will you please give me some idea of the best method of removing carbon deposits from cylinder heads, piston tops and valves? G. J. O'HARA.

Belleville, N. J.

There are two methods, the mechanical and the chemical. The former means taking the engine apart and scraping. The action of chemical decarbonizers is different, and it is said that they act to dissolve the carbon deposits, which are then blown out through the exhaust pipes in the regular action of the motor.

The best method of all is the preventative method. By this is meant the prevention of the formation of carbon within the cylinders. This can be effected by proper care in selecting the oil used for lubricating the cylinders and the method and amount fed in. Also, care must be exercised in the selection and use of the fuel, particularly the latter, as this may, in extreme cases, be such as to deposit particles of carbon in the cylinders. Care in this direction is well invested, however, as any autoist who has ever dismantled his engine for cleaning purposes can testify.

An excellent plan, very much used in England, is brought into use after the engine has been scraped free of carbon deposits. The parts are then coated thoroughly with a very thin coat of liquid paraffin, which can be obtained very cheaply at any store. This is melted and applied to the parts with a brush.

DIFFERENTIAL ELIMINATIO

Editor THE AUTOMOBILE:

[1,929]—I notice that in the June 10 is of "The Automobile" you publish a cut my recently patented compensating gear make favorable comment of the same. T courtesy is appreciated. This late pat was a very slight improvement on my ot patent and the enclosed folder will give a better idea of the working of the proved device, and why it gives a m positive drive than the usual balance g practically eliminating skidding. I across an article in your paper, issue of A 4, 1907, which showed that you underst the deficiencies of the differential and rec nize the need for an improved device for purpose. Should you wish to publish further information about the gear, I send you a working model in wood wh clearly shows the principle.

Boulder, Col. EDWIN J. GOULD

Not only was this substitute for the c ferential shown and commented upon, others which appeared to possess merit w also shown and commented upon. Th in the description of the Ampere car, A 29 issue of THE AUTOMOBILE, pages 703-7 a device for eliminating this troubleso part was called to the attention of th interested. That they were many was sho by the fact that they came back for m information, as per the Letters in May 27 issue, page 865, and June 3 iss page 906.

The article in the April 4, 1907, iss to which Mr. Gould refers, seems to s up the situation with reference to the ba troubles of the differential so well that are reproducing it herewith, completely. was in answer to a letter, and follows:

The fundamental fault with the bala gear, which is the type of differential u on practically all modern cars, is that it d ferentiates for resistances instead of distances, whereas an ideal mechanism its place would differentiate solely for d tance. The effort to drive both wheels, ho ever, while at the same time permitting to rotate faster than the other, inevita involves the trouble referred to. Con quently, only when the difference in resi ance is proportional to the difference in d tance can the differentiating be corre Fortunately, this is the usual case wh both driving wheels are on road surface uniform character, but if one strikes a sl pery spot, while the other is on a dry o the latter may constitute a non-rotating p otal point from which a doubly rapid forw rotation of the other may be executed. In a less extreme case, the wheel on t drier surface may continue to rotate, but a rate much slower than that of the wh on the slippery surface. In either case, serious skid may be produced. Moreover, turning a curve, the action is not to ap the power equally through both wheels un any circumstances. Either one or both the wheels must slip on the road surface a degree sufficient to equalize their spee or more power must be applied through t outer wheel, because its rate of rotation b comes greater while the tractive stress i parted through it remains the same. growing realization of these deficiencies the balance gear seems to be bringing number of leading European engineers the belief that it can be discarded with a vantage in favor of ratchet and clutch d vices. With a ratchet, for instance, t equalizing for varying distance always is p fect, but the drive is definitely appli through the inner wheel on curves. A that this may not be as bad as it appears suggested in the fact that ordinary runni is straight ahead, while curves, when e countered, are in one direction as often they are in the other. In making one co plete turn, no matter of what size, the c cumference of the circle traversed by t outer wheel always is greater than the cir traversed by the inner wheel by an amount equal to double the tread, multiplied by 3.1416. This, in the case of a 56-inch tread, is about thirty feet further for the outer wheel to travel. In the case of a car without differential or any equivalent, this means (if the slip be divided equally) that each rear wheel (if thirty-six inches in diameter) must slip one and one-half revolutions in making a complete circle, three-eighths of a revolution in making the more usual quarter turn, and so on. A further advantage of the ratchet is that it permits use of an undivided rear axle or countershaft. The elimination of all differentiating means gives, of course, a still more substantial rotating construction, which is in a degree retained if a clutch in each hub is used, sufficiently tight to drive ordinarily, yet sufficiently loose to slip before the resistance rises high enough to abrade the tire seriously.

UNIVERSAL JOINTS

Editor THE AUTOMOBILE:

[1,930]—I desire to call your attention to an error which you made in your answer, printed in "The Automobile" of June 17, to letter No. 1915, on the subject of the varying angular velocity in the Universal Joint, in which you misquote from an article by me on this subject, to the effect that changing the relative angular positon of a pair of universal joints 90 degrees does not affect the angular velocity ratio of the driving and driven members.

That part of the original text which relates to this phase of the subject reads as follows: "The conditions, however, which must be met in order to give this result (i. e. a constant angular velocity ratio between driving and driven shafts) are: that the fork axes of the intermediate shaft B, must lie in the same plane, and that the angle between both extreme shafts and the intermediate shaft shall be the same."

In your answer to your correspondent you have entirely disregarded the first condition, namely, that the axes of the forks on the intermediate shaft must lie in the same plane, which is really the most important condition, since a misplacement of these parts to an amount of 90 degrees would not only destroy the equalizing effect of the two joints, but would add the variation of one joint to that of the other, making the total angular variation twice that due to a single joint.

It is to be regretted that some constructions permit of this error in assembling, and although it is doubtful if the effect would be apparent in an actual surging of the car, it would probably develop pounding or rattle in the propeller shaft and increase the rate of wear in these parts.

Bridgeport, Conn. H. VANDERBEEK.

It is to be regretted that an engineer, accustomed to be thorough in everything, is not so in his reading. So, it is that the above criticism is not only ill-founded but actually incorrect, for the letter stated just what Mr. Vanderbeek says it did not state. More than this, the figures given therewith showed just exactly the point, so that, even if the statement had been omitted, the inference would have been the same. But the statement as to the plane of the axes was actually made, as anyone may find by re-reading the letter in question. The first four lines below the second cut, in part, read as follows: "The point not brought out above but assumed is that the three shafts are in the *same vertical plane*. If this is not true, *none* of the above *holds good*."

If our correspondent meant that the vertical axis of his slip joint was turned into a horizontal plane, while the universal joint axis was left in the vertical plane, it is true that, as Mr. Vanderbeek has brought out in his letter, the variations of the two joints will not only not equalize, but will be added, thus doubling the effect, and producing the surging to which our correspondent refers. It was not our understanding that this was meant.

MORE UNIVERSAL JOINTS

Editor THE AUTOMOBILE:

[1,931]—Referring to letter 1916 in the June 17 issue of "The Automobile," are you quite correct in your reply?

If B. S. H.'s car has two universal joints and if they are properly set, would not one of them correct the errors of the other, while, if, as he says, in reassembling he gave the slip joint a quarter turn, then if the slip joint is between the two universals, would not the second universal simply double the errors of the first and give him the surging effect he speaks of? I think so.

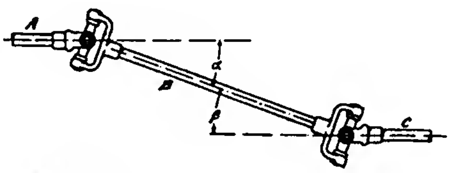
Should not the two joints be like this—as shown in your diagram and not like this—which would be the position were one of them given a quarter turn relative to the other? SIX CYLINDER SAL.

Brooklyn, N. Y.

The figures sent in with this letter were so poor that they could not be reproduced, and the idea intended was not clear, so the original diagram is reproduced with a top view to aid in making it clear. These two figures are intended to bring out the idea of the axes-in-one-plane, which seems to have been misunderstood.

As to the letter above, it appears as if the writer has also misunderstood the original letter of B. S. H. As we have read it and re-read it, there is nothing in it

Top View of Universal Joint



Arrangement of Two Universal Joints

about two universals and a slip joint, or three in all. The writer spoke of but two joints, one of which acted as a slip joint, in addition to being a full universal.

In both of the questions asked, however, the writer has the right idea. The placing of one joint with the plane of its axis at 90 degrees to the plane of the axis of the other joint would result in doubling the errors and giving the noticed surging effect. As to Sal's diagrams, we think they were right, but, as remarked before, they were so poor that it was hard to be sure of the exact idea. The part in which "she" says that the two joints should be as shown in our diagram, reproduced on this page, is certainly correct.

ACTUAL HORSEPOWER

Editor THE AUTOMOBILE:

[1,932]—Will you please publish in "Letters Interesting and Instructive" how the actual horsepower of a motor car engine can be determined when you have given the bore, stroke and number of revolutions per minute. F. M. D.

Anderson, Ind.

There is but one way in which the actual horsepower of an engine can be determined, and that is by testing it. In this test it will be necessary to measure the pull of the motor in pounds at a measured radius of brake arm. This brake arm measured in feet, when multiplied by 2π, will give the circumference of an imaginary circle in which the motor is exerting the force measured. This force is exerted each revolution, so to reduce it to force per minute you must multiply by the number of revolutions per minute. Feet circumference times pounds exerted per minute will give foot pounds per minute. As one horsepower is defined as the power which will do work equal to 33,000 foot pounds per minute, the above result must be divided by 33,000. This will give the horsepower of the engine at the speed measured.

To test your engine accurately, the best way is to measure the power successively from the lowest to the highest speed possible, in intervals of say 100 revolutions. That is, measure the power output at 300, 400, 500, and so on up to 1,500 or whatever is the maximum speed of your engine. Taking these results, the power curve of the engine may be plotted, and from it, the power, at any speed read off.

As this process of measuring power is rather a lengthy one for the amateur owner, and somewhat expensive as well, it is advisable to have it done at some place where testing facilities are available. Thus, nearly all universities and most colleges are in a position to do this testing for you more readily than you could do it yourself. In your particular case, the distance to Lafayette, Ind., is not great, and at Purdue University you can have your engine tested.

ON WIRE WHEELS

Editor THE AUTOMOBILE:

[1,933]—We have read with much satisfaction your editorial note in issue of June 17 on the interesting subject of wire wheels. It is really hard to explain why the public will take such slight heed when approached on the subject of wire wheel equipment. We have regularly listed one of our models this season with wire wheels, and as any opportunity presents itself we try to explain their advantages—but to scarcely any purpose, as with but eight or ten exceptions our purchasers of this model have all insisted on artillery wheel equipment. Not only is the wire wheel stronger under all conditions, and a tire saver because of its resiliency, but it adds fully 25 per cent. to the riding qualities of the car. The writer recently made a trip of 220 miles in one of our "Featherweight Flyer" models, equipped with wire wheels, and a few days later went over practically the same ground with one of these models equipped with artillery wheels, and the difference in the riding of the two cars was simply astonishing. The wire wheel is considerably more expensive to build, but if the public would only accept them we would so equip every car turned out, as the saving to the user on tires and on all parts of the mechanism of the car equipped with wire wheels would be hard to estimate fully.

The writer calls to mind an occurrence in the early days of the industry which demonstrated the effect on tires most conclusively. (I may be wrong as to absolute dates and figures, but the substance is correct.) About 1902 the Oldsmobile Company, in response to public demand, changed over from wire to artillery wheels on their small curved dash runabouts. As I remember, they were using a 28x2 1-2 single tube tire. These tires gave good satisfaction on the wire wheels, but when placed on artillery wheels I know of cases where they absolutely went to pieces in six or eight weeks' time, and the company was obliged to increase the tire size in order to give any kind of satisfactory service. We are using every endeavor to induce our customers to specify them, and firmly believe that they will again come into general use within the next two years.

CAMERON CAR COMPANY.

Beverly, Mass. H. W. DOHERTY.

Where Taft will Summer

By W. H. Doherty

At Beverly Mass.

BEVERLY, MASS., June 28—The summer home of President Taft is located eighteen miles east of Boston on the famous "North Shore" of Massachusetts, in Beverly, which is one of the most beautiful of the smaller New England cities. Mr. Taft, who enjoys keenly automobiling, could not have picked out a more propitious location. The "North Shore Drive," extending easterly from Beverly through Manchester-by-the-Sea, Magnolia, and old Gloucester to Cape Ann; and in the other direction through Salem, Swampscott, and Lynn, where it joins Boston's wonderful park system, is almost beyond description. Miles of its course are bordered with grand old woodland and other miles follow closely the shore of Massachusetts bay. This great highway is the nucleus of scores of others which extend inland for miles and miles, all of finest macadam, over a wonderful rolling country, dotted with beautiful lakes, through quaint villages replete with Revolutionary history; everywhere an atmosphere of calm tranquil existence, where a car glides along, twisting, turning, up and down, over hill and dale with seldom more than a half mile straightaway. Those who have never toured in Eastern New England have something in store for them that they could well afford to drive clear across the continent to find out about.

The President can leave his home in Beverly and drive to the White Mountains over roads which would make even a Frenchman gaze in open-eyed amazement; or he can skirt the shore from Salisbury Beach, across the southeastern corner of New Hampshire, and go on into Maine within a stone's throw of the Atlantic for almost the entire distance. The diversity of scenery to be found everywhere within a radius of 100 to 150 miles in all directions from Beverly cannot be equaled in the United States, combined with such perfect conditions for automobiling. The Massachusetts Highway Commission protects the user of the roads, for on all of the principal highways signs appear at sharp corners or intersections of important roads, and also many other notices of a similar character to acquaint the autoist with what kind of a road is ahead of him.

What a country this would be if these conditions existed in every State! May we hope that Mr. Taft, who has been in every State in the Union and almost every country on earth, will be so impressed with the highways of Massachusetts, and the general development which good roads carry with them, that he will lend noticeable assistance to the efforts which are being put forth all over the country to improve the conditions of the highways! Perhaps we can look forward to some great national highways in the near future. Surely we can if our President can become sufficiently interested, and his sojourn in this section for the four Summers of his term should keep this subject in his mind with a little energy put forth directly to him by those who are actively associated with the movement for national highways.

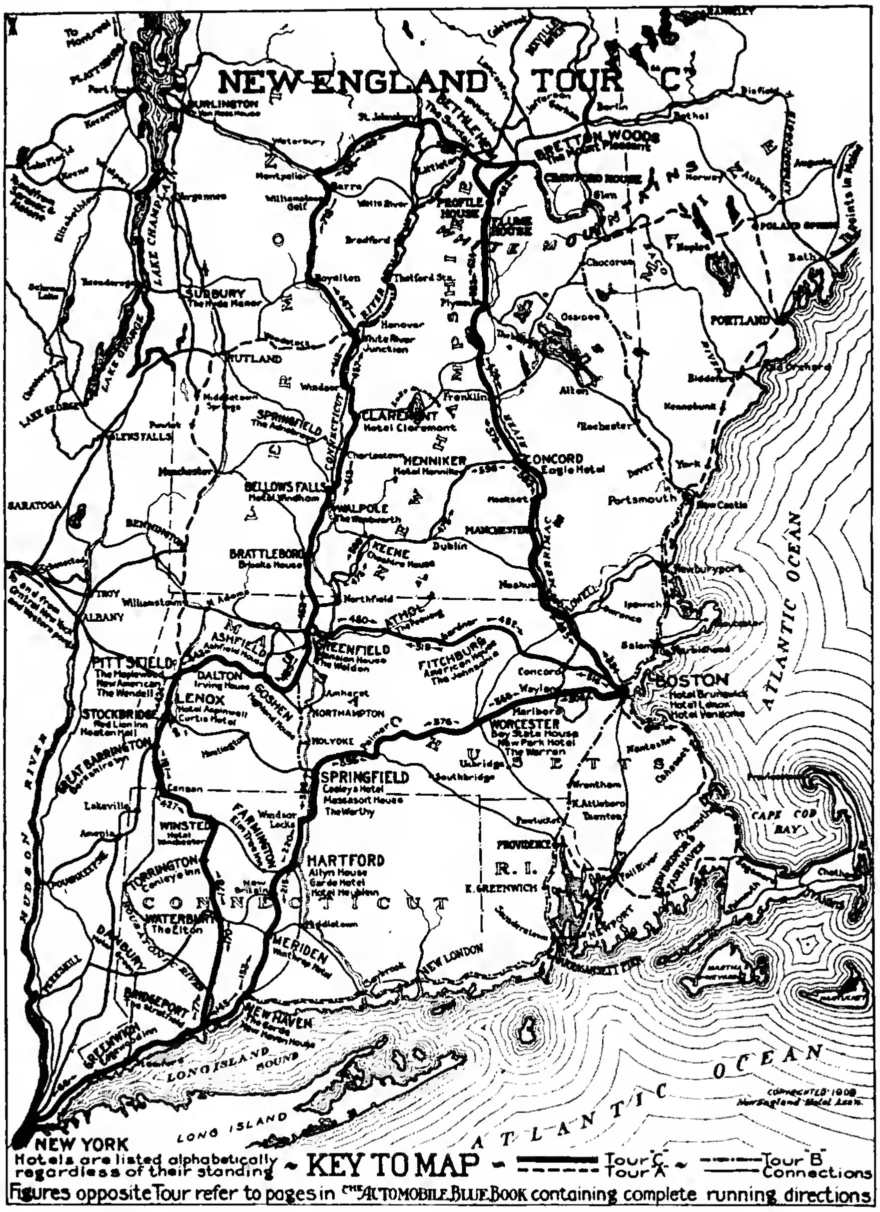
TAFT ENTERTAINS ATLANTA PATHFINDERS

WASHINGTON, June 25—The White steamer and Oldsmobile cars, representing the New York *Herald* and the Atlanta *Journal*, which are blazing a route for the proposed endurance contest from New York to Atlanta next Fall, arrived in Washington on Wednesday and met with a most cordial reception. Several cars went down into Virginia to meet and escort them into the national capital. Afterwards the scouting parties were taken to the White House, where they were received by President Taft, who was most cordial in his greetings. He commended their project and wished them good luck. After that they were tendered a luncheon by the Washington Automobile Club.

Shore Road

VARIED PANORAMAS IN NEW ENGLAND TOURS

MOUNTAINS, lakes, rivers and a touch of the sea in New England combine to give tourists a diversity of scenery not possible in any other part of America, in a locality where nature has lavished her choicest gifts, all within a figurative "stone's throw" of each other. Such is the characterization given by the New England Hotel Association to the route chosen as "C" of its series of trips through the wonderful land of the Berkshires, White Mountains, Connecticut and Merrimac River valleys. Roads whose construction has been adopted as a model in other parts of this great nation have been selected over which to send the automobilists in search of the beauties of the region, while at the same time keeping them in touch with splendidly equipped hostelries. Such an arrangement has been conducive to extended traveling in automobiles, large and small, until the New England States are probably more toured than any others in the country, and the leaflets issued by the hotel men, assisted by the "Official A.A.A. Automobile Blue Book" have been warmly welcomed by all who have come into touch with them. There are so many possible directions which might be taken in outlining a vacation that frequently the mass of data confuses those who attempt to plan their travels aforetime, and to obviate this possibility the three tours, which embody the most popular features of the section, have been compiled. These show routes which can be taken with the knowledge that the fascinating scenery on one cannot be surpassed upon any of the others and perhaps not in the States north of Long Island Sound.



Tour "A," as described in THE AUTOMOBILE of May 6, consists of a trip of about 1,000 miles through the western portions of Connecticut, Massachusetts and Vermont, then crossing through New Hampshire and Maine to the coast at Portland, following the sea from that city through Boston to Cape Cod and finally westward along the shores of the sound for the run into New York. Tour "B" was explained in THE AUTOMOBILE of May 20, giving a story of a route of about 790 miles in which the Connecticut Valley is followed from Hartford directly north to the mountains, then taking the tourist to the coast at Portsmouth, down to Boston, cutting across to Providence and Narragansett Pier and to the metropolis. All three start from New York City, as the general gateway for parties from other parts of the East and South, and the beginning of a great many tours by New York people. They are so laid out that they can be taken in either direction and between all important cities on these maps are figures which indicate pages in the "Blue Book" where the detailed running directions may be found. The arrangement is further perfected by having the main routes touch each other at various points, sometimes even using the same roads for distances, and this is a feature appreciated by those who know the pleasure of meeting fellow tourists en route.

Tour "C" is planned for those who desire a trip of about 830 miles, including a run through the Berkshire Hills, then up the Connecticut Valley, through the White Mountains, down the shortest, but none the less fascinating, route to Boston, and by the most direct roads to the finish. Great Barrington, Stockbridge, Lenox, and Pittsfield are names of cities so closely allied to the wonderlands of western Massachusetts that the mention of them suffices to picture the delight of a trip through that part of the State. The broad Connecticut is touched at Greenfield, and its famous agrarian vistas surround the tourist as far as White River Junction, when the route makes a detour to Montpelier. After visiting the capital the tour continues to St. Johnsbury and into the mountains. From Bretton Woods Tour "C" travels to Boston, passing the Profile House, the Old Man of the Mountain, through the Franconia Notch and the Flume, Plymouth and Concord. For a long distance the road winds along the Pemigewasset river and fascinating views. At Plymouth a side trip may be made to Lakes Winnipisaukee and Winnesquam, joining the main route again at Franklin, and running along the Merrimac river. The route to New York via Worcester, Springfield, Hartford, and New Haven is well known.

LATE INFORMATION FOR THOSE WHO TOUR

CORRECTION ON ROUTE THROUGH CANADA

There are probably many automobilists who are planning tours for this summer through Canada, and the following letter received from H. E. Newcomet, engineer of maintenance of way of the Pennsylvania Lines West of Pittsburg, bears special interest. Mr. Newcomet says:

"In reading over your 1909 Official Automobile Blue Book, section 1, I noticed on page 681 that you state that during navigation boats connect Ottawa with Montreal and many tourists ship their automobiles that way. I made this trip last summer and I would strongly advise any one in making this trip not to use the Ottawa river boats, as it is necessary to transfer from Grenville to Carillon overland, as the boats do not run through. This transfer is made on a railroad which is very old and primitive and cannot handle automobiles for transfer. Furthermore, the design of the concrete docks at Grenville is such that after unloading the car it is necessary either to build some form of turntable to turn the car and run it up a ramp, as the unloading platform is not more than 15 x 20 feet and you unload at right angles to the ramp. It took us four hours to take a small runabout and a touring car off the boats and get them onto the highway. The distance is about 14 miles and the road so poor that a transfer could not be made in time to catch the boat.

"If the weather in this territory has been good there is no reason why a trip on the north shore of the Ottawa river cannot easily be made in good time, and it is quite an interesting trip, mostly through the French country. If the weather is at all wet, however, or has been wet, I would strongly advise running from Ottawa to Prescott and putting the car on the St. Lawrence River boats for Montreal. The road between Prescott and Ottawa can generally be depended upon, although it is not in any manner a first-class road. We made the trip from Prescott to Ottawa, and Ottawa to Montreal."

NEW PARIS QUARTERS FOR PIERCE

Paris, June 23—American owners of Pierce cars touring Europe have now at their disposition handsome central offices in the Avenue de la Grande Armee, Paris, where spare parts and all information concerning routes, touring regulations, etc., can be obtained at any time. The Pierce Motor Car Company's Paris touring office has been in operation for more than a year, but up to the present has shared office room with a French firm. Owing to the increased number of owners of Pierce cars touring Europe it has been decided to move into larger and self contained offices, and the change took place this week, Manager N. F. Goodsill opening handsome showrooms at the corner of the Avenue de la Grande Armee and the Avenue de la Forge. This is the first time that an American firm has been directly represented on the Paris Automobile Row, and the Pierce company have obtained showrooms in keeping with the importance of the firm. N. F. Goodsill declares that present indications point to a larger number of Pierce tourists than on any previous year, the number up to the present having reported at the Paris offices being about fifty, although the touring season has hardly commenced. Most of the tourists this year are travelling on either the large six or the most powerful four-cylinder model.

CLEVELANDERS PLAN JULY 4 TOUR

Cleveland, June 28—One of the most enjoyable runs of the past few years will be taken by Cleveland Automobile Club members, July 3-4-5, when a three days' trip will be made to Jamestown, N. Y., to spend the Fourth of July. It is expected that at least thirty machines will make the trip. The party will leave Cleveland Saturday morning, July 3. Lunch will be served at the Hotel Cleveland in Conneaut, O., and the cars will reach the Peacock, Mayville, N. Y., for a stop over night. On July 4 the party will proceed around Lake Chautauqua to Jamestown, and it is probable that the night will be spent either in Cambridge Springs or Saegertown. Monday the stop will be at Conneaut Lake, and the cars will return to this city in the afternoon.

FERRY ON SOUND SHORTENS AUTO RUNS

New York, June 28—Automobilists who have hitherto lamented the inaccessibility of Long Island to Westchester county, and vice versa, now have a route which saves many a long run through this city. A frequent ferry service has been established between Oakland Beach, at Rye, and Seacliff in Hempstead harbor, by the Oakland Steamboat Company, which has chartered the large ferryboat Englewood of the Fort Lee line for the season, and it has begun its trips, leaving Rye every even hour, and Seacliff every odd hour between 9 a. m. and 8 p. m. The Englewood will accommodate 25 automobiles at a time without crowding and makes the run across the sound in about 40 minutes. Its pier at Rye is but a half mile down Rye Beach avenue from the Boston Post road. This method of getting from New England points to Long Island, for either the north or south shore, has already proven popular; as well as have certain routes around the city, such as by going up the Hudson to Tarrytown, then across through Westchester county to Rye, crossing the Sound and returning on Long Island. The roads are all fine.

FRENCH COMMISSION TO MAKE NEW ROAD LAWS

Paris, June 23—The growth of the automobile has made necessary a new set of laws governing the use of the highway. This is felt more strongly in France than elsewhere, for, having inherited a magnificent set of highways touring has here grown to an extent unknown in less favored lands. Minister of Public Works Barthoux frankly recognizes that laws drawn up one hundred years ago, when the mail coach was the fastest thing on wheels, and when intercommunication was slight, are altogether inefficient in these days of rapid and frequent travel. "For the new conditions we need new regulations," he declares in an official publication, and to obtain these new regulations he has dedcided on the formation of a temporary commission of experts.

The first meeting of the road laws commission took place in Paris this week at the offices of the Minister of Public Works, under the presidency of M. Leuthier, the general inspector of the department of roads and bridges. The commission comprises high officials in the Government roads department, the chief secretary of the Minister of Justice, Messrs. Max Vincent and Chaix as representatives of the Automobile Club of France; Senator Humbert of the U. V. F., represents cycling interests; while the technical press has as its spokesmen Baudry de Saunier, of *Omnia*, Henry Desgrange, of *L'Auto*, and Georges Prade of *Les Sports*. The recommendation of this special commission will serve as the basis for the elaboration of a modern set of laws and regulations governing traffic on the main highways and busy city streets.

MONTREAL AUTOISTS WORK FOR GOOD ROADS

Montreal, June 28—The directors of the Automobile Club of Canada have gone over the main highway to Rouse's Point, via Chambly, St. John's and Lacolle, and guide boards will be erected without delay. This should not only prove of great service to all kinds of vehicles traversing this mportant and picturesque route, but also should be an inducement to tourists across the border to visit this section of the country. Several pieces of road are in very bad state of repair at present, but it is the purpose of the club to petition the Government, asking that the roads be put in proper order. A map of the above route with detailed information will be ready for distribution shortly. The Automobile Club of Canada is doing excellent work in connection with the good roads movement in and around Montreal, and a large number of stretches of roadways have been repaired and coated with a composition of oil and coal tar at the expense of the club. Although somewhat of an experiment, this has proven successful.

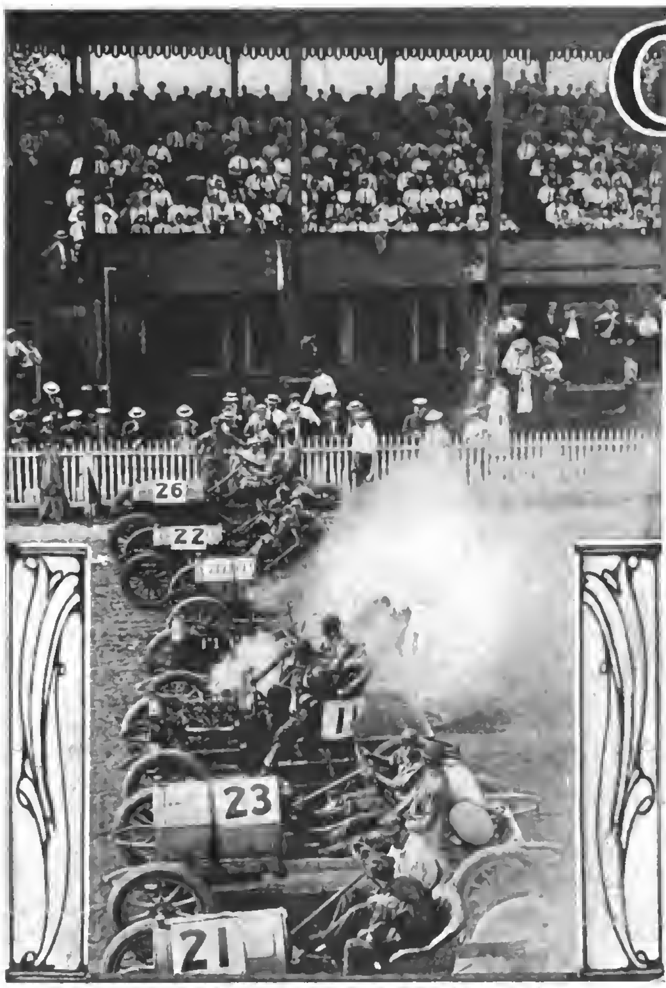
Chalmers Scores in Quakertown's Hundred



Start of the 100-Mile Special Race

PHILADELPHIA, June 28—The recrudescence of automobile track racing in this city, last Saturday afternoon, when the Quaker City Motor Club held its third annual spring meet, at the Point Breeze track, had as its star feature a contest of 100 times around the mile track, in which Harry Lorimer, in a 40-horsepower Chalmers-Detroit Bluebird was an easy winner. In this, as in the other events scheduled, the fields were extremely ordinary and poorly entered, so that Lorimer and Ralph De Palma had matters their own way and about evenly divided the plunder. The work of the little S. P. O., driven by Laurent, and that of the Stearns, driven by Amateur Harry Goodin, helped materially as runners-up, with the Mitchell, Autocar and new Bergdoll as the other makes represented on the course. The one-afternoon program with the 100 and 50 mile races leading figures, had been arranged hurriedly when it was decided to postpone the 24-hour contest first proposed. Lack of interest and entries made the substitution necessary.

There were eight starters in the 100-mile race—the Chalmers-Detroit, two Autocars, a Stearns, the S. P. O., a Buick and two Bergdolls. Lorimer, in the Bluebird, took the lead at the start and was never headed, in fact, making the entire circuit without stopping, and at the finish he was about 11 miles ahead of the second car. The Stearns and the S. P. O. were the important competitors, though for a time the stripped Buick, driven by Jimmy Ryall, figured until it broke a bolt in its crankcase and had to pull out. The Stearns had carbureter trouble, and could not seem to get enough gasoline, and the S. P. O. broke its steering knuckle on the eighty-second mile, when it was in second position. The new Bergdoll cars averaged about 30 miles an hour. With the Chalmers having a good hold on first, the second and third places went to the two Autocars, which had been running very consistently at a good fast pace, driven by Joe Brown and J. A. Archfield. They were so far behind the winner, however, that their times were not taken. Lorimer's 2:02:06 4-5 gave an average speed of about 44 miles per hour. That the going was not faster came through the fact that the winner did not have to push his car, and because the track had been badly cut up by previous short-distance events.

Some Features of the Meet That Were Noteworthy

Some spirited racing took place in the 50-mile race between De Palma in a Fiat, Lorimer in the Chalmers-Detroit, and Laurent in the S. P. O. There were eleven starters, and the Fiat and the Chalmers-Detroit jumped away from the others at the gun, the latter hanging on to the foreigner like a leech. For 25 miles the proverbial 5-A could have covered the pair, especially when Lorimer was attempting to pass. In these numerous attempts De Palma always stalled him off, and just at the conclusion of the twenty-sixth mile, when Lorimer took a short cut to the inside in an effort to secure the lead, his right tire went a-flying across the track. De Palma had garnered a 2½-mile lead when the Chalmers-Detroit left the infield in pursuit. Two laps later the same tire went bad, and De Palma added another mile and a half to his lead before Lorimer could get going again. Meanwhile Laurent, in the S. P. O., had closed the gap and was in second place with a lead of about a mile on the Chalmers-Detroit. Interest then centered in the race for second honors, and although Lorimer took all sorts of risks he could not quite overcome the advantage gained by Laurent during his lay-off, the latter capturing the place by about 200 yards. De Palma's time was 57:43, and he had a lead of 3½ miles over the S. P. O. at the finish. He also registered the fastest five and ten mile times of the day—5:48 1-5 and 11:26 3-5, respectively.

De Palma later added to his worldly pelf when, in an attempt on the mile track record of 1:02 4-5, held by the Peerless *Green Dragon*, Barney Oldfield up, he clipped off an even second with the *Cyclone*, and incidentally captured a cool hundred with the record. He broke into the limelight on his first appearance by capturing the 10-mile event for stock chassis selling for $3,001 and over, covering the distance in 11:46 1-5, holding his nearest competitor safe. Lorimer, in the previous event, $2,001 to $3,000 chassis class, covered the same distance in 11:34 1-5.

In the preliminaries, Cherie Borie, in a Mitchell "20," beat H. H. Crowell in a 5-mile race for equipped cars, $1,250 and less, in 8:16-4-5. In a race of the same distance for equipped cars catalogued at from $1,251 to $2,000, J. B. Ryall, in a Buick "30," pulled away from Archfield's 25.6-horsepower Autocar, and Lorimer's Chalmers-Detroit "30," in 6:44 1-5, winning by nearly half a mile.

Meet Well Conducted and Attendance Fairly Good

The attendance of upward of 5,000 spectators demonstrated that this branch of sport, properly conducted, still has a strong attraction, and despite the intense heat, and not first-class racing, the people many times were brought to their feet in roaring acclaim of some particularly pretty bit of driving. It was the general opinion that there was a great deal of credit due to the officials of the club for the manner in which the meet was conducted, witness the fact that it was just 1:30 p. m. when the first event was started, as had been advertised. The crowds and newspaper men, however, were a trifle sore over the unwillingness or inability of the clockers—the New York Timing Club—

to hand out the intermediate times in the long-distance races. It has been the custom here to announce the time at each five miles. It is a good scheme, too, as it tends to keep the crowds busy with their pencils and adds to the interest. With no intermediate announcements, the 50 and 100 mile events became rather dismal, especially as the winners in both instances finished miles ahead. When, finally, the 5-mile times were handed privately to the pressmen in the judges' stand, they were so suspiciously "flat" as to raise a doubt as to their accuracy, many of them being on the even minute. Following is the summary:

100-MILE SPECIAL, CASH PRIZE $200

No.	Car	H.P.	Driver	Time
1	Chalmers-Detroit	40	Harry Lorimer	2:02:06 4-5
2	Autocar	25.6	J. F. Brown	
3	Autocar	25.6	J. A. Archfield	

50 MILES, CHASSIS, FREE-FOR-ALL

1	Fiat	60	R. DePalma	:57:43
2	S. P. O.	18-24	Laurent	1:01:05 3-5
3	Chalmers-Detroit	40	Harry Lorimer	1:01:09 4-5

10 MILES, CHASSIS, $3,001 AND OVER

1	Fiat	60	R. DePalma	11:46 1-5
2	Stearns	30	Harry Goodin	12:23 4-5
3	American	50-60	Harry Willis	12:27 3-5

10 MILES, CHASSIS, $2,001 TO $3,000

1	Chalmers-Detroit	40	Harry Lorimer	11:34 1-5
2	S. P. O.	18-24	Laurent	13:10

5 MILES, EQUIPPED, $1,251 TO $2,000

1	Buick	30	J. B. Ryall	6:44 1-5
2	Autocar	25.6	J. A. Archfield	7:22 2-5
3	Chalmers-Detroit	30	Harry Lorimer	7:23 3-5

5 MILES, EQUIPPED, $1,250 AND LESS

1	Mitchell	20	Cherle Borle	8:16 4-5
2	Mitchell	20	H. H. Crowell	8:45 3-5

1 MILE TIME TRIAL, TO BEAT TRACK RECORD (1:02 4-5) CASH PRIZE $100

1	Fiat Cyclone	60	R. DePalma	1:01 4-5

CLIMBED SUNSET HILL IN WESTCHESTER

Ossining, N. Y., June 28—The Upper Westchester Automobile Club had its first climb, Saturday, on Sunset Hill, near here, with a good field and some fast time in the six classes. Over a course seven-tenths of a mile long, with a grade varying from 6 to 12 per cent., an Atlas, driven by E. H. Sherwood, carried off the real honors for making the fastest time in the stripped stock chassis event. Atlas, Renault, Stoddard-Dayton, Chalmers-Detroit "30" and Maxwell won in their respective classes, while the free-for-all was taken by a steam car. There was one sharp turn in the hill, and it caused considerable skidding. The winner in each class received a silver cup. Summary:

STRIPPED STOCK CARS

Pos.	Car	Driver	Time
1	Atlas	E. H. Sherwood	1:02 3-5
2	Maxwell	William Sickinger	1:06 2-5
3	Renault	E. H. Ennis	1:15 4-5
4	Ford	T. E. Wilson	1:18

CARS COSTING $3,000 AND OVER

1	Renault	E. H. Ennis	1:06 4-5
2	Howard	Burrows McNeir	1:23 4-5

CARS COSTING $2,000 TO AND INCLUDING $3,000

1	Stoddard-Dayton	F. Crowther	1:14 3-5
2	Chalmers "40"	A. L. Washburne	1:33 1-5
3	Atlas	E. H. Sherwood	1:42

CARS COSTING $999 TO AND INCLUDING $1,500

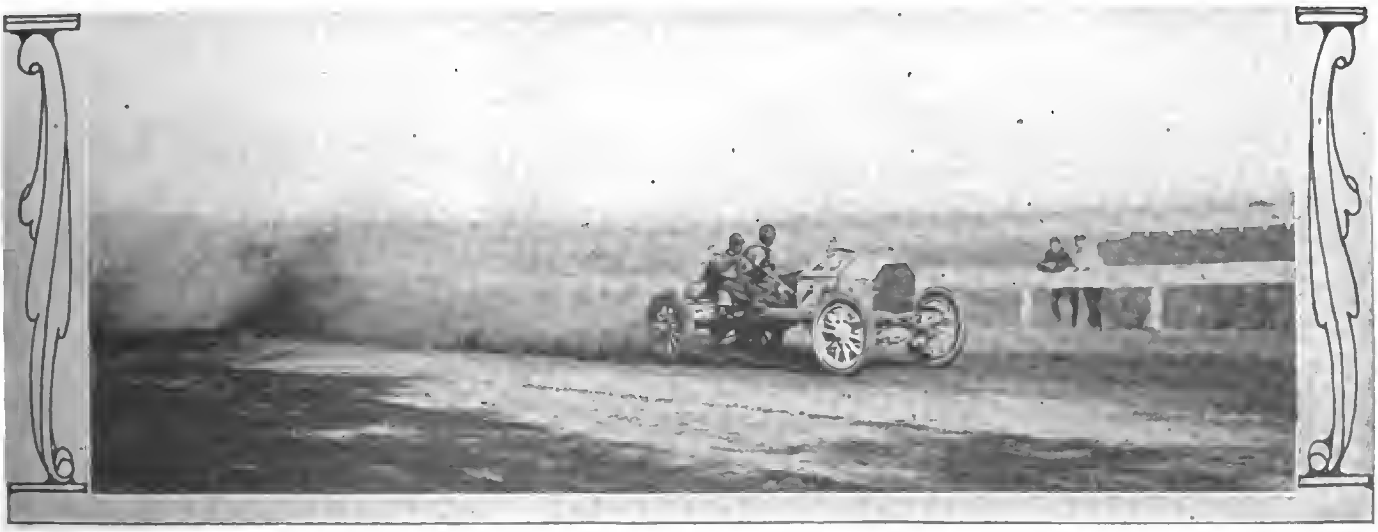
1	Chalmers "30"	A. L. Washburne	1:21 3-5
2	E-M-F	W. S. Smith	1:29
3	E-M-F	Almery and Paul	1:30
4	Buick	Walter Horton	1:32 2-5

CARS COSTING $999 AND UNDER

1	Maxwell	William Sickinger	1:13 4-5
2	Maxwell	Arthur Lee	1:24 1-2
3	Ford	F. E. Foshay	1:34 2-5

FREE-FOR-ALL

1	Stanley Steamer	Harvey W. Bell	:58
2	Atlas	E. H. Sherwood	1:02 3-5
3	Peerless	Ray Gilhooley	1:13
4	Howard	Burrows McNeir	1:19 1-5



Winning Chalmers with Lorimer at the Wheel, Rounding the Turns at Point Breeze in the 100-Mile Special Race

Cars Taking Ferry at Nyack En Route to Newburg

BINGHAMTON'S RUN EMPHASIZES "SIXES"

BINGHAMTON, N. Y., June 26—Four, and perhaps five, perfect scores are the result of the fourth annual endurance contest of the Binghamton Automobile Club, which finished a trip of about eight hundred miles this evening. Two new six-cylinder Mathesons, a six-cylinder Thomas and a four-cylinder Cadillac have clean titles, and it is likely that a six-cylinder Pierce-Arrow which dropped the lid of a battery box may also be put among those in the deadlock for premier honors. For five days of the past week these automobiles, four other contestants, and one official car have been driven over the roads of four States, visiting the capital of each, and spending one day of rest in the "Hub." Rules had been framed which gave the event the interest of a competition without drudgery.

Monday morning last the caravan, consisting of ten autos, left Binghamton for Albany, a distance of 142 miles, with an intermediate stop for luncheon at Worcester, N. Y.; Tuesday they journeyed to Boston, 187 miles, with the noon control at Springfield; Wednesday was taken for sightseeing, under the guidance of a regular "Seeing Boston speiler," who informed the autoists that Boston streets are paved every 50 years, and that they are now in their forty-ninth. Answering the call of the road on Thursday, the route to Hartford was taken, a run of 116 miles, a midday stop being made at Providence; Friday led to Newburg, through Tarrytown, 144 miles, and the home stretch was 169 miles long, from Newburg to this city, lunching in Delhi.

George F. Johnson, the donor of the trophy, led the way as pilot in his six-cylinder Stevens-Duryea, and he kept right ahead through the tour, except once, when another car took a short cut. The others in the party were:

William G. Faatz, Thomas; C. Fred Johnson, Matheson; Charles F. Sisson, Jr., Pierce-Arrow; G. Somers White, Matheson; Harry T. Conant, Packard; Dr. Jeremiah McDonald, Cadillac; R. E. Mix, Thomas; G. Tracy Rogers, Locomobile, and Hiram Goldsmith.

Six-Cylinder Stevens-Duryea Pilot Car
Baldwin at the Wheel, and George F. Johnson, T. W. Whipple and J. M. Kennedy other occupants of the car

Of these the Faatz Thomas, the two Mathesons, and McDonald's Cadillac made the entire run on time, never having to stop for mechanical and other trouble, except tires once in a while, and their records were clean in every way. On the last day the battery box lid of the Pierce fell off, necessitating a stop to go back for it, and the observer's record of an adjustment. The Packard was penalized for an adjustment to a small forging which gave way, and the Locomobile withdrew because tire trouble had made it very late on the first day and had increased penalties on the second. Because he refused to change observers, as required by the rules, the Mix Thomas was dropped from the contest, but completed the run as a non-contestant. The Goldsmith party refused to run faster than fifteen miles per hour and averaged lateness by the hour on each day, reaching the finish about five hours behind.

A great deal of credit has been given the cars which made this trip, for there were many places where they were well tested, on muddy or rough roads, in climbing mountains, or in making detours around road-building operations. The Matheson Sixes made their first appearance in road endurance contests and showed up exceptionally well.

George Somers White in Six-Cylinder Matheson

The committee will meet to decide upon some method of breaking the tie, and also as to whether it shall be four or five-cornered. Two proposals have been made, one to have a further test and the other to allow the owners of the perfect machines to vote the trophy to one of their number.

FORD NO. 2 WINS RACE TO SEATTLE

SEATTLE, WASH., June 29—Ford runabout No. 2, driven by B. W. Scott and C. J. Smith, has won the ocean-to-ocean run. For 22 days 55 minutes this little car was on the road from New York, and reached this city on last Wednesday, well ahead of any of its competitors. The Shawmut, driven by T. A. Pettingill, Earl Chapin, and Robert Messer, was second, about eight hours later; and the Ford No. 1, piloted by Frank Kulick and H. B. Harper, arrived third, on Friday morning. The Acme, handled by George Salzman, F. R. Sheets, Jerry Price, and J. A. Hemstreet, arrived this afternoon.

Decided uncertainty as to the exact winner has prevailed since the first cars came in. The Shawmut crew protested the leading Ford on three scores—first, for crossing a bridge where the Shawmut was delayed 16 hours, because the latter did not have permission; second, for allowing an outsider to take the wheel in Snoqualamie Pass; and third, for changing a rear axle. Referee Robert Guggenheim investigated the charges and did not sustain them, making known his decision to-day. Therefore the Guggenheim trophy with $2,000 will go to the Ford crew, and $1,500 to the Shawmut.

Summit of Ives' Hill, Near Meriden, Conn., Scene of the Recent Hill Climbing Contest

CORBIN WINS CLIMBING HONORS NEAR HOME

MERIDEN, CONN., June 26—Twice during the afternoon a Corbin piloted by B. C. Rogers excelled its rivals in climbing Ives Hill. Though it captured the free-for-all in .45¾, its best ascent was accomplished in its class event with figures of .45¼. Although open only to local owners, the event was exceptionally well managed, and the half mlie course was guarded by State militia, the guardsmen being from Company I of the Second regiment. That this kind of sport is popular in Connecticut, the third climb within a short while, was shown by the presence of several thousand spectators, some from New Haven, New Britain, Hartford, and other cities. The cars, many of them stripped and tuned, were divided into classes by piston displacement.

For the big car class, those between 301 and 400 cubic inches, a Thomas-Detroit was the victor, driven by Percy Callington, in .47½, and another of the same make took second, Albert Eichorn at the wheel. It was in the section for cars of from 231 to 300 cubic inches that Rogers scored first, and it developed, the fastest of the afternoon, in .45¼, with C. A. Terrell in a Pope-Hartford, the runner-up. Four cylinders won over the two-cylinder variety in an event for autos whose displacement rated between 161 and 230, for a four-cylinder Ford, driven by Adam Englehardt, made the ascent in 1.10½, defeating a double-opposed Reo handled by Arthur E. Cook.

Two Maxwells had the little-car section to themselves, that with less than 160 cubic inches in their motors, and Harry Smart ranked the better in 1:13, his competitor being R. J. Merriam.

As a climax came the free-for-all, which, as usual, furnished a surprise. It was not that of a record-breaking rush, however, for Rogers' Corbin dropped one-half a second somewhere on the route over its best previous time. Thus the record for the open event stands at .45¾, but not the record for the hill. A twin-cylinder Indian, handled by Joseph Allaire, negotiated the distance in .40½, carrying off the palm for the two-wheelers.

So pleased were the officials and the club members that already plans are being formulated for a repetition later in the season. The officials were: Referee, Charles Cuno; starter, B. L. Lawton; judges, J. H. White, E. J. Doolittle, C. B. Rogers, George M. Curtiss, John S. Lane.

FIRST HILL CLIMB FOR RICHFIELD SPRINGS

RICHFIELD SPRINGS, N. Y., June 28—Under the auspices of the "Earlington," a first annual hill climbing contest will be held here on July 31. A course 5,000 feet long has been selected, and will be adequately policed. There are nine events, with a valuable trophy presented by Gasherie DeWitt for the free-for-all. The event has an A.A.A. sanction.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

ARE THE PARKS FOR THE PEOPLE OR NOT?

Incredible as it may seem, it is a fact that the great Yellowstone Park, purchased and kept out of the public moneys, and offering without a doubt the greatest trip in the country, is actually impassable to one great division of the people, and that division is the automobile driving and riding public. What possible harm or damage these machines or their occupants could do to the natural wonders of the Park, which horseback riders or other travelers could not do, is hard to imagine.

The automobile is essentially a vehicle for covering long distances in a comparatively short time, and with comfort to its occupants. On a trip through this immense reserve of natural wonders, what is more natural than such a means of conveyance?

Moreover, this swift means of locomotion would materially decrease the running time between the usual stops, and in this way render the use of the Park more safe. If motor cars had been permitted at the time of the recent holdup in the park, it is a fair assumption that the robber would never have escaped, or the robbery would never have taken place. As a preventive of crime alone, then, the machines should be allowed the freedom of the Park.

But, more to the point, the common people to whom the Park, in the last analysis, belongs, should have the use of it, whatever the means of conveyance employed by them. It would appear as if some very strong element, directly or indirectly interested in the transportation companies, was using all of its power to keep out any form of transportation which would reduce their monopoly and consequently their revenue.

It seems a shame that the property of all the people should thus be made a source of revenue for a few favored ones. Every automobile association and club, as well as influential owners and drivers not members of any club or association, should use every endeavor to have this matter brought up and remedied at once through their representatives in Congress. This discrimination should be stopped, and quickly, as it is rank class discrimination and has no basis of sound common sense.

* * *

STATISTICS THAT CAUSE REFLECTION

Some 200,000 automobiles is the estimated output for the so-called "1910" product. These figures are somewhat staggering, but from present indications it would appear that the total is based on a substantial optimism resulting from the excellent "1909" selling season.

There isn't any question but that this great country is going to absorb thousands of automobiles in the next few years, for thousands of users of horse-drawn vehicles are yet to be supplied with the inevitable motor-driven successors.

But one cannot resist the inclination to utter a word of caution in safeguarding against any such calamity as an over-production, for 'tis better to have the supply fall below the demand than that the output should flood the natural sources for absorption of the product. True, the equilibrium would quickly be regained, but the damage accomplished in the interval would be ultimately at the cost of the many.

* * *

WE WILL PAY IF YOU'LL PAY

Why shouldn't horse-drawn vehicles be taxed as well as motor-driven ones? This question has been argued pro and con among autoists, and has even reached the stage where it can be taken up by country debating societies. The Automobile Club of Maryland has taken a determined stand in the matter; so determined, in fact, that a proposed automobile law may hang fire for some time. In that state a commission was appointed to confer with the automobile interests, and the commission and the club have outlined their views in different channels; the former along the cut-and-dried ways of fees on power and the latter agreeing provided a wheel tax is imposed upon the other users of the highways.

Naturally the agricultural interests do not wish a wheel tax when the farmers have to pay road and other taxes. But a new era is establishing itself, and the majority are realizing that automobiles are not half bad, after all. Now comes the stand of the autoists who agree to pay a license fee, graded according to horsepower, from six to fifteen dollars, provided that a "wheel tax is imposed upon all other vehicles within the State at a rate of 25 cents per wheel for one-horse pleasure vehicles, 50 cents a wheel for two-horse vehicles and one dollar a wheel for vehicles with four or more horses; and further, that all vehicles must carry lights at night."

WHAT NEW MASSACHUSETTS LAW CONTAINS

BOSTON, June 28—Massachusetts' new automobile law, prepared by the Highway commission and passed by the legislature after long hearings and numerous conferences with autoists and others interested, has been signed by Governor Draper and a part of it will go into effect the first of next month. The main part of the law, including the sliding scale of fees based on horsepower, will become operative January 1, 1911.

Four sections go into effect the first of July, namely, sections 7, 14, 16, and 17. Section seven makes it incumbent for owners to look after the equipment of their cars, requires that every motor vehicle of more than 10-horsepower shall be provided with at least two brakes, powerful in action and separated from each other, one brake to act directly on the driving wheels or on parts connected with the wheels. Each of the brakes must be strong enough to stop the vehicle within a proper distance, and one must be operated by foot. One brake is required for motor vehices not exceeding 10-horsepower, and for motorcycles. The section has the usual requirements as to the muffler and signaling apparatus, and in addition requires that every car shall have a lock or rachet brake to prevent its being started by unauthorized persons.

Some General Provisions of the New Code

This section makes a change in the matter of lighting. Under the present law lights must be displayed from an hour after sunset to an hour before sunrise; the new law makes the time allowance one half-hour. Every automobile must show two forward lights, but they need not carry the register numbers as is now required. The rear register number, however, must be illuminated and a red light must be shown behind. Every motorcycle must show a white light and it is stipulated that the white lights must be visible two hundred feet. Section 14 of the new law puts upon the operator a new responsibility in regard to other users of the highways. It provides that an operator must stop his vehicle and the engine immediately when approaching a horse or other draft animal if the animal appears to be frightened and if the preson in charge signals. A new clause requires that an operator in approaching or passing a street car which has been stopped to allow passengers to alight or embark, shall slow down and, if necessary, stop. Upon approaching a pedestrian who is not upon a sidewalk, and upon approaching an intersecting way, a curve, or corner where the operator's view is obstructed he must slow down and signal with a bell, horn or other device. This part of the law also requires operators to make square corners. Observance of this section, especially that part which requires signaling upon approaching a pedestrian is expected to prevent many accidents, but if strictly followed will create considerable din in the city streets.

Speed Limit Section Not Materially Changed

The speed limit section, number 16, goes into effect July first, but this is not greatly different from the existing law. The maximum limit remains at twenty miles an hour. The limit for the thickly settled or business sections, however, has been increased from twelve to fifteen miles an hour and the limit at crossings of way, corners, and curves, remains at eight miles. One of the most important parts of the law from the autoist's point of view, and also to the cities and towns, is section 17. Under this section, after next Thursday, every local regulation excluding automobiles from streets, or making special speed limits, except the local regulations of the island of Nantucket and those of the Metropolitan park commission, becomes null and void, and the local authorities are required to remove all signs and notices relating to the speed, operation and use of automobiles. The effect of this provision is to put the entire State, with the exceptions noted, under the State limits of 20, 15, and 8 miles an hour. If the local authorities believe that special regulations excluding automobiles or limiting their speed are still necessary, they may pass them, but they will not have any effect until they have been published in the newspapers, posted at points affected, and, most important of all, until they have been approved by the Highway commission as consistent with the public interests. No regulation will be valid which excludes automobiles from any State highway or from any main highway leading from any city or town to another. This part of the law gives the autoists the opportunity to protest against special regulations, which they consider onerous, without being under the necessity of preparing the elaborate protest required by the old law. Its effect, further, will be to bring about uniformity throughout the State in the matter of speed limits.

License Fees Are Based on the Horsepower

The Highway commission has not yet given much attention to the question of how it will determine the horsepower of motor vehicles for the purposes of registration next year, but it seems likely that it will use the A. L. A. M. formula, which seems to be the best available.

The fees for next year are $2 for a motorcycle, $5 for a truck or other commercial motor vehicle, $5 for automobiles of less than 20-horsepower, $10 for automobiles of 20- and less than 30-horsepower, $15 for automobiles of 30- and less than 40-horsepower, $20 for automobiles of 40- and less than 50-horsepower, $25 for automobiles of 50-horsepower or more; for automobiles owned by manufacturers or dealers, $25 for five cars, and $5 for each additional car; for motorcycles owned by manufacturers or dealers, $10 for ten cycles; for registration after October 1, one-half fees; for substituting the registration of an automobile for that of a vehicle previously registered $2; for substituting the registration of a motorcycle for that of a cycle previously registered $1; for original operator's or chauffeur's license $2; for renewal of license 50 cents; for examination of applicant for a license $2; for additional copy of registration certificate 50 cents; for additional number plate 75 cents; for additional motorcycle seal 50 cents. Free eertificates and licenses may be issued to members of the foreign diplomatic corps. All licenses to operate will be for one year only, as is the case with certificates of registration.

Minor Changes That Were Made in the Law

Very little change was made in the law during its passage through the two houses of the Legislature. The most important change was an addition to section 3, which allows a rebate to a person who before August first transfers the ownership of an automobile registered in his name, and who applies for the registration of another automobile of less horsepower, of one-half the difference between the fees, and if he does not apply for another registration he will be entitled to a rebate of one-half the fee originally paid. Another change is in the section relating to the record of cars entering or leaving garages. The change relieves chauffeurs of the necessity of personally entering their time of leaving and other data required to be kept in the record book. The new law will give the Highway commission much additional work, but it will mean a large increase in the receipts of the State. Probably about one-half of the automobiles in the State will pay $5 a year, as is the case under the existing law, but the other half will be required to pay from $10 to $25 each. Furthermore the annual renewal of licenses to drive is expected to bring in considerable income. After the expenses of the automobile department of the Highway commission are paid all the balance of the fees will go into the State highway maintenance fund. This fund will also be increased by the fines received for infractions of the automobile law, for the new statute provides that all these fines shall go into the State treasury, instead of the cities, towns and counties, as is the case at present.

CLARKSON SUCCEEDS CHALFANT IN A. L. A. M.

Coker F. Clarkson has been elected assistant general manager by the board of managers of the Association of Licensed Automobile Manufacturers to fill out the term of E. P. Chalfant, who recently resigned as general manager to become identified with the Packard Motor Car Company. Mr. Clarkson has been connected with the association for some time in the mechanical and publicity departments and has been in close touch with its affairs. The following members of the board were present at the meeting in New York on Friday: M. J. Budlong, Packard; Charles Clifton, Pierce-Arrow; L. H. Kittredge, Peerless; Thomas Henderson, Winton; F. B. Stearns, Stearns; E. L. Thomas, Thomas; C. C. Hildebrand, Stevens-Duryea; S. T. Davids, Jr., Locomobile; H. H. Franklin, G. H. Stilwell, Franklin; William E. Metzger, E-M-F; J. H. Becker, Elmore; W. C. Leland, Cadillac; James Joyce, A. L. Co.; Elwood Haynes, Haynes; F. C. Chandler, Lozier; E. R. Hewitt, Hewitt; George Pope, Albert Pope, Pope; R. H. Salmons, Selden; George J. Dunham, Royal Tourist; M. S. Hart, Corbin; L. J. Hart, Waltham; W. C. Durant, Buick; G. E. Mitchell, Alden Sampson; E. P. Chalfant, general manager.

Coker F. Clarkson

PROLONGED TRIAL OF WINTON SELF-STARTER

Baltimore, June 28—The Winton Motor Carriage Company reports to-day that it was compelled to break the seal that as far back as February 22 was placed on the front of the Winton Six used in this city for demonstration purposes. This was sealed by Frank W. Daring, secretary of the Automobile Club of Maryland, in the presence of i distinguished gathering of automobile enthusiasts.

It will be recalled that the engine was so sealed as to make it impossible to start except by the Winton mechanical self-starting arrangement, fitted to all Winton cars since the commencement of 1908. The car has been in continual use since it was sealed, and until to-day never failed to start by the pressure of a button. To-day, while the car was in use by the officials of the Good Roads Commission, the engine, upon being asked at Laurel, failed. B. B. Tatham kept the button pressed, the engine turned over and over and over, but did not fire. After several ineffectual efforts and after all the pressure had been usd from its starting tank, it was decided to break the seal, and while there were no tears shed, Tatham was considerably bowed down with sorrow.

Upon return to Baltimore the apparatus was examined and found to be in perfect order, the trouble being located at the battery, which had exhausted itself, owing to a piece of copper wire having short-circuited the same. It should be observed that although the Winton Six is fitted with the Eiseman Magneto, yet it has the ordinary coil and accumulators for starting purposes.

KNOX TIRE TROUBLES EXAGGERATED

Chicago, June 26—First reports of a race often get a little bit twisted when it comes to specifying the exact behavior of a car. For instance, Bourque and Denison, the Knox team, in the Cobe cup race, are learned to have had a minimum of tire troubles. Bourque finished with the original Knox tires on his front wheels and only made a change of the two rear tires on the twelfth lap, which occupied less than two minutes. Denison, during his brilliant run, only changed one tire, and this was accomplished on the road in a little over a minute. It is natural that the Fisk Rubber Company should want marked attention called to the revised findings of the tire experience of the Knox team during the race.

STATE LAW IS HELD SUPREME IN OHIO

Columbus, O., June 28—A decision far reaching in its effects has been handed down by the Supreme Court of Ohio by which the municipal ordinances providing for licensing motor cars were declared unconstitutional. The decision in effect does away with all regulative legislation on the part of municipalities, placing that power in the hands of the General Assembly through the State automobile department.

The decision is the outcome of a strong fight put up by the Columbus Automobile Club against the city law department of Columbus. City Solicitor Marshall attempted to enforce the municipal ordinance, providing for a tax of $7.50 on touring cars and $5 on runabouts. The Columbus Automobile Club in the name of William Frisbie, one of its members, started a suit, and an injunction against collecting the fees was granted. In the Court of Common Pleas and in the Circuit Court the automobile club was worsted. But, never daunted, the case was appealed to the final tribunal with the result above stated.

The decision will effectually stop all municipalities of the State from imposing licenses or taxes on motor vehicles.

NEW SMALL CAR FOR ENGLISH DAIMLER

Coventry, England, June 22—Thoroughly satisfied with the performances and public reception of the 22 and 38-horsepower slide valve engines, the English Daimler works has now brought out a small model of 15-horsepower, embodying all of the main features of Daimler design, including the Knight-Daimler slide-valve engine. This will be of 78 mm. (3 1-16) bore by 100 mm. (3 15-16) stroke. Two distinct models will be marketed, both with shaft drive, and the usual three-speed gear-box, following the 22-horsepower model very closely. One of the models will be fitted with a very raking steering post and torpedo body for those desiring a fast runabout. A large number will be produced and sold next season for £500 ($2,500), it is understood. The output of the two larger sizes will not be diminished any on account of this newer model.

FRICTION DRIVE PATENT SUIT DECIDED

Boston, June 28—Some months ago the Buckeye Manufacturing Company, Anderson, Ind., makers of the Lambert cars, brought suit against the Waltham Manufacturing Company, Waltham, Mass., for alleged infringement of the patents of the former covering friction driving. This suit has been on in the United States Circuit Court of Massachusetts, and was just decided recently. Justice Colt, in rendering a decision, held that the patent was valid, and had been infringed by the defendant. The latter was therefore enjoined from further use of this device and was required to pay $1,000 damages.

CHEVROLET USED STROMBERG CARBURETER

Chicago, June 26—Chevrolet, who evolved as the winner of the Cobe cup, employed a Stromberg carbureter on his Buick, and not one of another make, as was erroneously printed in the June 24 issue. The first information came from an official of the Buick Company, who apparently was not thoroughly informed in the premises. The Frenchman reports that the carbureter did not give a particle of trouble.

SAVANNAH GETS RENAULT TAXICABS

Savannah, Ga., June 28—This city's first taxicabs, ten Renaults, arrived Friday, and the Savannah Taxicab Company has already started them on the streets. The cars will be kept in a spacious garage on Broughton street, erected for the purpose, and the concern, in addition to the taxi business, will store and sell automobiles and sundries.

What the Clubs Are Doing These Days

BUFFALO HAS RECORD ORPHANS' DAY

BUFFALO, June 28—Last year the Automobile Club of Buffalo had an Orphans' Day celebration which broke all records, and it was thought that it would stand, but on Wednesday the previous achievement was shattered. With 275 automobiles in line, 2,289 children were given an outing, the greatest number of little folk ever gotten together on such an occasion. The plans had been well made and included a long ride through the city and parks, and an afternoon of delight at Luna Park. Not only were the private automobiles of the city out in force, but the factories donated all that they had, various labor and other organizations hired cars, and the taxicab and sightseeing companies contributed, so that the large total was made up.

John M. Satterfield, president, and Dai H. Lewis, secretary of the club, had charge of the outing, and felt well paid for all the work such a successful affair involved when they led off the procession after a parting "Godspeed" by Mayor J. N. Adam.

Mayor Adam Giving President Satterfield the Word

Every orphan had a small flag in one hand, and in the other held captive a struggling toy balloon, contributed by the Diamond Rubber Company. The ride was over Main street to the Terrace, thence past the City Hall, where the city officials reviewed the parade, then over 25 miles of asphalt-paved streets, through the various public parks and parkways, to Luna Park, where each little guest was given the freedom of the place and all its amusement resorts, besides sandwiches, bananas and milk.

On July 7 the Automobile Club will conduct a one-gallon mileage contest for pleasure cars, under an A. A. A. sanction. There will be five classes under the present rules, and in each class will be two divisions—one for private owners and the other for manufacturers and agents. Entries will close on July 5, and blanks, rules and information may be obtained from the chairman of the contest committee, Laurens Enos, 760 Main street.

SHAMOKIN'S "25" FORM AUTO CLUB

SHAMOKIN, PA., June 28—Twenty-five automobile owners of this place have formed the Shamokin Motor Club, and a charter has been applied for. It is expected that within a short time there will be at least 50 members of the organization, and the Pennsylvania Motor Federation will be joined. The following officers were elected: President, C. Q. McWilliams; first vice-president, Thomas Mullen; second vice-president, George Robertson; secretary, George W. John; treasurer, Frank P. Llewellyn. Suitable quarters for the club will be secured.

LONG ISLANDERS INCREASE MEMBERSHIP

BROOKLYN, June 30—Campaigns for increased membership in the Long Island Automobile Club, of automobilists of this city and vicinity, have been wonderfully successful during the spring and early summer. At the regular monthly meeting of the club last night, 39 new members were elected, and there are a number of applications to be posted for the required 10 days, to be acted upon at the next meeting. In answer to a number of inquiries for a route from the club house to the Queensboro bridge, the touring board has advised the following: North on Bedford avenue to the fountain, turn left around the fountain and then right into Berry street, keep straight out Berry street bearing left into Lorimer street at the end of Berry street, straight through Lorimer to Noble street, which is at the end of Lorimer street, turn right one block to Manhattan avenue, turn left on Manhattan avenue, granite block stone pavement (poor), straight across Vernon Avenue bridge, turn right first street on leaving bridge, and then left into Jackson avenue straight to the Bridge plaza.

COLUMBUS GIVES 1,600 CHILDREN OUTING

COLUMBUS, O., June 28—The Columbus Automobile Club, June 24, gave an outing to more than 1,600 children, many of whom were orphans, at the grounds of the Columbus Country Club. The affair, which has become an annual event, was a success in every particular. The start was made from the State House grounds at 8 o'clock. Each child was provided with a ticket telling the car in which it was to ride, and these were distributed by officers of the Salvation Army and the Volunteers of America. A short parade of the streets of the city was made before the pike to the Country Club was reached. The car of Governor Harmon headed the parade and that of Mayor Bond followed. Arriving at the Country Club, each child was given a lunch-box containing many dainties and sweets. The return was made in the afternoon.

PATERSON WILL HAVE SEALED-BONNET RUN

PATERSON, N. J., June 28—The North Jersey Automobile Club of Paterson has decided not to hold a hill climb, on account of the danger attending affairs of this kind, and to schedule a 100-mile sealed-bonnet contest for July 17. The run will be in four laps of 25 miles each, and part of the route will be along the main street of the city. A committee consisting of Jacob von Der Clock, chairman; Edward D. Conover, Harly B. McGinley, and James Schofield, will have charge of the run.

SOUTH BEND, IND., NOW HAS AUTO CLUB

SOUTH BEND, IND., June 28—At a recent meeting in the banquet hall of the Oliver Hotel the South Bend Automobile Club elected the following officers: President, L. P. Hardy; vice-president, Walter A. Hager; secretary, Samuel B. Robinson; treasurer, Jacob Woolverton. E. C. Witwer, H. M. Kaufman, and Dr. George V. Nienstedt were elected to serve with the officers as a board of governors. The club now has a membership of 50 and is hustling to increase to 100 or more.

ALBANY CLUB HAS FIFTH ANNUAL RUN

ALBANY, N. Y., June 28—The fifth annual tour of the Albany Automobile Club finished this afternoon. The tour was entirely a pleasure event, without any competition, and the route was a scenic one, including the Green and White mountains, the Berkshire hills, and the Atlantic shore above Boston. The cars started on June 22.

This Kentucky Product Is a Thoroughbred, Too

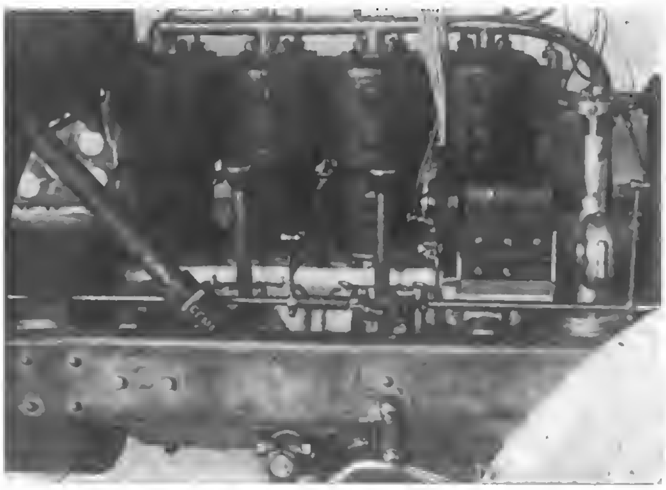
NEWCOMER FROM THE BLUEGRASS REGION

There are very few motor cars manufactured in the "Sunny South," so that the few are more noticeable than would be the case were their number larger. One of them, the most recent addition, by the way, is worthy of special attention, and its product, equally so. This is the Lexington Motor Car Company, Lexington, Ky., which is announcing the details of its Model A touring car, the output for this year being confined wholly to the one model.

Rather than use an indifferent lot of parts, as constructed in their own shop, the same having been running but a few months, the company have given prospective customers the benefit of the doubt, and will use only tried and proven parts as made by the country's best specialists in those particular lines.

So it is that Model A is seen to be powered with a 40-45 horsepower engine of the famous Rutenber make. The size of this is four cylinders, 4 1-4-inch bore and 5-inch stroke, the cylinder castings being made individual for easy and cheap replacement, if necessary. This engine is too well known to require mention of all of the details, but it may be worth while to state that it is of the standard water-cooled type, with five bearing crankshaft of large diameter, double ignition, if specified, a vertical shaft in front forming the source of power for all accessories except the fan, which is belt-driven from the extension of the crankshaft. This accessory shaft drives in succession, from the bottom up, the oil pump, magneto, and the timer. The latter is used with the battery system, which is regularly furnished, but provision is made for a magneto, and the Bosch will be fitted as an extra.

Clutch Merits Attention—A very large flywheel fitted to the motor makes for continuous turning effort and houses the clutch as well. The latter is of the regular cone type, fitted with cork inserts, the action of which is to give easy engagement, coupled with great holding power. Back of this is the transmission, which delivers no less than three speeds and reverse, operating on the selective principle. The gear shifting is done with the inner lever at the right side, this being of the ball-ended style and operating in an H-slot. The transmission shafts are both mounted on ball bearings of the Hess-Bright make, with the driving shaft located above the countershaft.



Ignition Side of the Motor, Showing Bosch Magneto

From here to the rear axle, the drive is through the medium of a very large propeller shaft. It has a universal joint at each end, which joints act to nullify the strains of the angular drive. The rear axle is one of the Timken masterpieces, being of the full floating type, the wheel drive at the outer ends taking the form of six-jaw clutches. In order not to have any of the loading strains come upon the driving shaft, the arrangement is such that the casing, a solid steel casting, without strut rods, carries all of the weight. Differing from the rear axle in the form of service, which it must render, the front axle is given a different form, that of the I-beam. Upon this the front wheels are carried through the medium of tapered roller bearings.

The cross rod is carried back of the axle, so as to be protected from injury, and the steering rod is above the I-section for the same reason. Steering is effected by a gear of the Gemmer production, which acts on the double worm principle.

Frame Follows a Popular Shape—The main frame of the car is of pressed steel, of channel section. In its form it follows a popular shape, being straight in both a horizontal and vertical plane, back to the rear axle, where it is given a sharp upward bend to clear the axle and give sufficient room for a large rebound effect. The forward portion carries a sub-frame upon which the engine and transmission are hung. This frame is connected to the axle by springs of the semi-elliptic type. The same style of spring is used both fore and aft, the two differing only in length. The fronts are 40 inches long, and the rears 52. They are assembled from a very wide stock, with all leaves lipped, and before assembling are well lubricated with graphite. The hanging is by double shackles.

Timken Rear Axle Used on Lexington Model A

Very large wheels are used, 36 inches throughout, and equipped with 4-inch tires. The front wheels have 10 spokes and the rears 12, these being of the dovetailed and interlocking type, which, coupled with the dished shape, make the strongest wheel that has ever been produced. To the rear wheels, the large diameter brake drums are bolted, with a bolt to each spoke. These brakes are double, with a band set on the outside of the drum, and within, internal expanding brakes.

The body work is of a high order, special attention being given to that part of the work. As ordinarily sent out, the body seats five, but the long wheelbase of 120 inches allows a body which is long enough to seat seven. So, when specified, two extra folding seats will be placed in the tonneau. The painting and trimming are also of a very high order, as would be necessary with a fine body, while the exposed woodwork is right up to snuff, too. The steering wheel and dashboard are of Circassian walnut, and highly polished. The latter is what is known as a clean dash, being encumbered with nothing but the coil box. The painting of the body is optional with the purchaser. The body comes equipped with irons for a top, although this is an extra. A full set of tools and spare parts is included, housed in a neat, yet compact, tool-box, located on the left running board. Complete with gas tank, robe rail, foot rest and other parts usually considered as extras, the car lists at $2,500.

Chase Car Designed for Special Business Uses

NEW UTILITY WAGON FOR WESTERN ROADS

Pursuant to a well-defined policy to give the public what it wants and asks for, the Chase Motor Truck Company, Syracuse, N. Y., is now bringing out a surrey or business wagon, which is in great demand in the West. There, the call is for a combination of business and pleasure, which extends even to the automobile. The new Chase model is patterned along lines which permit it to be used for this purpose, or it may be made into a commercial wagon, pure and simple, by means of a few small changes. In mechanical construction, that is, the chassis, it does not differ radically from other Chase products.

The power is supplied by a three cylinder vertical engine of the two-cycle type. The bore of this is 3¾ inch, which with a stroke of 4 inch allows of a conservative rating of 15 horsepower. The simplicity of this power plant is even more apparent when it is considered that it is air-cooled as well, which means that there is no pump, no water to be renewed frequently, no piping to leak, nor any other sources of trouble.

Simplicity both in number of parts and their operation is heightened by the use of a two speed and reverse planetary transmission, running in a bath of oil. This reduces the control to the point where anyone can operate it.

Even the oiling system shows what an effort has been made to reduce the number of parts to a minimum, as a mechanical oiling device means numerous leads to leak, means a driving mechanism, which adds weight and complications. For this reason, the makers have adopted the self oiling system, in which the oil is introduced into the fuel tank, when the latter is filled. This method brings the lubricant into the cylinders with the fuel, whence the interior is thoroughly lubricated. From the cylinder the oil will drop to the bottom of the crankcase, from which point it will be splashed onto the sides of the case, and flow to the two bearings. Nothing could be simpler.

From the jackshaft, the final drive is by means of double side chains to the rear wheels. These are of large diameter, following modern tendency, in fact, anticipating a few years, the fronts and rears both being 40 inches in diameter. They are equipped with tires of solid rubber, 1⅝ inches in diameter, and spokes of 1¼ inches.

Combined with large wheels, the long wheelbase of 100 inches makes a very easy riding car, while having an unusual amount of road clearance, and the ability to surmount large obstacles, if necessary. A set of full elliptic springs helps to make the car ride easy, while standard tread is adhered to.

The brakes are of the band type and are placed on the rear wheels, the lining being such as to allow easy renewal. Considering the weight is but 1,500 pounds, the axles fitted to this car are ample in size, and their 1¼ inch square section will carry loads far in excess of anything the wagon body would house.

The body ordinarily fitted is of the surrey type, with removable rear seat, the seat in position accommodating four passengers, which the removal and consequent conversion into a runabout reduces to two. A top of the canopy style may be had if desired but at an addition to the regular price of $900. This car is designed to take care of the needs of traveling salesmen and to enable them to cover a large number of towns each day.

For this purpose, the removed rear seat leaves a large space behind, which gives room for salesmen's luggage or sample cases. In this way, not only is the railroad fare saved, but more important than that, much time is saved allowing the same man to cover more towns, with less fatigue. Low operating cost, coupled with the inherent simplicity of mechanism and control, make a car which is ideal for this purpose. Telephone and electric light companies will find this model of great value to their trouble men, while farmers will appreciate it for an errand wagon, and with the added rear seat, for pleasure trips.

ANOTHER WHITE GASOLINE MACHINE

One of the largest buggy manufacturers in the West, the George White Buggy Company, Rock Island, Ill., has established an automobile department and will take up and push this work vigorously. The machine upon which the efforts will be concentrated is of the high wheel type with solid tires. Four models are listed, differing only in the body work.

The motive power is a two-cylinder opposed air cooled four-cycle unit, set crosswise of the steel frame, but attached directly to the latter. The fan flywheel is placed in front and the transmission of power is through a two-speed planetary gear. From this a shaft drive of the approved type, and inclosed in a tube serving as a torsion rod, drives back to the rear axle.

The wheels are of large diameter, 36 front and 38 rear, equipped with 1¾-inch tires of the solid type. In contrast with the usual form of motor buggy, this one is fitted with magneto ignition, the magneto being placed between the two cylinders on top of the crankcase, and is friction driven from the rim of the flywheel.

The steel frame carries at the front and rear a pair of full elliptic springs, these being attached to the frame by means of lugs, which extend upward. The result is to bring the center of gravity as low as is consistent with large road clearance.

SOUTHERN CAR DEMONSTRATORS OUT

BALTIMORE, June 28—Although only engaged in business for a short time, the Carl Spoerer Sons' Company has a number of orders booked for the latest models. These include a 30-horsepower machine, the demonstrator of which type is out, and a 50-60 horsepower car, which will be out in a few weeks. Both models are patterned very closely after the famous German car, the Mercedes. The cars are known by the name of Spoerer.

Dr. C. K. Caruthers' Holsman in Floral Parade

That the well-known high-wheeled Holsman can make its mark in a decorated parade is evidenced by the photograph taken at Pine Bluff, Ark., on the occasion of the Arkansas Travelers' Convention, in that city, June 3.

PIERCE LINE FOR 1910 WILL CONSIST OF SIXES ONLY

BUFFALO, N. Y., June 28—With considerably over one thousand of its six-cylinder cars in successful operation on the road, and the demand for them greater during the past season than the immense new factory could supply, the Pierce-Arrow Motor Car company has announced that for the coming season it will manufacture nothing but six-cylinder cars. A number of considerations have been responsible for this decision, the first of these being the unqualified success that has attended the use of the cars under all conditions of travel by owners. Another is that the indications are that the demand for six-cylinder cars of this make next fall and next year, will be so great as to engage the entire work of the factory to the exclusion of other types.

The coming season will be the fourth in which the Pierce-Arrow Motor Car company has made six-cylinder cars, although it is the first in which it has confined its output to this class. The first six-cylinder cars were placed on the market in the latter part of 1906, when one model was made. One of these cars was entered in the Glidden tour as a non-contestant in order to give it the hardest and most thorough test possible. The car was subjected to much greater hardships than any contesting car, and at the end of the tour showed a mileage of almost double that of the tour itself. By this proof of general efficiency and dependability, the performance paved the way for the adoption of the six-cylinder motor by a large number of motor car users, which has resulted since in their widespread popularity by those who want a car for year-round work under all kinds of road and weather conditions.

The announcement, according to officials of the Pierce-Arrow company, indicates that this company, one of the pioneers in the industry, in making nothing but six-cylinder cars, had found that its experience had cancelled the last doubt in the mind of the public as to the advantages of the six over any other type of motor. For 1910, then, the company will produce three types of chassis, a 36-horsepower, a 48-horsepower, and a 66-horsepower, all of which may have runabout, miniature tonneau, touring, or enclosed bodies fitted.

ELKHART COMPANY BUYS NEW PLANT

ELKHART, IND., June 29—At a meeting of the directors of the Elkhart Motor Car Company, of this city, held last week, it was decided to purchase the new factory building originally erected for the Sterling-Hudson Whip Company, and use it for the manufacture of automobiles. Lack of space in the present factory seriously interferes with prompt fulfillment of orders, and with the new addition the company expects to get out 1,000 cars a year, and employ 400 men.

NATIONAL CAPITAL PLANS FLORAL PARADE

WASHINGTON, D. C., June 28—A floral parade for automobiles and motorcycles is the latest project on foot here. The *Post* has offered prizes aggregating $1,200 in value for the best decorated cars in the several classes, and July 5 is the date selected. The parade will start at half-past four in the afternoon, and the route will be down Pennsylvania avenue to the Peace monument and return, thence to the speedway along the Potomac River, where the judging will be done.

NEW GLIDE SUBURBAN MODEL SHOWS CLASS

PEORIA, ILL., June 28—Increased interest in touring and tours has given body builders much work to do in the line of special bodies, to conform to owner's special requirements. To obviate this, manufacturers are exercising considerable ingenuity to produce high-class bodies which will meet these requirements and thus save the expense and bother of special coach work. A recently catalogued body production comes in this class.

This is the new Suburban model put out by the Bartholomew Company, manufacturers of the Glide. It is a close-coupled body with a place at the rear fitted up for carrying a trunk and two suit cases. This light roadster type of body is fitted to the regular Model G touring chassis, which with a 120-in. wheelbase insures easy and comfortable riding. This same matter is provided for in the springs, these being 40 in. long in front and 58 in. in length for the semi-elliptic rear springs.

This successful new model is well powered with a 4-cylinder vertical motor of 4¾-in. bore by 5-in. stroke. While rated at 45-horsepower, it is said to deliver much more than this. This company was one of the pioneers in the rear axle location for the transmission, which is fast becoming general. It is of the three-speed variety and operates on the selective principle. The tires on Model G are 36 by 4½ in. on all wheels, thus securing interchangeability. In case of extra rapid wear this allows of changing the fronts and rears, so as to lengthen the life of both, the overworked rears being placed in front where the duty is less severe, while the lightly worn fronts are put into service in the back wheels. Although this body is in the nature of a special requirement, the company isn ot making any extra charge for it, but is selling it at the regular Model G price of $2,500, with the option of an Eisemann high-tension type E L magneto at $2.650. The photograph shows the car ready for use.

Suburban Model of the Glide—Latest Product of the Bartholomew Company

WHAT REEVES FOUND IN A ROUND OF FACTORIES

ALFRED REEVES has been making a round of the factories, of course visiting mainly those of the American Motor Car Manufacturers' Association, of which he is the energetic general manager. Being a keen-eyed observer, Mr. Reeves accumulated much information and he supplies a most interesting chapter calling for conscientious reading.

"Of the 200,000 cars planned for the 1910 market," says Mr. Reeves, "165,000 will be of the so-called pleasure variety, 30,000 of the high-wheel buggy class, and some 5,000 utilizing steam and electricity, and also including commercial vehicles. With an average price of about $1,200, and the greatest demand for cars below $1,500, and still no decrease in the demand for high-grade cars, the total business in cars alone will approach $200,000,000.

"Yet with these extraordinary figures on next year's motor vehicle output there is no reason to fear an overproduction, owing to the fact that America's greatest purchasing element in the middle class, has now entered the field together with the farmers, who have been liberal buyers of cars during the year 1909. When it is taken into consideration that there are now 150,000 motor cars in this country and at least that number can be turned out this year, a fair idea can be gained of the present status of the automobile industry.

"It is estimated that this year has seen an oversold condition of about 10 per cent. To many manufacturers it would appear that they could have sold twice as many cars as they made, but in most cases the demand has generally been supplied, and only a small portion of the buying public has been unable to get cars. If next year's record production is to supply the oversold condition of this year the result will be an unsafe business condition. With the great purchasing power of the middle class and of the farmers, there is every reason to believe that the production will be absorbed.

"The importance of the farmers in the buying of automobiles and the influence they will have on road improvement, is more than the average Easterner can understand. There are more than two million farmers in this country, and they have had a big share of prosperity. Kansas, Iowa, and Nebraska have been good automobile States. One maker in Anderson, Ind., told me that 75 per cent. of his $1,250 cars were sold to farmers. The salaried man who believes in good things for his family and the business man who requires quick individual transportation, has made for a greater demand for motor cars, and that situation will be increased very markedly in the coming year of 1910."

Mr. Reeves visited on his Western trip factories in Cleveland, Dayton, and Cincinnati, Ohio; New Castle, Muncie, Indianapolis, Anderson, Mishawaka, and Auburn, Ind.; St. Louis, Mo., and Chicago, Moline, and Peoria, Ill.

On the situation at the factories Mr. Reeves said:

"At Cleveland, Paul Gaeth is making **Gaeth** cars in his usual conservative way, turning out a limited number carefully made. There will be comparatively few changes on the 1910 **Gaeth** as compared with this year's car. Mr. Gaeth is adding to his line a single cylinder commercial wagon for light delivery work.

"At Dayton, O., I was astounded at the size of the Dayton Motor Car Company's plant, which covers three city blocks. A new six-story addition to the factory is being put up that will be 140x110, supplying almost 1,000 square feet more of floor space. I doubt whether any concern in the country makes more of the car than do the **Stoddard-Dayton** people. The company makes its own axles, springs, frames, and aluminum castings. Something like $60,000 worth of new machinery is being installed that will make for a greater production in 1910. The Dayton company is famous for its care of agents, and C. G. Stoddard, the general manager, says the same agent policy would be continued next year. As indicating the size of the plant, I might say that there are 1,600 men employed and that 60 men are engaged in the inspection and testing department.

"The new **Courier** car, selling at $1,000 and marketed by a new $200,000 corporation in Dayton, is practically an offshoot of the Dayton Motor Car Company, for in it are most of its officers and a number of its employees. The car will follow the lines of the **Stoddard-Dayton** car, but on a smaller scale. It will be high-class throughout.

"Another concern in Dayton which is making progress is the **Speedwell** Motor Car Company, which has planned a production of 700 cars for next year. The concern is putting up factory additions, and R. D. Schenck, the president, tells me most of the product has been spoken for by agents.

"Incidentally I was told in Dayton of **a new taximeter** that has many advantages over taximeters now in use. Not alone does it register the distance, amount of fare, and supply similar records, but it turns out a slip just like a cash register, giving the distances, the number of the cab, the time, and the fare. This is given to the patron when he leaves the cab and will be a great source of satisfaction.

"Dayton has been wildly excited over the Wright brothers, and gave a reception such as should be given to men whose names in future will figure with those of Bell, Morse, and Edison. There is an aeroplane club in Dayton with 250 members.

"Cincinnati has been a great city for carriage manufacturers, and at least ten big concerns have announced their intention of turning out motor cars. The majority of them will make cars of the buggy type, but the Jewell Carriage Company is putting out a high-grade four-cylinder car to be known as the **Ohio** that should become a factor in the trade.

"From Cincinnati I visited the giant plant of the **Maxwell-Briscoe** Motor Company at New Castle, Ind. It won't be very long before the name of that town will be changed, for the **Maxwell-Briscoe** people have the biggest factory in town and are factors in the general life. There is a Maxwell amusement park, a Maxwell ball team, a Maxwell gymnasium, and a Maxwell-Briscoe band of forty pieces which is a credit to any community.

"J. B. Meyers, the general superintendent, stated that 1,600 men are now on the pay-roll, and there is great difficulty in housing the help. Houses have been put up at an astonishing rate, but upon my visit there at least 200 men were living with their families in tents.

"The manufacture of **Maxwell** cars is ideal, for the raw material goes in at one end of the factory and comes out a finished product at the shipping platform. Cars are coming through at the rate of forty a day, but the factory is far behind in its orders. A new addition is being put up, 721-310, and another, 721x60. A third floor is also being added to the present factory, all of which is expected to result in a greater production of cars next year.

"At Anderson, Ind., the **Buckeye** Manufacturing Company stated that 75 per cent. of its product this year had been sold to the farmers, and that it is planning for 1,500 cars for next year. The concern says the agricultural people have more money than at any other time in their history and look upon the automobile, not as a luxury, but as a necessity for individual transportation. The friction drive **Lambert** has appealed to them strongly owing to its simplicity. The same design of car will be made next year.

"Claude E. Cox, who designed the Overland, is now chief engineer of the **Inter-State** Automobile Company at Muncie, Ind., which plans a production of 2,500 cars for next year. The company now has a building 440x140, and will build an addition equally as large. The car is of 35-horsepower. F. E. Hart, a successful business man of Muncie, is president of the **Inter-State** Company, and D. W. Henry is sales manager.

"Indianapolis manufacturers accepted an invitation of H. O. Smith, the A. M. C. M. A. chairman, for a luncheon at the Columbia Club on my visit to that city. In attendance were John N. Willys, **Overland** and **Marion**; Walter E. Marmon, **Marmon**; V. A. Longaker, **American**; A. C. Newby, **National**; Carl Fisher, **Empire**; Herbert Rice, **Waverly**, and H. O. Smith, **Premier**. We had an interesting discussion of automobile matters generally, and the next day I visited the various plants.

"One of the sensations in the town has been the advancement of the **Overland** under the leadership of John N. Willys. The company now has five factories working to get out the cars promptly and keep agents supplied. It will have two new buildings near the present Overland factory, each 368x80, two stories high. A production of 10,000 **Overlands** is planned for next year and 1,000 **Marions**. Overlands will be turned out at the new Pope-Toledo plant at Toledo, as well as in Indianapolis. There will be three models of Overlands next year.

"Mr. Willys has gone to Europe to look over trade conditions there, but will return early in September. The sales end of the business is now being looked after by F. A. Barker, formerly with the Dayton Motor Car Company. There are now 1,200 men working for the Overland Company at Indianapolis and 400 on the pay roll at Toledo. The company has been unusually successful.

"That more and more concerns are making their own parts is evidenced by what I saw in the **American** factory, which I visited with Mr. Longaker. Almost the entire car is being made under one roof, instead of depending upon parts makers for supplies. The **American Traveler**, with its underslung body, is growing more and more in favor, and the production is being increased to keep up with the demand.

"Howard Marmon's genius in motor car construction is evidenced in the small **Marmon** of this year, which has met with such favor and which will be continued with comparatively few changes for 1910. The motor is of 32 horsepower and while it is of the small type now so popular, the material and construction throughout is of highest grade. The company will have two machines in the Glidden Tour.

"The **Premier** plant is working nights, for H. O. Smith is a firm believer in caring for agents by giving them cars when the demand from the public is strongest. The **Premier** has had an unusually successful year in contests, and three of them will be entered in the Glidden Tour, besides the Premier that will act as an official car. Additions will be made to the plant next year, although Mr. Smith is inclined to grow conservatively rather than with a rush.

"A. C. Newby, at the **National** plant, showed me plans for a new addition that will supply 40,000 square feet of space. The present line will be continued next year, with some slight changes, the cars having made good in every way. There will be a small four and a big four, and a little six and a big six.

"The **Empire** is the latest car in the field, being the production of R. H. Hassler, backed by a company in which A. C. Newby and Carl Fisher are interested. The old Mohawk Cycle Works factory on the outskirts of Indianapolis has been taken and a thousand cars will be put through for 1910. The motor is 3½x4, cast *en bloc*. A runabout body is fitted, 32x3½ tires, and the price will be $800.

"St. Louis is a busy automobile town just now, the three companies there being the **Moon** Motor Car Company, **St. Louis** Car Company and **Dorris** Motor Car Company.

"Next year the horsepower of the $3,000 **Moon** car will be increased from 35 to 40, and in addition the company will make a $1,500 car rated at about 30 horsepower. The company has had an unusually good Western business, incidentally selling more cars in the State of Texas than in any other section of the country.

"A new company will take over the St. Louis Car Company, which will discontinue the American Mors to make a new car of American design, called the Standard Six, with a motor of 50 horsepower. The general manager is H. E. Walton.

"The **Dorris** Motor Car Company continues to turn out high-grade cars, and each year has seen a decided increase in its business. Manager Krenning is a believer in the one-chassis idea, and the 1910 car will be a refinement of the same model which it has used for the past three years and which has proven so satisfactory. It is of 30 horsepower and sells at $2,500.

"At Peoria I noted a decided increase in the size of the factory of the Bartholomew Company, makers of the **Glide**. The plant will be aided in its production next year by a new factory, plans being under way for the taking over of the old St. Louis Carriage Company plant. Mr. Bartholomew, besides his interest in the Bartholomew Company with his son, A. Y. Bartholomew, and G. G. Godfrey, is the president of the Avery Company, one of the largest manufacturers of agricultural machinery in the country. The Avery plant is a revelation in the manufacturing line, and many of its methods are being incorporated in the automobile plant. The car next year will be a refinement of this year's 45-horsepower, with a motor 4¾x5, the point being made that the satisfactory car of this year required little change.

"In Chicago I visited the **Holsman** Automobile Company. This company is far and away the leader in the motor buggy business, and its production is constantly on the increase. It has had a phenomenal year and is making great preparations for 1910.

"At Chicago I was told that the **International** Harvester Company is planning to produce 10,000 buggies next year, while Sears, Roebuck & Company, the mail-order house, gave an order recently for 10,000 axles to be used on motor buggies for 1910.

"Moline, Ill., is getting to be one of the leading automobile cities of the country, having three factories in operation. At the **Midland** plant they were preparing a car for the Glidden Tour, and making arrangements for next year's trade. A. E. Montgomery stated that the company had been favored with an excellent Southern trade, particularly in Texas, which seems to be coming to the front as an automobile State.

"At the plant of the **Velie** Motor Vehicle Company I found a factory 80x220, four stories high, with an army of workmen building an addition that will double the present capacity. The present car now will be continued next year.

"At the **Moline** Automobile Company's plant W. H. VanDerVoort stated that the last of the product would be shipped from the factory by July 1 and that work is now under way on the 1910 models. He plans to continue his care of agents, supplying cars instead of promises, and believes strongly in supplying a sufficient number of cars to enable an agent to make a profit on his year's business. Additional help is being taken on and more room added for manufacturing purposes, which will permit a 50 per cent. increase in production next year. Three roadsters will be entered in the Glidden Tour for the Hower trophy and they will not be of the untried sort, for they were on the road a month ago and are being put through a series of severe tests. Besides their high-class four-cylinder car, the company makes a $1,500 four-cylinder machine for the country trade.

"The **American Simplex** car, made at Mishawaka, Ind., is the only high-powered two-cycle car built in this country. It is equipped with a motor of 50 horsepower at 900 revolutions. A feature of the car that Messrs. Graham & Gulick showed me was a carbureter of their own design which vastly reduced the gasoline consumption, often a point made in cars of the two-cycle type. The company has a well-equipped factory and is building an addition that will permit about a 50 per cent. increase in the production for 1910. One **American Simplex** will compete in the Glidden Tour.

"To show his faith in the reliability and continuous running qualities of the buggy type of machine, W. H. McIntyre, the manufacturer of the **McIntyre** car at Auburn, Ind., has entered a machine in the Glidden Tour. It is expected by continuous running to make the same average speed as cars of greater power. It will be the only one of its type in the tour. It is equipped with a two-cylinder, air-cooled motor and is shod with solid tires. Incidentally, Mr. McIntyre has been a resident of Auburn for forty years, owns the daily paper there, and is interested in a number of its industries. His carriage factory turns out 30,000 to 40,000 horse-drawn vehicles annually.

"No factory that I visited is more modern than the plant of the **Mora** Motor Car Company, at Newark, N. Y. It is light and clean, with high ceilings, and Mr. Mora insists it all helps the men to turn out good work. All the 1909 cars will be out by July 10 and will be delivered immediately to customers through the agents. Work is now under way on the 1910 product, which will be new in several features, although carrying most of the features that have made the **Mora** car so successful during the past two years. The horsepower of the four-cylinder car will be increased from 24 to 35. Among the other features is the casting of a ledge on the engine base reaching to the radiator, which, combined with the original **Mora** under-pan idea, makes a complete covering of the under part of the machine, insuring a clean motor and clean working parts.

"S. H. Mora, owing to his long experience as sales manager of the Kodak Company, thoroughly understands the handling of agents, and appreciates the necessity of keeping them supplied with cars at a time when the cars are in the greatest demand. His arrangement with agents is such that almost all of them receive an allotment of cars sufficient to make a substantial profit.

"Great preparations for next year in the way of additional buildings and the demand for additional help, to say nothing of the betterment of cars, both in material and construction, coupled with the reports of agents asking for 1910 cars and territory, enables even the poorest prophet to declare for a great selling year in 1910."

DOWAGIAC MOTOR WORKS OFFICERS KILLED

DOWAGIAC, MICH., June 28—F. A. Lake and Leon R. Lyle, both of Dowagiac, Mich., who were killed in the South Shore wreck near Chesterton, Ind., when eleven people lost their lives, were president and secretary, respectively, of the Dowagiac Motor Works. They were homeward bound from the automobile races at Crown Point, Ind.

MRS. "MAXWELL" RAMSEY REACHES OMAHA

OMAHA, NEB., June 28—Nearly half way across the continent, after a run of 1,700 miles, Mrs. Alice R. Ramsey and her party of women autoists, who are traveling from New York to San Francisco in a Maxwell touring car, reached this city yesterday, and this morning resumed their journey towards the Pacific. So far the trip has proven Mrs. Ramsey's contention, that in the right car a woman can make the trip without trouble. Several times the wheels of her Maxwell have gone hub deep into the mud, but each time it pulled out, and once, after having left Chicago, it not only got out of a particularly bad spot alone, but pulled a big, six-cylinder car out, too. Excepting for this, the trip has been without incident, though there have been plenty of amusing incidents from the time the party left New York, June 9. In every way it has been a most successful trip, but one blow-out necessitating a tire change. On account of the many receptions accorded the women, the mileage has been a bit smaller than could have been made. In almost every town and city between New York and Omaha the car and party have been given a great reception, while in Chicago they were met outside of the city limits by a dozen or more cars and escorted in. When they started for Clinton early in the week, the first stop on the run to Omaha, more than 40 cars drove out 50 miles with the tourists, and it was a happy party that left the city. So far, the trip has been thoroughly enjoyable in every way, which, of course, is partly due to the fact that the big touring car has gone from 125 to 191 miles every day, those figures being the lowest and highest recorded.

MAXWELL BENEFIT SOCIETY

Employees of the New Castle, Ind., factory of the Maxwell-Briscoe Motor Company have recently perfected a social and athletic organization and benefit association, which they call the "New Castle Gymnasium." They assess themselves ten cents each per week, and thus have a sick benefit and insurance feature. The company has co-operated with the men and has furnished a very complete gymnasium, reading and billiard rooms, etc., and out of the 2200 people employed in that plant, about 1600 are members of the organization. Under its auspices are a baseball team and the Maxwell-Briscoe concert band of 30 pieces, and during the winter there are classes in mechanical drawing, metallurgy, and other subjects pertaining to automobiles. According to Benjamin Briscoe, president and general manager of the Maxwell-Briscoe Company, this is the largest and most completely organized employees' association in the auto industry.

Overland "Thirty" That Carried a Notable Four

At the wheel on a recent trip over Long Island roads was A. E. Schwartz, foreign representative American Motor Car Manufacturers' Association; in same seat, L. M. Bradley, advertising manager A. M. C. M. A.; in rear seat, A. J. Sticker, of Frank Presbrey Company, and the well-known automobile writer, Arthur N. Jervis.

Good Roads Advocate Klouse and His Rambler

RAMBLER ASSISTS IN GOOD ROADS WORK

CHARLOTTE, N. C., June 28—In an energetic campaign now being conducted throughout the South in behalf of good roads, newspapers, automobile manufacturers, and automobile owners are enthusiastically co-operating. The campaign has now reached a point where the desire for good roads has become almost a mania, and autoists in all parts of the South are making tours to educate the users of the road in the importance of better public highways.

Joseph Klouse, of this city, has just made a trip of 3000 miles in a Rambler, in which he visited many of the important cities in the South, distributed literature along the way in behalf of good roads, and aroused much interest in the movement. The Rambler driven by Mr. Klouse has traveled over 18,000 miles, and it finished one run of 250 miles, from Charlotte, N. C., to Atlanta, in 21 hours and 30 minutes. Mr. Klouse represents the Charlotte *Daily Observer* in the New York *Herald*-Atlanta *Journal* good roads promotion.

FRANKLIN PUPILS LEARN RAPIDLY

SYRACUSE, N. Y., June 29—Tangible results of instruction in the repairmen's course maintained in the automobile school at the factory of the H. H. Franklin Manufacturing Company are in evidence in the shape of two automobiles assembled from raw stock by the pupils. It took three members of the class two weeks to construct the two cars, when the work was passed upon by the testers, just as are cars in the regular course of manufacture. The class has twenty-six members, under supervision of I. O. Hoffman, formerly an instructor in Syracuse University. The course is one of twenty-six weeks, providing both theory and practice, most of the time being spent in practical work.

Class Receiving Instruction in Franklin School

DOW RIMS FOR LARGE TIRE CONCERNS

An announcement of much interest to the trade at large is the adoption of the Dow Remountable rim by the Hartford Rubber Works Company, Hartford, Conn., and the G & J Tire Company, Indianapolis, Ind. In making this announcement, the two tire companies feel that they are offering to the public a rim which can be recommended, and the use of which is spreading very rapidly. The rims may now be had with both the regular Clincher and the Universal Q. D. form.

Under license to the Dow patents, the rims are now being made by the Weston-Mott Company, Flint, Mich., this firm being one of the largest in the country as to size and excellence.

In construction, the Dow rims are extremely simple; there are no loose pieces to be lost, no nuts or bolts to be loosened. The act of putting a rim on or taking one off is very easy, consisting of a few turns of a wrench, and the removal of the tire and rim. This wrench through the medium of a rack attached to the rim rotates the same, which slides wedges over one another, one set being attached to the felloe and another to the rim. As these wedges form the attachment of the rim to the felloe, this rotation loosens or tightens the contact according to its direction. These features have made it easy for amateurs to use and indirectly resulted in the above announcement.

Great Western Car After 800-Mile Mud Battle

This car, which is manufactured by the Model Automobile Company, Peru, Ind., recently made a hard trip through Illinois and Indiana, traveling 800 miles through mud and rain. The bundle on the luggage rack was a brand new suit case at the beginning of the trip, but after the pounding it went through it was in shreds.

REPUBLIC TIRES PROVE EFFICIENCY

Automobile accidents nowadays are limited almost entirely to peculiar and unheard-of mishaps. One of the oddest occurred to Mr. Pratt of the Republic Rubber Company recently. He was driving in New Rochelle, N. Y., when the brass shutter in his carbureter broke off, producing the effect of a wide open throttle. The engine immediately began to race, and while the driver was trying to get control, the car began to travel at top speed. It did not occur to the driver to throw out his clutch for a few moments, as he expected at any instant that the car would respond to the throttle control.

Meanwhile several sharp curves were passed and there was imminent danger of skidding. The car was equipped with Republic staggard tread tires, which were given an unusual test of their anti-skid qualities, and proved remarkably effective so that the expected side-slip never occurred, the tires gripping the road in a most comforting and satisfying way. The car was soon stopped, the trouble located and remedied.

Newark, N. J.—The Imperial Garage has been opened on Belleville avenue by F. W. Briggs, who was formerly connected with J. M. Quimby & Company.

SOME SELECTED AUTOMOBILE PATENTS

Issue of June 15

924,634. Explosion Engine—Richard D. Cody, Winona, Minn. Filed Feb. 23, 1904.

924,639. Governor for Explosion Engines—Hsrry M. Cramer, Lansing, Mich. Filed April 12, 1907.

924,640. Explosion Engine—Harry M. Cramer, Lansing, Mich. Filed April 20, 1908.

924,673. Carbureter—James B. Knickerbocker, Indianapolis, Ind. Filed Nov. 21, 1907.

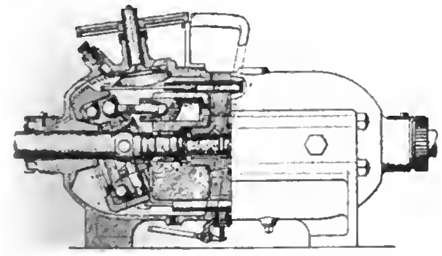
924,715. Self-Measuring Oil Pump—Flavius J. Young, Fort Wayne, Ind. Filed Oct. 23, 1908.

924,724. Spring Wheel—John W. Benson, North Wayne, Me. Filed July 7, 1908.

924,757. Steering Mechanism for Self-Propelled Vehicles—Rodolphus Fuller, Detroit, Mich. Filed Feb. 6, 1908.

924,787. Variable Speed Transmission Device—Reynold Janney, New York, N. Y. Filed July 9, 1906.

This is a combination of oscillating crank engine with speed transmission. The pistons travel back and forth in a housing and in so doing operate a rotary oscillating crank. The admission of fuel to the odd number of pistons is controllable, and, of course, variable. In this manner the speed of the engine may be varied at will. The drive is from the rotating crank by means of a gear, the shaft of which projects through the crankcase. On the extremity of this shaft is placed a gear, either of the spur type, or a sprocket, from which the drive is transmitted. As shown in the patent office sketch, the device is apparently double ended, there being as many pistons at the right hand end as at the left.

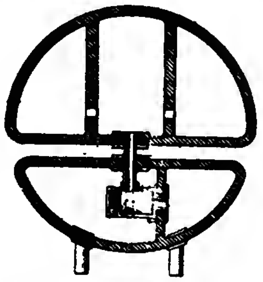


Janney Oscillating Crank Engine

924,806. Antiskidding Attachment for Wheel Tires—George A. Lyon, Philadelphia, Pa. Filed March 18, 1907.

924,812. Pneumatic Tire—Daniel McArthur, Jersey City, N. J. Filed April 15, 1908.

In his tire, McArthur has a series of tire compartments, divided one from the other by means of partition walls, which in use would be perpendicular to the road surface and thus, would take part of the load. These surface partitions are connected to an air conduit in the base of the tire by means of a series of individual valves. In case of the puncture of any one surface section the valve closes so that no more air may enter.

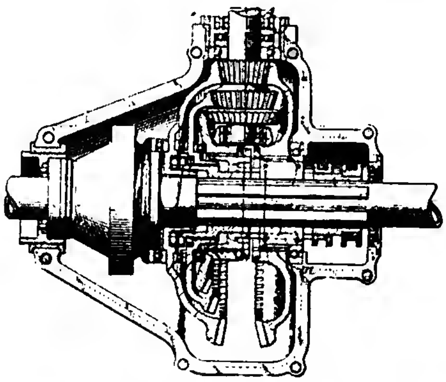


McArthur Compartment Tire

924,863. Spark-Ignition Device for Explosive Engines—James A. Whitton, Los Angeles, Cal. Filed Nov. 26, 1907.

924,889. Variable Speed Gearing—Gustave Chedru, Buffalo, N. Y. Filed July 16, 1907.

A new idea on the part of the Thomas engineer has for its basis a series of bevel gears and pinions, clutched up to the rear axle by means of individual clutches. Throwing the clutch for any one of the gears connects it to the axle, and thus transmits the drive from the engine. In this manner three speeds and a reverse are provided in a very small compass. Although nothing is said about the control, it is easily apparent that this could be arranged to operate upon the now popular selective principle, in which case an excellent and very compact final drive will have been obtained.

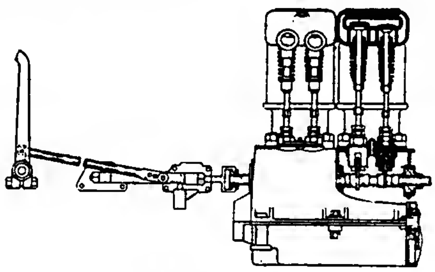


New Thomas Rear Axle Transmission

924,913. Recoil Check—Frederick J. Mellen and Burton A. Edwards, Beloit, Wis. Filed Nov. 11, 1908.

Issue of June 22, 1909

925,528. Pneumatic Brake for Motor-Vehicles—Ernest E. Sweet, Detroit, Mich. Filed Jan. 11, 1908.



Cadillac Braking Device

A device for braking the car by drawing the exhaust cam out from under the valve, when the exhaust gases can not leave the cylinder, and the piston continues to compress them, over and over, this acting to retard the forward motion of the car.

925,536. Vehicle-Wheel Bearing Mechanism—Clarence F. Umholtz, Bristol, Va. Filed Mar. 23, 1908.

925,543. Vehicle-Brake—Joseph H. Wesson, Springfield, Mass. Filed June 30, 1908.

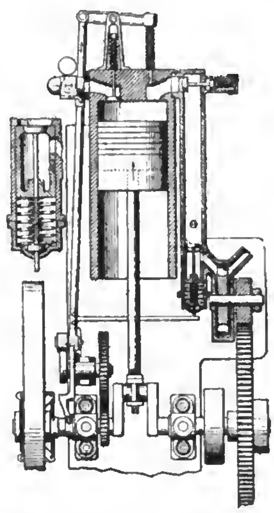
925,560. Felly for Wheels with Pneumatic Tires—Theodor Bruckner, Vienna, Austria-Hungary. Filed Nov. 9, 1906.

925,579. Running Gear for Vehicles—Martin W. Heyenga, Chicago, Ill. Filed April 24, 1908.

925,580. Tire—Charles H. Keiffer, Akron, Ohio. Filed Jan. 25, 1909.

925,766. Internal Combustion Engine — Leander E. Fish, Los Angeles, Cal. Filed Feb. 21, 1908.

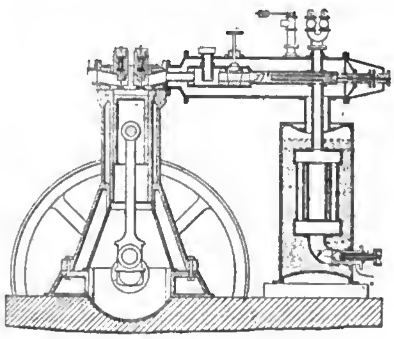
Fish has an idea here of doing away with the valve operating mechanism of one valve, and also utilizing an automatic inlet valve, with all of the advantages of the mechanical valve. This effect is secured by having a mechanical agitator, which at the same time mixes the gases and regulates the amount allowed to enter. These mixed and measured gases enter through a valve operated from the exhaust push rod into a vertical passage. From this latter the entrance to the combustion chamber is by means of an automatic valve. While the drawing makes the engine look complicated it may possess much merit.



Engine Simplification by Fish

925,845. Method of Utilizing Heat of Combustion and Steam Power in Prime Movers—Theodor Schtscherbakoff, Moscow, Russia. Filed Sept. 10, 1904.

The Russian, with the unpronounceable name, intends to utilize the heat ordinarily wasted in the exhaust by passing it first through a muffler, after which it goes to a heating chamber. In the latter, it is made to heat water, which latter the inventor proposes to use in a nearby steam boiler. The idea is to do away with the ordinary feed water heater, probably, but the fault in the whole scheme is that where gas engines are used for power, steam is seldom also used. The opposite of this also holds true, so that there seems to be very little field for a device like this.



Method of Utilizing Waste Heat

925,908. Wheel for Road Vehicles—James Henderson, Burton, England. Filed Aug. 17, 1907.

925,930. Wheel Tire—Joshua D. Marvil, Laurel, Del. Filed Sept. 11, 1908.

Midland Car Makes Plowing a Fine Art

Recently at the factory of the Midland Motor Company, Moline, Ill., additions necessitated the plowing of a large tract of land. Horses being at a discount around an automobile factory, a car was hitched up to a plow and with a man to drive and another to guide the plow, the land was plowed in about one-fourth of the time it would have taken horses to do it.

Grease Lubrication Under Heavy Bearing Pressures—In automobiles abnormal bearing pressures are liable to occur, which severely test the quality of the lubricant employed. In some tests of Keystone grease, manufactured by the Keystone Lubricating Company, of Philadelphia, recently made by a competent authority, this automobile lubricant showed remarkable performance under heavy bearing pressures. The Olsen testing machine was employed, and the pressure was increased by steps of 86.2 pounds per square inch up to the high maximum pressure of 431 pounds, a full sixty-minute run being made at each pressure. During the entire run at each pressure the lubricant maintained true fluid friction between journal and bearing and withstood the temperature rise without a sign of any disintegration. This result is stated by the company to be due to the permanent consistency of Keystone grease under great increase of bearing pressure and temperature—it does not squeeze out of the bearing nor soften by heat and run away from between the surfaces requiring lubrication at the very time it is most needed.

Riggs Becomes an Oregonian—The West gets a lot of the good ones in the automobile business. Perhaps it is the echo of Horace Greeley or the clink of the big round silver simolean that draws the regulars of the trade to the far side of the Rockies, where the people raise enough prunes, oranges and canned salmon to raise the price of good automobiles and thereafter raise dust on all highways anent the Pacific ocean. Frank C. Riggs is the latest—Riggs, till now assistant sales manager of the Packard Motor Car Company, erstwhile vice-president of the Fisk Rubber Company, and one of the old friends back in the days of "Yellow Fellows" and other bicycles that made life worth living while waiting for automobiles. Mr. Riggs will be in Portland, Ore., soon after July 1. He will be dealer for "Three P's"—the Packard "Thirty," Packard "Eighteen" and Packard truck. Mr. Riggs will have temporary headquarters at the Hotel Portland, but will establish a permanent store without delay.

Enlarged Factory for Hartford Shock Absorbers—"We have found it necessary," says Edward V. Hartford, president of the Hartford Suspension Company, "to increase our manufacturing facilities at Jersey City. For the past six months we have been so swamped with orders not only from automobile manufacturers, who use our suspensions as standard equipment, but from individual users as well, that we have arranged to duplicate our already large factory. With these increased manufacturing facilities we expect to catch up on past orders and in three weeks to a month's time hope to be able to deliver promptly."

Winton Branch and Road Men to Meet—Sales Manager Churchill has called a convention of Winton branch managers and road men to be held at the Winton factory in Cleveland during the week of June 28. Final reports in the $2,500 Winton Six upkeep contest are expected sufficiently early for the judges to meet in Cleveland about July 10 and make the awards. Indications are that the winning record of last year—11,683 miles at a repair expense of $12—will be beaten by this year's winner. The upkeep contest is an annual Winton fixture and will, of course, be continued.

Stearns Sure to Get Parts—The F. B. Stearns Company, of Cleveland, has adopted a new plan of insuring its securing prompt delivery of the materials and parts which go into the Stearns product. For next year an expert will travel all over the country to call on firms from whom the Stearns company purchases, such as magneto, bearing and other manufacturers, and it will be his duty to see that adequate steps have been taken to give the Stearns concern its supplies on schedule time. If there are any methods by which these can be hurried along he will suggest them.

Colwell's Play Meets with Success—M. Worth Colwell, of the Wagner-Field Company—advertising, not theatrical—has produced his vaudeville sketch in Brooklyn and the play was well received. It is entitled "The Child from Pittsburg" and was written jointly by Colwell and Alan Brooks. The latter, who was "Bub" Hicks in Ade's "College Widow," and later a comedian in "A Stubborn Cinderella," plays the title rôle, and Jeanette Despres, who was with Hitchcock in "A Yankee Tourist," is the leading woman.

Big Prize Money for Cobe Winner—Louis Chevrolet and his team-mates, Robert Burman and Louis Strang, have been presented with a purse of $10,000, to be divided equally among them, for their performances in the races on the Crown Point course. Chevrolet won the Cobe cup for big cars with his Buick, and all three men took part in both events. This reward is in addition, of course, to their regular salaries and to the sums which Chevrolet received from certain manufacturers of accessories.

F & S Bearings and U & H magneto on Prince Henry Winners—The J. S. Bretz Company, New York, has been advised by cable that the F & S bearings, which it imports, were on all of the first twelve cars in the Prince Henry contest except the seventh, and that these bearings were also used by the winner of the speed test. Another cablegram states that the U & H magneto was on the Opel car which won the contest and that the same make of magneto was used by the first two cars in the speed trials.

Covert to Erect Big Shops—The Covert Motor Vehicle Company has purchased a large block of land in Lockport, N. Y., between Grand and Green streets, near Lock street, on which to build a new factory. The present plant is not large enough, and the first building of the new one will be of brick, 130 feet long and 50 wide, two stories high. This allows space for other structures.

New York Tradesmen Form Baseball League—The baseball fever is epidemic with the New York tradesmen, evidenced by the New York Automobile Trade Baseball Association, which comprises the following teams: Packard, L. H. Wessels; Thomas, W. A. Woods; Pierce, Walter Wunder; Studebaker, James H. Barry; Diamond Rubber Co., C. G. Studebaker; Republic Rubber Co., George C. Kloss.

Vanguard Company to Enlarge—The Vanguard Manufacturing Co., Joliet, Ill., maker of spark plugs and wind shields, has had plans completed for a new building which will be 60 by 250 feet in size, one story high, constructed of brick and concrete. This will more than double the present output and will give facilities for operating a brass foundry and adding specialties to those now made.

Chalmers Winner Had Continental Rims—The use of demountable rims, which are positive in their action, both as to ease of replacing and as to security when fastened, is necessary in automobile races. The winning Chalmers-Detroit car in the Indiana trophy race was equipped with Continental demountable rims and was able to make tire changes in record time.

Lexington Company Will Increase Capital—The Lexington Motor Car Company, of Lexington, Ky., is about to double its capitalization, raising it from $25,000 to $50,000, in order to enlarge the factory facilities. The cars have been in great demand and it is now stated that orders are on the books which will take up the entire output of five or six cars a week for two months.

Dorris to Increase Output—The Dorris Motor Car Company, St. Louis, has purchased ground at Sarah street and Forest Park, 185 by 200 feet on each, respectively, on which to enlarge its present factory. The new building will be of brick, three stories high, and will cost $60,000. The output of the Dorris cars will be considerably increased.

Last 1909 Winton Shipped—The last 1909 Winton Six has been sold and shipped from the factory in Cleveland, marking the close of the most successful season in the history of the Winton company. The company's products for 1910 will be announced July 10.

IN AND ABOUT THE AGENCIES

Pullman Makers Make Agency Contracts—The York Motor Car Company, manufacturer of Pullman automobiles, announces closing with the following concerns of agency contracts for 1910: New York, Cimiotti Brothers; Boston, Crown Motor Car Company; Buffalo, Meyer Carriage & Auto Company; Baltimore, Shaffer Manufacturing Company; Minneapolis, Minn., Victoria Motor Car Company; Oklahoma City, Okla., O. G. Lee.

White Company Opens Washington Branch—The White business in Washington, D. C., has grown to such proportions, due in no small measure to the patronage of President Taft, that it has become necessary to establish a district branch office of the White Company in that city. The new branch is located at 1124 Connecticut avenue, in charge of F. I. Chichester, and is under the control of the Eastern branch in New York.

Renault Extends Trade in West—Renault Freres' selling branch in New York announces that it has arranged with F. A. Bennet to handle the Renault cars in Oregon, Washington and Idaho, and with the Colburn Automobile Company of Denver for the State of Colorado. The new cars, with reinforced axles and springs, and extra high clearance, have proven very successful on the Western roads.

Pierce-Arrow, Pittsburgh—Headquarters have been secured by the McCurdy-May Company, new agents in Pittsburgh for the Pierce-Arrow Motor Car Company. Buffalo, N. Y. The building is located at Baum street and Euclid avenue, East End. Robert R. McCurdy, for six years with the Banker Brothers Co., will be manager of the new company.

Two Diamond Branches Under One Manager—The Diamond Rubber Company states that although for more than a year George J. Bradley has been manager of the company's Detroit establishment, he is still manager of the Cleveland branch as well. Division of his time between the two points has led to some confusion.

Great Western Agents Appointed—The Model Automobile Company, manufacturer of the Great Western automobiles, announces the following agencies: Omaha, Neb., F. A. Reynolds; Scribner, Neb., John Borcher; Wadena, Ind., C. R. McNown; Nicholasville, Ky., C. A. Kenney.

Diamond to Open Atlanta Branch—The Diamond Rubber Company has arranged to open a direct factory branch in Atlanta, Ga., at 48 Auburn avenue, about the middle of August, from which to handle the growing Southern trade.

Miller Will Open Hartford Branch—Charles E. Miller, of New York, it is reported, will open a branch house for the sale of automobile supplies in Hartford, Conn.

Brown, Thomson & Company, Hartford, Conn., have taken the agency for Stevens-Duryea and Cadillac automobiles in place of the Packard.

RECENT BUSINESS CHANGES

Baltimore—The local agent for the Oakland, Reo and Hupmobile, Little Joe Wiesenfeld, has secured the services of David Asher, a former New Yorker. O. G. Hoff, until recently with the local branch of the Olds Motor Works, has taken a position with Leo Schaab, who conducts the Baltimore agencies for Stoddard-Dayton and Renault cars.

PERSONAL TRADE MENTION

A. W. Hall, of Cleveland, formerly a member of the firm of Hall Bros., Cartercar and Plymouth truck agents, has left the above concern, going to Plymouth, O., to take entire charge of the Plymouth factory. Hall Bros. has become The V. R. Hall Automobile Co., continuing with the same line of machines as before.

Ronald E. Maude, representative of the Deasy Motor Car Manufacturing Company, Ltd., of England, is now in this country with the purpose of introducing the product here. The Deasy company makes three types of cars, all with four cylinders.

Maurice Bernin, the former Renault racing driver, will shortly go to New Orleans, where he will start a Renault Taxicab Company and also have the agency for the Renault cars.

T. Dudley Riggs, representative in Hartford, Conn., for the Simplex automobiles, has returned to his old home, Baltimore, and will enter the automobile business there.

TAXICABS AND TRANSIT

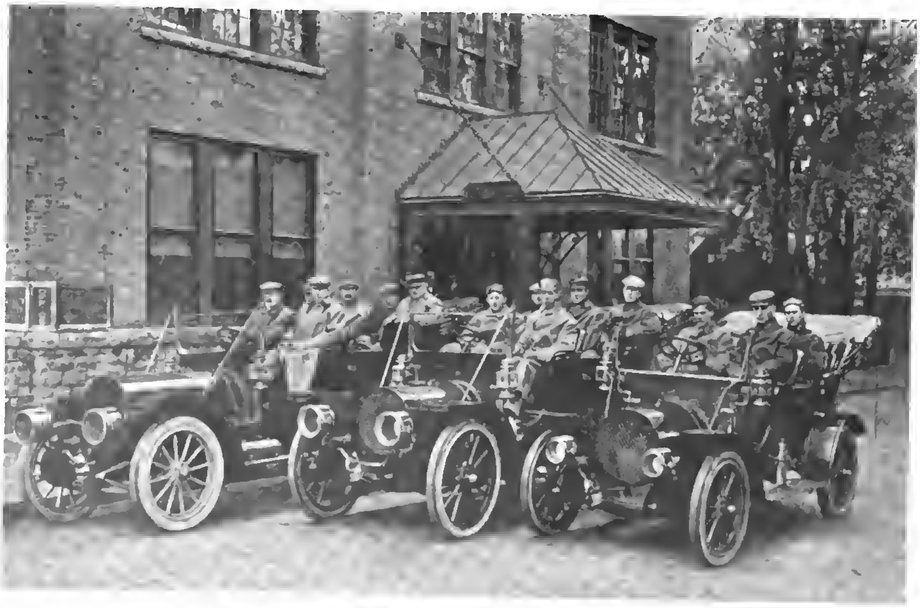
Taxicab Ordinance Changed—After several months of backing and filling, the New York City Board of Aldermen finally amended the taxicab ordinance so as to limit the charges to 30 cents for the first half mile on two-seated cabs and 40 cents for four-seaters. As there are practically none of the former in the city, this amounts to lowering the present universal rate of 50 cents. The ordinance also provides for frequent inspection and correction of taximeters. It was signed by the Mayor and will go into effect about October 1.

HOW WINNERS LUBRICATED

Matson, Chalmers-Detroit winner of the Indiana trophy, and Chevrolet, Buick winner of the Cobe cup at Crown Point, Ind., June 18 and 19, chose for their lubrication Harris oils. The makers are much elated at the double victory.

TESTED NEW MODELS HIMSELF

It usually happens that the work of trying out the new models for an approaching season is left to a paid tester, to whom the job is like any other, all in the day's work. Not so at the Franklin factory, when three of the newer cars for 1910 had been completed; these were taken in hand by President H. H. Franklin himself, with a specially organized party of factory heads, and personally driving one of the three. They were subjected to a five-day tour, in which an average per day of 165 miles was covered, the total being 823 miles. This was over roads, through mountain climbs, and wherever hard going could be found in the general direction in which the party was traveling. The roads, hills and speed tests put up to the latest product of the big Syracuse factory were fully equal to anything which will be met on this year's Glidden Tour. The main course was from Syracuse to Boston, with an extensive detour through the Catskills. The largest car was the seven-passenger forty-two horsepower machine driven by Mr. Franklin. The other two were a twenty-eight horsepower touring car carrying five and driven by Arthur Holmes, and a four-passenger car of eighteen horsepower, driven by R. A. Vail. The whole party included President Franklin, Vice-president Giles H. Stilwell, Secretary-Treasurer F. A. Barton, Sales Manager F. R. Bump, Advertising Manager J. E. Walker, Sundry Sales Manager J. G. Barker, Traffic Manager Herbert Hess, Superintendent F. J Haynes, Chief Engineer John Wilkinson, Assistant Engineer Arthur Holmes, Engineer R. A. Vail, Engineer R. W. Coughtry and Charles Slingerland.



The Franklin Testing Party Starting from the Factory with the 1910 Models

RECENT PUBLICATIONS

Peerless Motor Car Company, Cleveland—An announcement of the 1910 models of this prominent firm includes no radical changes, but only the incorporation of new features, these being rather on the infinitessimal order, and one new model, a 20-horsepower town car. The latter is equipped with a four-cylinder 4x4 5-8 motor, for which the A. L. A. M. rating would be 27, but which the makers prefer to rate at 20. This will be known as Model 29, and will be equipped with but two body styles, limousine and landaulet. For both, the wheelbase will be 113 inches, and the wheels 32 inches in diameter with 3 1-2-inch tires all around. The minor changes in the standard cars include more stiffening ribs on the one-piece crankcase, a new carbureter, larger diameter clutch on the "six," the advanced position of the transmission case, which allows a more comfortable location of the levers, the lengthening of the propeller shaft which accompanies the movement of the transmission, with consequent decrease in the angle of the same. In addition, the springs are lengthened, the fronts by two inches and the rear sides by four inches. This latter change should make a very easy riding car, for the springs of last season were already long.

Societe Anonyme Des Automobiles "Unic," Puteaux, Seine—As a sample of the better class of French car manufacturer's trade catalogues, this is very interesting. The artistic and the practical are combined excellently, there being a surfeit of neither one. The press work, unusually difficult with the three colors used, is very well done. Five chassis are built, or rather five engines are used, the number of chassis being far in excess of this. These five motors are placed in as many chassis for runabouts and touring cars, while four of them are also used for commercial vehicles. Of the latter four, two may be had fitted for cab use or light delivery wagons. Two more are put into special chassis for truck, omnibus, and other heavy work of a similar nature. The five engines are: 10-horsepower, two cylinders, 102 by 110; 12-horsepower, four cylinders, 75 by 110; 16-horsepower, 87 by 110; four cylinder, 24-horsepower, 102 by 116; and a "six," 25-horsepower, 85 by 120, the latter being used for touring cars only. A series of very interesting marginal cuts show the various engines, most of the parts of the same, views of the transmissions, and other car parts, as well as numerous scenes in the large shops at Puteaux.

Gramm-Logan Motor Car Company, Bowling Green, O.—Facts relative to the economic use of the commercial vehicle are ably presented in the catalogue of the Gramm-Logan Company, recently issued. The book is gotten up in the same style and with the same evident care as that bestowed upon the best of the publications illustrative of the modern high-priced pleasure cars, bound in heavy stock of a pleasing blue color. Gramm-Logan trucks are built in numerous styles, upon three general chassis models, depending upon the loads to be carried, using water-cooled motors for the large machines, and air-cooled ones for the light delivery wagons and buses. The features of these engines, as well as of the transmissions, general driving mechanism, axles, ignition system, etc., are explained in detail, and illustrations given of the different kinds of bodies which can be secured upon short notice. A double page, in the center, is devoted to a comparison of the cost of horse-drawn transportation as compared to that of the Gramm-Logan trucks, based upon actual work, and shows conclusively the advantages of the latter.

Prominent Autoists Tour in Cuba

This photograph was taken on a recent trip to the Queen of the Antilles by H. S. Firestone, president of the Firestone Tire & Rubber Company; James Couzens, secretary and treasurer of the Ford Motor Company, and Frank Presbrey, general advertising agent, of New York. These autoists did considerable touring while in the island.

Cartercar Company, Pontiac, Mich.—Friction-driven Cartercars are well known throughout automobile circles, particularly because of their transmission feature, and further details of this, as well as of the other parts of the cars, are narrated in the new catalogue, No. 10, just received. A number of illustrations are given, the frontispiece being a reproduction of a photograph taken of a Cartercar in service on Mount Hamilton, Cal., running to and from the Lick observatory; there are cuts showing factory details—the motor assemblage, that of the new chain-in-oil drive, and, finally, several of the completed cars to show their various body types. The Cartercar Company has recently moved into its new factory, with the most modern equipment and ample facilities for the construction of a large number of machines annually. The catalogue mentions this and gives an interesting sketch of the origin of the friction transmission. Seven styles of bodies for Cartercars are shown pictorially—touring cars, runabouts, roadsters, coupés, taxicabs, and commercial vehicles being represented.

Diamond Rubber Company, Akron, O.—Motor truck tires, both of the wire mesh base and side wire types, are described in the most recent publication of the Diamond Rubber Company. The covering of this book is one to instantly attract attention, in that it is a brilliant red color, with gilt trimmings, and the descriptive matter in the interior is well printed on heavy, cream-colored stock. The material used in the Diamond products is called to attention, the reasons for certain processes, and then the regular catalogue features are taken up. Not only are the various tires illustrated as to their general appearance, but also their cross-sections, and tables of sizes. Machines for applying the side wire tires are illustrated, and directions given for their use, so that the book contains a fund of information, especially valuable to those engaged in commercial businesses, for these tires are applicable to horse-drawn vehicles as well as automobiles.

Bartholomew Company, Peoria, Ill.—"Logic, which has developed the Glide car, and the reasons for its low cost of upkeep" is the title of a pamphlet issued by the Bartholomew Company recently. It is as interesting as its subject would indicate, in that it takes up the reasons for certain points in the construction of the Glide, for instance, showing why the spokes of the wheels were gradually increased from a diameter of 1¼ inches to 1⅝ inches, and why the rear driving axle was enlarged from 1¼ inches to the present 2 inches, both now fulfilling the requirements where the smaller sizes were found too light. Similar comparisons are made to show why the Glide has but one universal joint, whereas when the Glide was first built there were other manufacturers who were using two, three, and in cases four.

Wonderful Car Illumination by Apple Electric System

In the parade for the Wright brothers' homecoming celebration at Dayton, Ohio, the car of V. G. Apple attracted very much attention, being outlined with electric lights. In all 260 tungsten lamps were used, the current being supplied from an Aplco electric lighting outfit.

RECENT INCORPORATIONS

Regal Tire & Rubber Company, Camden, N. J.—Capital, $250,000. To manufacture automobile, carriage and other tires. Incorporators: W. H. Wilson, Stewart Murray, Frank A. Kuntz, W. C. Reinhold.

Eastern Auto Transit Company, Albany, N. Y.—Capital, $35,000. To operate a stage line between Albany and Schenectady. Incorporators: William A. Cryne, Edward D. Wintersteen, Charles B. Henry.

Quadruplex Auto Tube Company, Wilmington, Del.—Capital $600,000. Incorporators: Phelan Beale, 150 West Forty-seventh street, New York; M. D. Nave, G. U. Smith.

Queen City Auto Livery Company, Buffalo, N. Y.—Capital, $25,000. To operate an automobile livery service. Incorporators: C. V. Roty, H. C. Shufeldt, W. J. Hickey.

Morrison Motor Car Company, Chicago—Capital $20,000. To manufacture automobiles and accessories. Incorporators: J. T. Morrison, H. E. Piermont, O. H. Wolfe.

Electric Service Company, New York—Capital $50,000. To manufacture automobiles and accessories. Incorporators: W. L. Ernst, M. E. Harby, A. A. Ernst.

Waterhouse Carbureter Company, Boston—Capital, $100,000. To manufacture and sell motors of all kinds. Incorporators: H. D. Waterhouse, F. C. Hersee.

Jean Flying Machine Company, New York—Capital $5,000. To manufacture flying machines. Incorporators: Octave Jean, C. S. Horowitz, Herman Weiss.

Anderson Airship Company, New York—Capital $25,000. To operate vehicles through the air. Incorporators: J. J. Harper, E. J. Forhan, H. M. Browne.

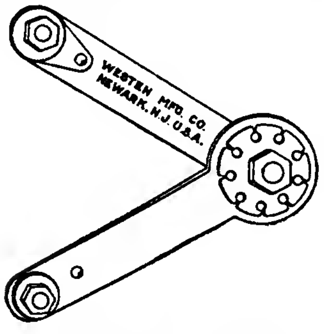
Cole Motor Car Company, Indianapolis—Capital, $100,000. To manufacture and sell automobiles. Directors: J. F. Morrison, J. J. Cole, Nellie G. Cole.

Brazier Garage Company, Philadelphia—Capital, $100,000. Incorporators: Carter G. Glenn, James K. Davis, John Y. Sinton, Robert Summers.

Automatic Inner Tube Company, Wilmington, Del.—Capital, $350,000. Incorporators: A. M. Bango, A. R. Bango, G. G. Steigler.

Information for Auto Users

Shock Absorbers Make Riding Easy—Tours like the Glidden, at the same time extended and strenuous, have done much to bring into use shock absorbers and other devices designed to make for easy riding. In the jolt-eliminator, made by the Westen Manufacturing Company, 290 Halsey street, Newark, N. J., two friction planes are used to check all large oscillations. Of these, the smaller is

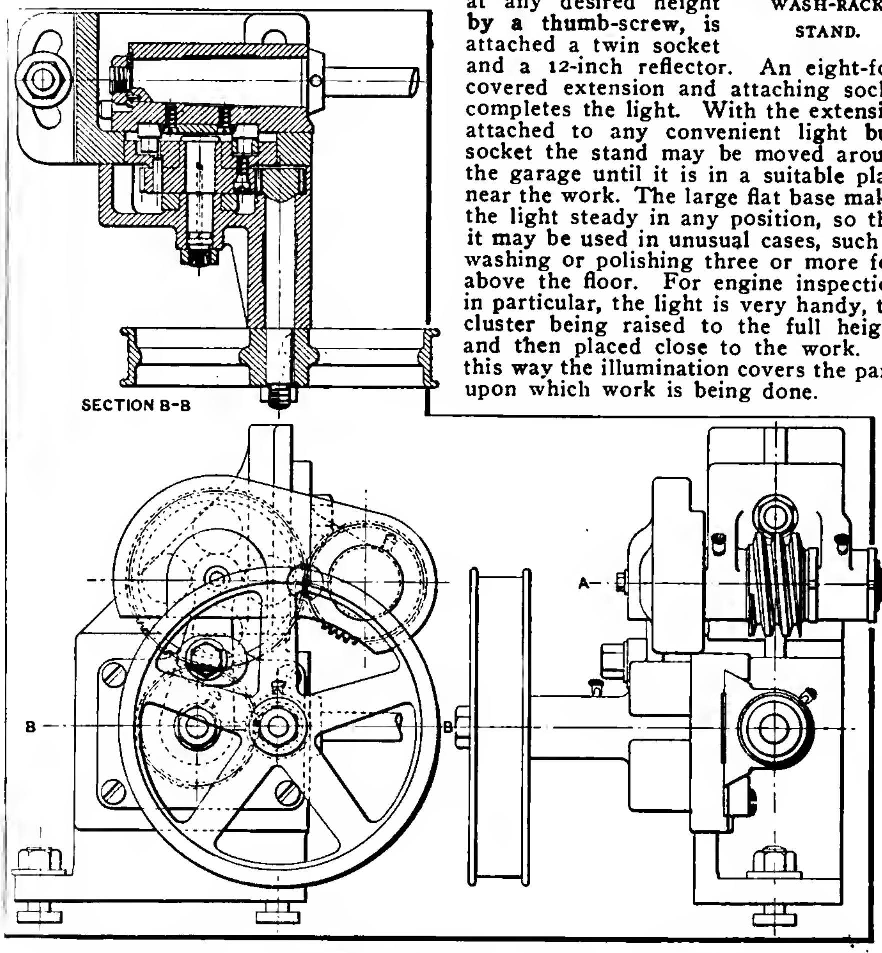


WESTEN SHOCK ABSORBER.

brought into use on small obstructions, such as are met ordinarily, while the larger plane comes into active use only on very rough surfaces resulting in unusual bumps. This makes for simplicity of construction and consequent adjustment, which is well worthy of consideration on the part of the new driver. After being once set—that is, when both planes have been adjusted—the makers say that no further adjustment is necessary. There are no moving mechanical parts to get out of order. In external appearance, as the line cut above shows, this device for making automobiling more pleasant resembles an older and well-known absorber.

A Handy Tire Inflator—Back breaking is a phrase which no longer applies to tire inflation, for the number of devices which are designed to eliminate the manual labor connected with tire inflation is augmented daily. The latest thing out is the Prest-O-Tire tube, made by the Prest-O-Lite Company, Indianapolis, Ind. This is a very small and consequently very compact tube filled with compressed carbonic gas. The supply carried in one of these little tubes, which take up practically no room in the tool box, is sufficient to inflate completely one large 36 by 5 inch tire, or, used with care, it will pump several deflated tubes. In use, it is the acme of simplicity, a valve and hose attachment screws into the end of the gas tube, thereby puncturing a metal cap in the end of the tube. This allows the flow of gas as soon as the valve is turned on. The other end of the rubber tube is attached to the tire valve, hand valve or supply cock is turned on and the compressed gas inflates the tire. The tube itself is but 1 1-4 inches in diameter by 12 inches long and weighs but one pound when filled. As the tubes cost but a dollar each, and, empty, are redeemable for 80 cents, the expense of inflating a tire in this manner is very small.

Improved Tooth Chamfering Machine—The increasing use of gears and with that the greater use for chamfered gears has naturally brought out machines for doing this work, thus replacing the slow and costly hand work. Of these machines one of the better known is that of the Long Arm System Co., Cleveland, O., of which the up-to-date improvements are worthy of mention. The machine itself is too well known to require any additional mention, but since it was first brought out several changes have been made. Thus the spindle position has been changed from a vertical to a horizontal one. By adding a tail stock, possible with this position. the range of work has been much extended. In addition to this, the new position allows chamfering gears in the middle of an integral shaft, which could not be done before. So, too, with unusual angles, it is now possible to swivel the attachment to such an angle as to do any desired form of chamfering. It is an improvement as far as the parts are concerned, for the chips do not fall on the work, and the wear on both cams and rollers is balanced at all times. The countershaft and consequently the whole driving mechanism are simplified, while the present direct belt drive does away with the idler pulley and balance weight. The cut shows a section through the working spindle, an end view and a side view.



THREE VIEWS OF THE LONG ARM SYSTEM COMPANY'S TOOTH CHAMFERING MACHINE.

Saves Electric Light Bills—Everybody loves the electric light companies so, and takes such delight in paying the light bills, that doubtless a device for economizing on the current used will not become popular. The Portland Wash-Rack Stand, made by the Brown Company, Syracuse, N. Y., does this by presenting a secure basis for the light fixture, and at the same time permitting of its movement toward the work so that superior illumination is secured from the same or a lessened number of lights. For garages, either public or private, this should prove invaluable. It consists of a four-footed flat base, hung low for steadiness, and provided with space for holding small articles in use while the light is being used. From this base, extending upward, is a three-foot riser or vertical upright, which, in turn, supports a special design of carrying bracket. On this bracket, which is held at any desired height by a thumb-screw, is attached a twin socket and a 12-inch reflector. An eight-foot covered extension and attaching socket completes the light. With the extension attached to any convenient light bulb socket the stand may be moved around the garage until it is in a suitable place near the work. The large flat base makes the light steady in any position, so that it may be used in unusual cases, such as washing or polishing three or more feet above the floor. For engine inspection, in particular, the light is very handy, the cluster being raised to the full height, and then placed close to the work. In this way the illumination covers the parts upon which work is being done.

PORTLAND WASH-RACK STAND.

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, JULY 8, 1909—CHICAGO No. 2

THE AUTOMOBILE

NEXT THE BIG TOUR OF THE YEAR

DETROIT to-day is the Mecca of Autodom. Thither are headed those who will participate in the annual tour of the American Automobile Association, involving the winning of the Glidden, Hower and Detroit trophies. The first of these is historic in American automobiling, and the 1909 winner will earn his honors in a more strenuous test than has ever been projected in the way of a prolonged endurance tour in this country.

From Detroit to Kansas City, by the route to be followed, the distance will exceed 2,600 miles, and the roads met with will embrace good, bad, and indifferent, with possible wet-weather complications to add to the trials and tribulations of cars and drivers. In July 'tis likely to be hot.

But the great Middle West will enjoy the spectacle of a big contest tour, which unquestionably will add to the prestige of the motor-driven vehicle and bring to the attention of thousands its pleasurable necessity.

Preceding the official start of the tour on Monday morning next, there will be several days of "doings" in the "City of the Straits," which has prepared an elaborate program such as might be expected from a city of Detroit's importance in automobiling. 'Tis really the capital of American motordom, for its enormous factories turn out most of the thousands of cars being produced.

That many will visit Detroit for the sole purpose of seeing the start, is known to be the case, for the hotel accommodations of the city have been tested to their limit, to accommodate the excess of visitors.

Once upon a time, in the palmy days of cycling, Detroit entertained the League of American Wheelmen. Now it is to be the host of the autoists who have succeeded the lowly cyclers; and, mayhap, a decade hence, the same hospitable city will stretch forth the hand of welcome to the aerial brigade in one of its annual gatherings.

It is notable that the conditions for the 1909 tour are wholly different from those of former years. For the first time the Glidden trophy is up as a prize for an individual, to be held by him for one year. It will no longer go to a club nor be competed for by teams. In order to permit of this and of the increased distance, it was necessary that the deed of gift be altered and this was done with the consent of the donor, Charles J. Glidden, who will be on the tour.

Besides the Glidden trophy there are two others, each of which becomes the permanent possession of its winner this year. First of these is the Hower trophy for runabouts, and this will be the third Hower trophy to be awarded. The other prize is a new one offered under unusual circumstances. It is a trophy for the miniature tonneau car making the best score and is known as the Detroit cup. In appreciation of the honor of having the tour start from their city the members of the Detroit Board of Commerce agreed to donate a trophy to be competed for by miniature tonneau cars. The Mayor and Common Council of the city got ahead of the merchants, however, and for the first time on record an appropriation from the city treasury was voted for a trophy, without the matter being referred to a committee. The Common Council voted $250 for the prize and a committee, headed by Mayor Breitmeyer, was appointed to make the purchase. The Mayor found the sum insufficient and added $250 from his private purse.

The rules for 1909 are more strict than any former set, and cars will be penalized in fractional marks for any work done on them. All the extra parts and tools carried will be listed, an observer will ride on each car, and there will be an inspection of the parts and tools at the finish and perhaps during the tour. The system of penalization has been worked out by tenths of a point, so as to make it reasonably certain that a winner will be evolved, and yet no car be heavily penalized for repairs that are trivial and quite ordinary. The cars will be divided into five comprehensive classes this year, separated as follows:

Class A—Cars listed at $3,751 and upwards.
Class B—Cars listed at $2,451 to $3,750 inclusive.
Class C—Cars listed at $1,751 to $2,450 inclusive.
Class D—Cars listed at $1,000 to $1,750 inclusive.
Class E—Cars listed at $999 and under.

Henry Souther, the well-known technical expert, and Joseph Tracy, noted both as an expert and a driver, will serve with Chairman Hower on the special technical committee.

THE LIST OF PARTICIPANTS

About fifty cars will participate in the 1909 tour. The entries July 4 numbered forty-seven, and to this will be added several post-entries, mostly non-contestants. Herewith is the rather incomplete data available just before going to press:

FOR THE GLIDDEN TROPHY

No.	Car	Entrant or Driver	Address
1	Premier	Webb Jay	Chicago
2	Premier	George A. Weidely	Indianapolis
3	Chalmers-Detroit	William Bolger	Detroit
4	Marmon	H. C. Marmon	Indianapolis
5	Marmon	Frank E. Wing	Boston
6	E-M-F	E-M-F Company	Detroit
7	E-M-F	E-M-F Company	Detroit
8	E-M-F	E-M-F Company	Detroit
9	Maxwell	E. G. Gager	Tarrytown, N. Y.
10	Jewel	C. P. Bernhart	Massillon, O.
11	Pierce-Arrow	F. S. Dey	Buffalo
12	Pierce-Arrow	W. C. Winchester	Buffalo
14	Glide	A. Y. Bartholomew	Peoria, Ill.
15	Thomas	Gus G. Buse	Buffalo
16	Midland	E. O. Hayes	Moline, Ill.
17	Stoddard-Dayton	Dayton Motor Car Co.	Dayton, O.
18	Stoddard-Dayton	Dayton Motor Car Co.	Dayton, O.
19	White	H. N. Searles	Cleveland

FOR THE HOWER TROPHY

No.	Car	Entrant or Driver	Address
100	Moline	C. H. VanDerVoort	East Moline, Ill.
101	Moline	J. A. Wicke	East Moline, Ill.
102	Moline	Sylvester Gregory	East Moline, Ill.
103	Brush	Frank Briscoe	Detroit
104	Brush	Frank Briscoe	Detroit
105	Chalmers-Detroit	J. Machasky	Detroit
106	Hupmobile	F. Stineman	Detroit
107	Maxwell	Charles Goldthwaite	Tarrytown, N. Y.
108	Pierce-Arrow	J. S. Williams	Buffalo
109	Pierce-Arrow	C. Schofield	Buffalo.
110	McIntyre	Frank Goodwin	Auburn, Ind.
111	Stoddard-Dayton	Dayton Motor Car Co.	Dayton, O.
112	Jewel	Jack Shimp	Massillon, O.
114	Mason	F. S. Duenenberg	Des Moines, Ia.
115	Lexington	J. C. Moore	Lexington, Ky.
116	Stoddard-Dayton	Dayton Motor Car Co.	Dayton, O.

FOR THE DETROIT TROPHY

No.	Car	Entrant or Driver	Address
51	American Simplex	Simplex Motor Car Co.	Mishawaka, Ind.
52	Chalmers-Detroit.	Chalmers-Det. Mot. Co.	Detroit.
53	Premier	H. O. Smith	Indianapolis.

NON-CONTESTANTS

No.	Entrant	Car	Address
75	General Service	Rapid Truck,	Pontiac, Mich.
76	"The Automobile" & "Motor Age".	Thomas,	N. Y. & Chicago.
77	77 Diamond Rubber Co.		Akron, O.
78	B. F. Goodrich Co.		Akron, O.
79	Press	Maxwell,	Tarrytown, N.Y.
80	Press	Maxwell,	Detroit, Mich.

OFFICIAL

No.		Car	Address
98	Pilot	E-M-F,	Detroit, Mich.

97	Pilot	E-M-F,	Detroit, Mich.
96	Secretary and Starter	Acme,	Reading, Pa.

ITINERARY OF THE 1909 A. A. A. TOUR

Date	Route	Miles
July 12	Detroit to Kalamazoo	142.3 miles.
13	Kalamazoo to Chicago	173.3
14	Chicago to Madison	175.2
15	Madison to La Crosse	154.4
16	La Crosse to Minneapolis	177.8
17 & 18	Remain at Minneapolis.	
19	Minneapolis to Mankato	132.0
20	Mankato to Fort Dodge	138.6
21	Fort Dodge to Council Bluffs	181.0
22	Council Bluffs to Kearney	200.2
23	Kearney to Julesburg	206.2
24	Julesburg to Denver	204.8
25 & 26	Remain in Denver.	
27	Denver to Hugo	173.5
28	Hugo to Oakley	165.0
29	Oakley to Salina	199.7
30	Salina to Kansas City	212.8
	Total mileage	2,636.8 miles.

The route is indicated more fully by the following itinerary, giving the principal places passed between the night stops:

Detroit, Ann Arbor, Jackson, Battle Creek, Kalamazoo, Mich.; South Bend, La Porte, Ind.; Chicago, Waukegan, Ill.; Racine, Milwaukee, Madison, La Crosse, Wis.; St. Paul, Minneapolis, Mankato, Minn.; Fort Dodge, Council Bluffs, Iowa; Omaha, Fremont, Grand Island, Kearney, Cozad, North Platte, Neb.; Julesburg, Fort Morgan, Denver, Colorado Springs, Hugo, Col.; Sharon Springs, Oakley, Hays, Salina, Topeka, and Kansas City, Mo.

For the benefit of those who will want to communicate with the tourists a list is supplied telling where to address mail at various places. This is as follows, the date of the tourist's arrival being given first:

Date—Place	Address
July 12—Kalamazoo, Mich.	Burdick House.
" 13—Chicago, Ill.	The Annex.
" 14—Madison, Wis.	Avenue Hotel.
" 15—La Crosse, Wis.	Stoddard Hotel.
" 16—Minneapolis, Minn.	West Hotel.
" 19—Mankato, Minn.	Saulpaugh Hotel.
" 20—Fort Dodge, Iowa	General Delivery.
" 21—Council Bluffs, Iowa.	Grand Hotel.
" 22—Kearney, Neb.	General Delivery.
" 23—Julesburg, Col.	General Delivery.
" 24—Denver, Col.	To be announced later.
" 27—Hugo, Col.	General Delivery.
" 28—Oakley, Kan.	General Delivery.
" 29—Salina, Kan.	General Delivery.
" 30—Kansas City, Mo.	To be announced later.

Express packages should be sent to the hotel when one is given as the mail address. At Fort Dodge, Iowa, express matter should be sent care of the station agent of the Great Western Railroad. At Kearney, Julesburg, Hugo, Oakley, and Salina, anything sent by express may be addressed in care of the Union Pacific station agent.

HOW SLEEPING CARS WILL SERVE AS HOTELS

Every year there has been trouble finding suitable over-night accommodations for the two hundred and odd tired, dirty, and hungry participants of the tour, but this year the problem was a really formidable one, owing to the size of some of the places

Moline Dreadnaught Squadron Which Will Compete for the Hower Trophy

Contestants in the Sixth Annual A. A. A. Reliability Touring Contest Will Traverse Ten States

where it is necessary to call a halt. These details Chairman Hower of the A. A. A. touring board had to wrestle with and settle, and he finally found that the only way possible to run the tour over the chosen route would be to engage sleeping and dining cars, to be side-tracked at the night stops from Fort Dodge to the finish, which will be ten and a half days. The Pullman people would not permit the cars to be summoned and dismissed at will, so that after they are once brought into requisition they will have to be used (or at least paid for) even in the places where hotel accommodations are to be had. The arrangements call for six sleeping cars, three dining cars, and a headquarters car for the officials and their outfit. At Council Bluffs a baggage car will be added for the use of the tire makers who send along supplies. Although the sleeping and dining cars will be used at Council Bluffs, the headquarters will be at the Grand Hotel. The tourists will sleep in the Pullman berths and will get not only their dinner at night and their breakfast in the dining cars, but also will receive each day a lunch put up in a box. Concerning the arrangements for the Pullman cars Chairman Hower has issued a special notice to participants which, in part, reads:

"There has been some difficulty in making arrangements with the Pullman people, but through the efforts of F. C. Donald, commissioner of the Central Passenger Association, we have been successful in completing what promises to be very satisfactory arrangements. For the ten-and-one-half days the contestants will rely on the Pullman service, there will be a charge per day of $7.45 for each person, making a total of $78.23 for each person for the entire number of days. This charge includes breakfast, lunch, dinner, and lodging. Qpite naturally it was necessary for us, in completing these arrangements, to agree to pay the Pullman company the entire amount prior to the start, as they must complete their negotiations for the entire trip."

This price, it is estimated, is not more than it usually has cost the tourists per day, all told, when they stopped at the big hotels.

The Pontchartrain hotel, where Chairman Hower is now located, is the headquarters at Detroit.

DETROIT WILL SUPPLY GRAND SEND-OFF

Detroit, July 6—Visitors to Detroit during "Glidden tour days" will be afforded an impressive object lesson on the hold the automobile has taken on local enthusiasts. One week before the actual opening of the festivities in connection with the A. A. A. tour, nearly one thousand automobiles had been entered in the big parade for Saturday July 10, which it is planned to make the crowning event of the occasion. It is expected that when the lists have been completed, this number will have been exceeded, and that the greatest spectacle in the history of the industry will result. More than $700 worth of valuable trophies will be awarded the best decorated cars in each division, there being eight prizes in all. These are:

The most beautiful car in the parade, any description.
The best decorated car driven by a lady.
Best decorated electric car and second best.
Best decorated gasoline or steam car and second best.
Best decorated commercial vehicle and second best.
First, second and third best decorated motorcycles.

In addition, several hundred dollars will be distributed in prizes to contestants in the athletic events taking place at Belle Isle at the conclusion of the parade. The parade will start on North Grand Boulevard, at 1:30 Saturday afternoon, the route being through the center of the city to Jefferson avenue and east to Belle Isle, where a panoramic picture of the procession will be taken. Following this will be the inter-factory athletic con-

Possibly the most enjoyable feature of the "Glidden tour day's" entertainment (inasmuch as it will take the guests away from shop talk and familiar scenes and give them a new conception of the advantages enjoyed b ythe hub of the automobile industry will be the boat ride to be tendered tourists and others on Sunday on the steamer *City of Cleveland*. The boat will leave the city at noon, running down to Lake Erie, turning about and going up past the city and across Lake St. Clair to the St. Clair Flats, the Venice of America, returning to Detroit early in the evening, so that the tourists will be able to

The festivities will open with a banquet Friday evening at the Hotel Pontchartrain, to tourists, A. A. A. officials, and visiting newspaper men, at which it is promised that something more than good feelings will be uncorked. The committee in charge

Indications are that Detroit will be invaded by the most representative body of automobile men it has ever had the honor of entertaining. All the accommodations planned for have been taken, and there are still many to be heard from. The following program has been arranged for the entertainment of the visiting tourists:

Friday Evening, July 9—7:30, Hotel Pontchartrain, banquet to the A. A. A. officials and directors.

Saturday, July 10—From 9 to 12 a. m., automobile manufacturers receptions at the factories.
From 1 to 3 p. m., street parade of decorated automobiles.
From 3 to 4:30 p. m., ball games and athletic sports at Belle Isle Athletic Grounds.
4:30 p. m., entertainment to the Executive Board of the A. A. A. by the Automobile Club of Detroit.
7:30 to 9:30 p. m., band concern on the campus in front of the City Hall.

Sunday, July 11—12 to 5:30 p. m., river excursion on the palace steamer, City of Cleveland, up the Detroit River, through Lake St. Clair and the Flats. Lunch served on board from 12:30to 2:30.
Sunday evening, rest.

Monday, July 12—Tour starts with demonstration, bands, military salutes, etc.

A. Y. Bartholomew in the Glide Entry, No. 14

ONE MAN'S OPINION OF THE TOUR

By H. O. Smith, Chairman A. M. C. M. A.

With more than forty cars entered in the Glidden tour, America's automobile touring classic, it is evident that this great annual event, which means so much to the industry at large, is more popular than ever. Vague and unfounded rumors have tried to impress upon the public that the Glidden tour was not wanted by the manufacturers and the automobile purchasing public. The large list of entries fully demonstrates that the makers thoroughly believe in this great event.

It is my desire to see this year the best Glidden that has ever been held. There is no question in the minds of those who have closely followed this tour that it has done more for the automobile industry than any racing or touring event which has ever been held in America.

The Glidden has worked wonders for the industry and pastime. It has shown the makers the good and bad points in their cars. It has given the makers the opportunity to try out the cars and locate the strong and weak points with the view of perfecting them. One may say that the maker can take his car on the road, put it through all kinds of stunts, climb steep hills, make it wallow through deep sand and over bad roads, and learn just what the car is capable of doing. To a certain extent this is true, but running under schedule and strict regulations means more to the maker than could be learned in private tests.

I know of many concerns that have entered the Glidden with what they supposed was a perfect car, and when the tour was finished opened their eyes in wonderment at little things which were supposed to be strong details but turned out to be weak. I have in mind one concern that had widely advertised the superiority of their braking system, and thoroughly believed that the brakes were right, but in going over a section of hilly country in the tour two years ago, every member of the crew was standing on the running boards ready to jump if the brakes gave way. To-day this concern is making good brakes, and brakes that would hold the car on the roof of a house. There are many other similar lessons to be drawn from the Glidden.

The buying public demand the Glidden, and watch with keen interest the result and the progress of the cars during the event. They feel safe in buying a car that goes through the tour with a perfect score, or even with a good showing.

It is interesting to compare the list of entries in this year's event. For the first time in its history a buggy type car has been entered in the McIntyre. This little car will be closely watched by those interested in this type. Interest will also center on the wonderful little \$500 Brush with one cylinder. Other cars which will be the cynosure of all are the Marmon. Premier, Maxwell, Glide, Midland, Stoddard-Dayton, Moline, American Simplex, Rapid Truck, and others.

The McIntyre is a High Wheel Entry from Indiana

HOW MINNEAPOLIS WILL ENTERTAIN

Minneapolis, July 6—The citizens of Minneapolis, headed by the Minneapolis Automobile Club, have raised a fund of several thousand dollars and appointed a committee of entertainment. headed by Col. F. M. Joyce, president of the State Association, to give the tourists a large time. It will astonish some Eastern motorists to learn that the Minnesota A. A. A. is now the second largest State organization in the country.

One of the features illustrative of the thoroughness with which details are being executed is found in the fact that the club has ordered 400 gold and enamel cap badges, one to be presented to each of the participants in the tour and is also having printed a beautiful souvenir book of views of Minneapolis for distribution, each book properly addressed and stamped ready for mailing to home of each recipient, after its inspection. The program will be as follows:

Friday, July 16—Reception of tourists and escort to hotels.

Saturday, July 17—Forenoon: Trip in chartered trolley cars to Minnehaha Falls and Fort Snelling, where a special dress parade and guard mount will be held.
Afternoon: Special train for Savage, Minn., where a special matinee race will be held between Dan Patch and Minor Heir, the two fastest horses in the world, at the home of these champions, the International Stock Food Farm.
Evening, 8 p. m.: Illuminated automobile parade for the visitors through the city and over the parkways and boulevards. Governor Johnson, Charles J. Glidden and Frank B. Hower will act as judges to award the prizes to the contestants in the parade.

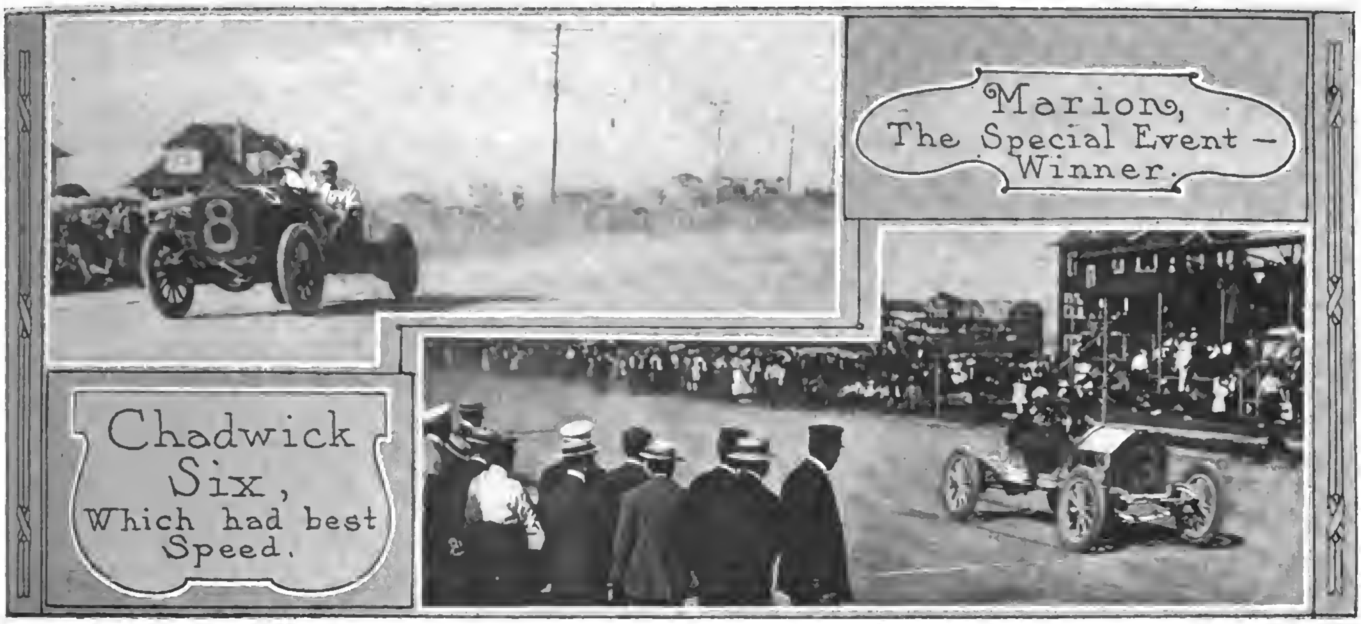
Sunday, July 18—9 a. m.: Automobile trip to Lake Minnetonka.
10 a. m.: Cruise around upper and lower lakes in chartered steamers.
1 p. m.: Dinner at Tonka Bay Hotel.
2 p. m.: Automobile trip through the country near Lake Minnetonka.
4 p. m.: Automobile Country Club, where buffet lunch will be served and a band concert by the Fort Snelling band enjoyed.

Monday, July 19—Escort by club members of the tourists on the road to Mankato.

PIERCEITES ARE FROM VARIOUS CITIES

Buffalo, July 6—Although the Pierce-Arrow Motor Car Company, of Buffalo, never has maintained a team of professional drivers for contests it has been uniformly successful in endurance runs. It would be hard to find a group of men with more widely segregated homes, in fact, than the eight who will have the Pierce-Arrows in charge in the Glidden tour this year. No two of them come from the same city. Some have had experience in A. A. A. tours before, others have not, but all are thoroughly impregnated with enthusiasm for the contest.

Two six-cylinder, 48-horsepower Pierce-Arrow touring cars will compete for the Glidden trophy. Forbes S. Dey, of Kansas City, will drive one, with E. M. Grady, of Denver, as his mechanic; while Walter F. Winchester, of Buffalo, will pilot the other, with A. A. Ledermann, of Utica, as mechanic. For the Hower trophy, two six-cylinder, 36-horsepower runabouts have been entered, the first to be driven by John S. Williams, of New York, with Andrew J. Hettrick, of Philadelphia, as mechanic. Charles Schofield, of Detroit, will be at the wheel of the second runabout and Frank Jungjohann, of Davenport, Iowa, will be in the mechanic's seat.



CHADWICK SETS NEW RECORD IN WILDWOOD MEET

WILDWOOD, N. J., July 5—Independence Day was fittingly celebrated at this resort to-day in its most successful automobile carnival. Not only were there well entered handicap events, a large attendance, and a well policed course, but there was also that charm of an automobile race meet—breaking of fast records. To the Great Chadwick Six stock car, driven by Len Zengle, belongs the honor of the day in clipping more than a good second from the best previous time over a mile straightaway on Central avenue. In a special event, the climax of a series of good ones, this car flew down the gravel course in 41 seconds, a speed of 87.8 miles per hour, and well within the time set last year by Schill, of :42 3-5.

There were eight regularly scheduled contests for the afternoon, but these were increased by the fullness of the field and the consequent necessity of running heats. Then in the special time trials each of the six machines were given two attempts, and so the enthusiasm of the 10,000 people who lined the course was kept at a high pitch. Under the direction of Fred J. Wagner the cars were started, and the arrangements for the meet were so well handled that there were no tiresome intermissions, there was no friction between the participants, and the event has well been called the most successful ever held here.

A very important feature of the contest was that the machines were all of the stock class, many stripped of course, but there were no special racers, and the popular interest seemed to be increased thereby. The Chadwick and the two Knox cars were the victors in practically every event, but they had some speedy runners-up, and there were no walk-overs. Of the dozen times that the cars covered the distance in competition, the Knox team won five, the Chadwick three, the Marion two, an Allen-Kingston one, and one was a tie between a Knox and the Marion. Many trips were made in less than the minute, and it was sometimes necessary for the drivers to shut off their power before finishing even then. The track was in splendid condition and the finishing end had been improved so that there was less danger in stopping. Handicapping was carried out by price, there being a second for each $200 difference, and the contestants were started off with the time allowance so that the finishes were true. This method may not always be as satisfactory or accurate as piston displacement ratings, but it furnishes good sport, and that was the chief aim to-day.

The police of the island were ably assisted by the Ninth company of the Boys' Brigade of Philadelphia, who were in their khaki uniforms and carried regulation rifles. They kept the crowds back as well as the most efficient regular infantry. The referee was W. Clive Crosby, and the judges were H. U. Sharpe, H. A. Bonnell, and C. A. Woolson. The summary:

TIME TRIALS OVER THE ONE-MILE COURSE, TWO TRIALS TO EACH ENTRANT

Pos.	Car	H.P.	Driver	Time
1	Chadwick	60	Len Zengle	:44 :48 4-5
2	Allen-Kingston	48	Hugh Hughes	:49 :50
3	Knox	48	Al. Dennison	:49 1:06
4	Knox	38	W. A. Bourque	:52 :53
5	Marion	32-35	Charles Stutz	1:01 8-5 1:04
6	Knox	38	J. V. W. Westervelt	1:06 1:07

SPECIAL TRIAL FOR TRACK RECORD

1	Chadwick	60	Len Zengle	:41
	Best previous time			:42 3-5

KILOMETER TRIALS

1	Chadwick	60	Len Zengle	:26
2	Knox	48	Al. Dennison	:28
3	Knox	38	W. A. Bourque	:31 1-5
4	Buick	30	E. Wilkie	:32
5	Marion	32-35	Charles Stutz	:37

FREE-FOR-ALL

1	Chadwick	60	Len Zengle	:48 2-5
2	Knox	48	Al. Dennison	
3	Knox	38	W. A. Bourque	

GASOLINE CARS, HANDICAPPED ACCORDING TO REPUTATION OF CAR AND DRIVER

1	Marion	32-35	Charles Stutz	1:11 2-5
2	Knox	48	Al. Dennison	1:16 1-5
3	Knox	38	W. A. Bourque	1:16 2-5

HANDICAP, GASOLINE CARS, ONE SECOND FOR EACH $200 IN VALUE

1	Knox	48	Al. Dennison	1:08
2	Atlas		Elmer Knox	
3	Marion	32-35	Charles Stutz	

HANDICAP, GASOLINE CARS COSTING FROM $850 TO $2,000; ONE SECOND FOR EACH $200 IN VALUE

1	Marion	32-35	Charles Stutz	1:14 2-5
2	Buick	30	E. Wilkie	
3	Overland	28	George L. Ries	
4	Mitchell	30	W. M. Cram	

HANDICAP, GASOLINE CARS COSTING FROM $2,000 TO $3,000; ONE SECOND FOR EACH $200 IN VALUE

1	Knox	38	W. A. Bourque	1:00 1-8
2	Chalmers-Detroit	40	C. J. Rodgers	
3	Knox	38	J. V. W. Westervelt	

HANDICAP, GASOLINE CARS COSTING FROM $3,000 TO $4,000; ONE SECOND FOR EACH $200 IN VALUE

1	Allen-Kingston	48	Hugh Hughes	:58
2	Knox	48	Al. Dennison	

INDIANAPOLIS SPEEDWAY GETS ITS FIRST SANCTION

INDIANAPOLIS, Ind., July 5—After many months of preparation the Indianapolis speedway has been so nearly completed that the director of contests, E. A. Moross, has secured a sanction from the Americal Automobile Association for the first race meet. On August 19, 20, and 21 the circuit will be the scene of the fastest races ever held in this country, and ones which will compare favorably with those on the Brooklands track in England.

According to the plans already outlined, the first day will be given over to events for the big cars at short distances, a sort of warming-up process, with record trials from one to ten miles. These will be followed by a long distance event, 250 miles, for the most valuable trophy ever given to cars whose cylinder displacement is between 230 and 300 cubic inches. The second day will have as a feature a contest of 300 miles, for cars measuring between 301 and 450 cubic inches displacement, for the Prest-O-Lite trophy. There will also be semi-final heats of the first day's free-for-all contests. As a climax the third day. Saturday, will see the finals for the free-for-all racing machines, a free-for-all handicap, and a great classic for which Wheeler & Schebler have donated a $7,500 trophy. The race will be 350 miles long, and for cars whose cylinder capacity is from 451 to 600 cubic inches, including all of the famous racers in this country or Europe.

Mr. Moross has been assured of entries from many quarters, some of which will be a surprise to the automobile industry. Such, for instance, is the statement by Henry Ford that he will rebuild his six-cylinder "999," and that it will be driven by Frank Kulick. Those makers who have been entering the recent important contests will undoubtedly be present. The trophies and prizes for this series will be the most expensive given for such an event, the value being about $10,000.

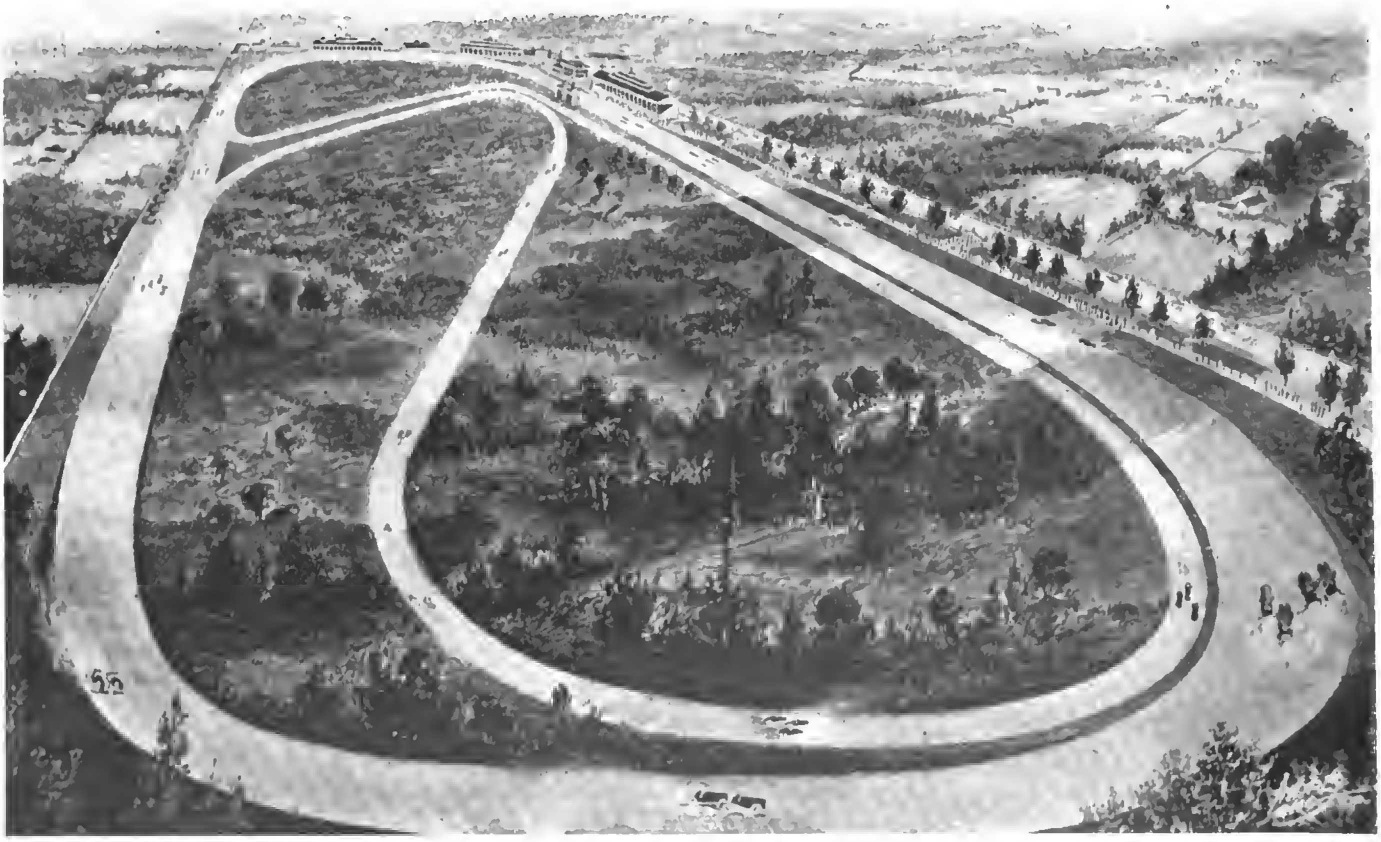
The big track is nearly finished. The top layer of gravel is now upon the straight stretches, and a concrete mixer has been requisitioned to mix the gravel and oil which will be rolled as the final dressing. The main grand stand and the smaller private ones are having their roofs made and will soon be completed. The pits are being constructed at present and there seems to be nothing that could be thought of left undone.

COLUMBUS HAS FAST TRACK MEET

COLUMBUS, O., July 3—Featured by a race of 100 miles, in which the world's record was very nearly broken, two days of automobile racing were conducted by the Columbus Automobile Club yesterday and to-day. The scene of the meeting was the local driving park, a one-mile circular track, which was in fine condition, and some very fast work was done by the professionals. In the big contest there were five starters: Lorimer and Cannon in Chalmers-Detroits, and Burman, Strang and De Witt in Buicks. Burman and Strang were the only finishers, and the time for the former was 1:44.

Perhaps the most interesting short events of the meet were the 25 miles, free-for-all, and 10 miles for the city championship. The former was won handily by Lorimer in a Chalmers-Detroit *Bluebird,* in :26 2-5, with Burman second. Barney Oldfield had his new National in this event, but had to stop because of tire trouble. In the city championship class only residents of this city and vicinity were eligible, and the race was won by a Packard, driven by Lawrence Kelly, in 11:21, with George Schlereth second, in a Pope-Hartford. There were no serious accidents.

Barney Oldfield tried to take a fall out of De Palma's one-mile record, and of Chevrolet's at five miles. His time in his new National was 4:43 1-5, which is 2 1-5 seconds more than the five-mile record, and his best mile was the last, 54 seconds, three more than the mark held by De Palma.



Bird's Eye View of the Indianapolis Motor Speedway Which Will Be Completed July 15, and Formally Opened August 19-21

With the Wrights at Fort Myer

Wilbur Wright on left and C. Taylor, their Mechanic, watching Orville Wright in flight

WASHINGTON, D. C., July 3—During the week of June 28-July 3, Orville Wright gave three successful demonstrations at Fort Myer, preliminary tuning up flights in preparation for the tests which the machine will have to pass before being accepted for the Signal Corps for the Government.

The first few attempts were failures, inasmuch as the aeroplane barely succeeded in getting off the track, and in remaining in the air but a few seconds of time, coming to earth in five different trials within short distances of the end of the starting rail. In none of these trials did the time in the air exceed thirty seconds, nor the distance three hundred yards.

Orville and Wilbur had different ideas about the cause of the trouble, Orville claiming lack of power, and Wilbur improper distribution of weight. With each successive flight, more and more power was obtained from the engine by alteration of the position of the spark and amount of gasoline feeding to the intake pipe. The Wright engine uses no carbureter, but takes gasoline directly into the intake pipe for vaporization there. Inasmuch as the minimum speed is thirty miles, and the maximum but little over forty, the Wrights believe that speed regulation, if dependent on a carbureter, would be obtained at too great a cost of unreliability and carbureter troubles.

The first successful flight came Wednesday evening, when the machine got up in the air and flew. It lacked both the lightness and ease it had last year, and appeared to labor, an impression doubtless conveyed by the steep angle which the planes had with the air. The speed, as a result of this angle—or, perhaps it is better to say, the low speed which caused this angle—was not more than 32 or 33 miles an hour during the Wednesday flights.

Thursday a short flight showed some improvement, and Friday saw the machine flying as the last year's model did—lightly, easily, with no wavering or hesitation in the air, and climbing at once and with apparent ease to an elevation of 75 feet, which was always the favorite height for Orville's flights.

Disastrous Ending to First Good Flight—The most successful flight, however, was to end in disaster. In the ninth round of the second flight of July 2 the engine either stopped in the air from an unknown cause, or was stopped by Orville in an endeavor to imitate his brother's spectacular feats in France, when, at heights of over a hundred feet, he would stop his motor and glide safely to earth. The doubt in the case is a contradiction in statements. Immediately after this glide to earth, Orville said the engine had stopped, a statement colored favorably by the fact that it had been missing almost continuously during the flights. Wilbur, on the contrary, said that Orville had stopped the engine on purpose. However that may be, at a spot almost over that on which the fatal fall of 1908 occurred, the engine stopped, the propellers ceased to revolve, and the machine made a beautiful glide to earth.

Unfortunately, Orville mistook a tree, some six or eight feet high—scarcely more than a bush—for a low clump of weeds. Too late he saw what it was on which he was to land, and too late tried to avoid it. It was struck by the extreme edge of the lower right hand plane, which was punctured by it. The tree immediately became a pivot, and the machine a compass. The forward motion was translated to movement in the arc of a circle which literally scraped the skids or landing runners from the machine. Had it not been for the tree, the glide down with motor stopped would undoubtedly have been successful. Orville said that, so far from being injured, he did not even feel the jar of the fall. As nearly as could be estimated, the glide down began at a height of 75 feet and carried him 500 feet, or at an angle of about one in seven. If Orville had any nervousness from his experience of last year it must have been dispelled from the way in which the machine behaved in thus becoming a glider. The glide down was upon an absolutely even keel and seemed under full control of the operator.

During the preliminaries and the performances of these different flights a feature of considerable interest that disclosed itself was the utter ignorance of the average person concerning even the most elementary principles of aerial navigation. Despite all that has been said and written on the subject, and the numerous successful flights that have been made, not one man in a thousand seems able to express a well-informed opinion on aeronautical prospects, or to impart a clear idea of aeroplane mechanism to friends. Even among the trained newspaper men frequent amusement would be afforded by the vagaries of an occasional rustic newsgatherer, who would insist upon interrupting efforts to give real information from the close-mouthed but good-natured Wright brothers with fool questions concerning the obvious—"Is that tall thing really the radiator, Mr. Wright?" or by dissertations on their positive understanding that the engine was formerly a two-cycle, or that, "anyway, last year a two-cycle motor was surely used."

Lack of General Information Very Apparent—General information on the subject of modern aeronautics having thus lagged so far behind actual accomplishment, a few words concerning the more fundamental principles involved can hardly be amiss, even though they be given at the risk of boring such readers as are no longer in the A B C class.

The design of the Wright aeroplane, in common with those of all others of their general type, such as the Farman, Voisin, Antoinette, Bleriot, Curtiss, etc., is fundamentally based on the very simple principle that inclined surfaces, moved rapidly through the air in an approximately horizontal direction, receive considerable support from the deflected streams of air that their angular placing causes to be forced down under them. Even with flat surfaces considerable lifts can be obtained, but with properly curved surfaces, approximating the form of the soaring bird's wing, sustensions of from two to five pounds per square foot of surface are readily to be had at speeds not in excess of 40 miles an hour.

The speed required for the requisite lifting effect demands that a flying machine of the aeroplane type be run on the ground at its slowest flying speed before it can begin to lift. In the case of the Wright machine, this initial impulse is given by towing the vehicle along at a rapidly accelerating rate, by the pull of a cable attached by a simple pulley system to a heavy, trigger-released weight that is dropped in a small "starting tower." Once in the air the horizontal travel is maintained by the thrust of two oppositely-rotating, two-bladed wooden propellers, which are said to develop a thrust of 80 pounds apiece, and which are driven by roller chain transmission from an ordinary water-cooled, four-cylinder, 30 hp gasoline engine, weighing about seven pounds to the horsepower.

Problem of Equilibrium a More Difficult One—The matters of sustention and propulsion taken care of, the considerably more complex and difficult problems of maintaining equilibrium remain to be considered. These problems reduce themselves primarily to questions of lateral and of longitudinal equilibrium. In the Wright machine, the lateral equilibrium is controlled by a single lever by the manipulation of which the wing extremities can be "warped"—that is, twisted up on one side and down on the other, or vice versa.

Steering as well as side balancing is accomplished through the wing warping, but since the wing extremities of steepest angle receive the greatest resistance as well as affording greatest lift, they tend to lag back instead of going faster, as is necessary in turning. Therefore, not primarily to steer, but simply to resist this tendency, a rear "rudder" is provided. In the Wright machine at Fort Myer this is controlled by a third lever, but in the machine used by Wilbur Wright abroad it is operated by the wing-warping lever, which is given a compound movement that it may serve the double purpose.

Obviously, the natural and most simple type of sustaining surface is the monosurface of the bird, but the difficulty of making this strong enough without exceeding the weight limit in a man-made contrivance causes the bi-plane to present a marked advantage, which is that it lends itself perfectly to a very strong and light, bridge-like, truss construction. And, with the superimposed surfaces separated a distance bearing a proper relation to the width of the surfaces, the action of one in reducing the lifting of the other is present to an immaterial extent.

This Machine Very Different from Its Prototypes—The present machine at Fort Myer has the same motor that was used last year, but otherwise is entirely new, and differs from its predecessors in a number of essential particulars. Instead of 40x6½ ft., for example, the main surfaces are now about 36x6 ft., with other dimensions reduced in proportion. One result of this change is a reduction in total area from some 580 ft. to about 490 ft., requiring, since the reduced machine has been increased in strength by not being lightened in weight, a lifting effect of 22-5 lbs. against the 2 lbs. per sq. ft. of the previous model. This, in turn, requires from two to three miles an hour more speed for a given sustention, but does not call for quite a proportionate increase in power, because the head and aerodynamic resistances are lessened by the smaller sizes. Nevertheless, in the first of the present trials certain differences were very evident to the close observer. First, there was the inability to get into the air at all at a flying speed until the motor was speeded up and the starting rail lengthened, despite attempts to secure results through a redistribution of weight.

From the action of the aeroplane during these preliminary flights, when it seemed to rear up in the air and thus diminish its speed before it was fairly launched, Wilbur got the idea that the forward planes were too light.

The Trouble Is Found and Remedied—Further attempts were made with less weight, and the machine behaved very much as before. Finally, Orville discovered that much of his trouble was due to a defective sparking mechanism, which allowed the spark to jar back almost to zero in flight, of course thus greatly diminishing the power of the engine. Further attempts proved him right, as the next day, with spark adjusted, the engine developed enough power to make a successful flight.

In the first flights that were made the machine, besides progressing at an unduly uptilted angle, seemed to lack the lightness and speed of its larger prototypes, and flew "as though it burdened the air," as one observer put it, and seemed barely able to stay up. In coming down the brunt of the contact with the ground is taken by the runner-like alighting gear. This feature of the machine also has undergone modification, the runners being now much higher than before, so as to reduce the chances of injury to the lower wing surfaces from the machine careening over in landing.

Particularly impressive are the landings, which seem quite without measurable hazard, even to the most critical. Approaching the ground at a very flat angle, the first evidence of the machine's closeness to it is the dust blown up by the propellers. Then as the runners make contact, almost as lightly as feathers, and the power is shut off, the machine quickly is retarded to a stop by the braking effect of the runners.

Difference in Flight of Two Machines Very Noticeable—Last year the invariable comment of every one who saw the machine was, "How easily it flies." Those who knew an aeroplane from an ice wagon were wont to remark upon the flatness of the angle of the planes when in the air. The difference was thus greatly marked when, in this year's flights, the machine barely dragged itself aloft and stayed there with effort.

Immediately after the unfortunate accident at the end of the glide, Orville said: "I am sorry it had to occur now, because it means delay just when the engine and the aeroplane were getting right." This is true, since the last flight before the accident showed that no mistake had been made in altering the dimensions of last year's successful machine, and that it was getting thoroughly tuned up ready to make the tests.

These tests are exhaustive and stringent. The first is a speed test. After some cogitation and exploration, the Wright brothers selected the so-called Alexandria, Va., course for this trial. The machine will get in the air, get up speed, and cross a line on the parade ground, fly five miles over rough and open country to Alexandria, Va., where it will round a small balloon and return to the fort. Time will be allowed for the turn and counted only on the straightaway, the idea being to determine the speed at which the machine flies. The price paid will depend on this speed. For 40 miles an hour the Wrights will receive the tidy sum of $25,000 for the aeroplane. For every mile in excess of this speed, up to and including 44 miles an hour they will receive 10 per cent of this amount additional. For every mile less than this amount per hour, 10 per cent of $25,000 will be deducted from the purchase price, down to and including 36 miles per hour. Less than this speed will not be accepted by the Signal Board.

The speed test must be made with a passenger on board and enough gasoline at the start to carry the machine 125 miles.

The second test is an endurance test, and must be made also with a passenger and gasoline for 125 miles. During this test the aeroplane must remain continuously for one hour in the air, during which time it must be demonstrated to be under full control, and make such evolutions in the air, right and left turns, etc., as show this to be a fact.

Further than this, the Wrights must instruct two officers in the art of aeroplane manipulation until they can fly successfully.

The lieutenants who will receive instructions are Lieut. Frank P. Lahm, in charge of the aeronautical corps, and Lieut. Benjamin D. Foulois, of that branch of the service. Lieut. Lahm is an experienced balloonist, and was the first man in America to be a Wright passenger. Lieut. Foluois is inexperienced in any but dirigible work, but an expert there.

Functions and Frailties of Motor Cylinders

By Thos. J. Fay

CORE is the name of the part of a mould, as used in a foundry, by means of which the shape of the interior of a cylinder, or other form of castings, are made. Cores are made separate from the rest of the moulds, and inserted in them at the proper time; in "coring up" in a foundry, the cores are carefully placed in position, ready for the casting process; unless the cores are rightly set the result will be as shown in Fig. 5, and the walls of cylinder will be of varying thickness, due to misplaced core, which may follow bad centering or shifting during the process of "ramming."

If cores are not provided with adequate bearing, the result may be as shown in Fig. 6, resulting in a thin dome of the cylinder, and since the greatest pressure comes on the dome it is almost sure to fail in service. Accuracy of core making depends upon accuracy of the previous core-box work, and cylinder patterns that match up. Frequently in foundries that are accustomed to the demands of cylinder casting, which is far more exacting than in the ordinary run of work, defects come from inferior patterns; which defects may be due to lack of skill on the part of the pattern maker, or lack of good material in the pattern. True, a good pattern will last but a short time in the hands of foundrymen who fail to appreciate the delicacy of the task, and who throw the patterns around as if they were of almost no importance at all.

Selected grades of seasoned Mexican mahogany will serve very well for patterns, and the cost of the material is not high enough to warrant the use of inferior wood. Since cylinders are required in quantity, and the patterns are, as a rule, in continuous use, core boxes, of pattern pine, of the first grade, may serve extremely well, especially as they are not nearly so delicate as patterns, but, as before stated, it is of the greatest importance to have the cores and the patterns match up. In actual practice there is no better plan than to take the first cylinder, after a good looking one is run off, and saw it into quarters, in the longitudinal plane, and through the valve chambers, in the same way, after which it will be possible to measure the thicknesses of walls, although, as a rule, the eye will detect differences, at sight, after the cylinders are sawed in twain.

If the walls are not of substantially the same thickness at all points, it will be well to ascertain the reason, and if it is found that the cores are not central in the pattern, as fixed by core boxes, there is nothing remaining but to make the necessary adjustments. If the core prints are without sufficient bearing, or if they shift in the process of ramming, the corrective measures should be applied, and account should be taken of the thinness of walls used in cylinders; the factor of safety being barely sufficient if the walls in castings are as in drawings, which makes little or no allowance for defects in the foundry.

Neat Match at Parting Line—In view of the difficulty in reaching the inner surfaces of cylinders in the region of the valves, it is important to have the parting line come with a neat match. As a rule the parting comes at the top, in the bore, and unless the match is neat the seam, as shown in Fig. 7, will show around the bore, and pass along the walls of the ports, just at a point where it will be difficult, or impossible, to machine away the protruding metal. Fins are very prone to heat to a point above the temperature of the rest of the material and pre-ignition will follow, especially if the compression is fairly high in the cylinders, or provided the cooling is inferior during operation.

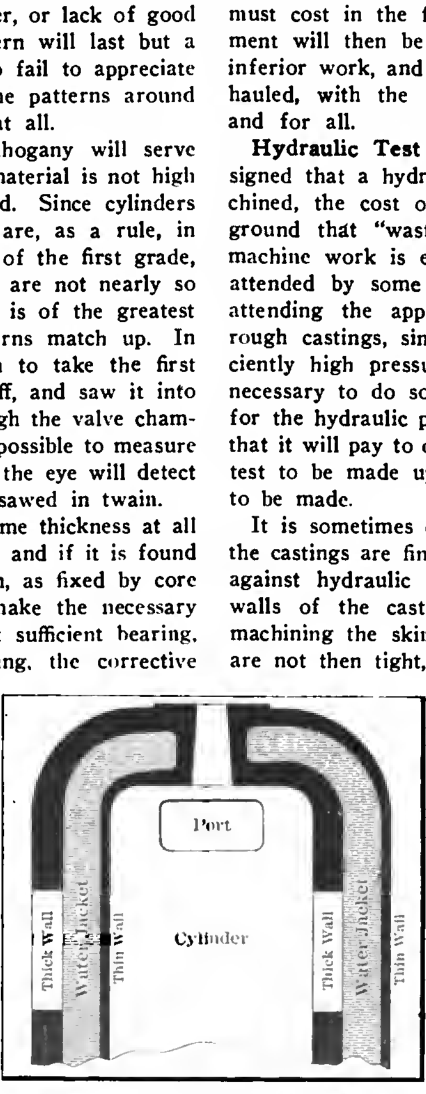


Fig. 5—Misplaced core, resulting in thin cylinder walls

The outline which separates the parts of a mould will only be neat if the foundryman is skilled—assuming patterns and core boxes do not warp—even when the pattern work is of a character above fair criticism, and while this is not a matter of great importance in ordinary casting work, it takes on extraordinary proportions in the process of casting cylinders, for the very reason that pre-ignition will follow if partings do not match, since the resulting fins cannot be removed if the space is restricted, and tools cannot be made to reach the line of parting at all points, which is usually the condition that obtains in cylinder castings. When castings are received at the plant where they are to be machined, it is a good practice to have them inspected at once, and if the workmanship is inferior a good inspector will be able to judge of the fact; to promptly advise the foundry of the condition obtaining is equal to saving must cost in the finishing process, since the foundry management will then be in a position to restrict the percentage of inferior work, and if conditions warrant patterns may be overhauled, with the expectation of correcting the defects, once and for all.

Hydraulic Test Should Be Made—If cylinders are so designed that a hydraulic test can be made before they are machined, the cost of finished product will be reduced, on the ground that "wasters" will fall by the wayside before any machine work is expended on them. This is a detail that is attended by some resistance, as a rule, due to the difficulty attending the application of hydraulic testing equipment to rough castings, since joints will only be tight against a sufficiently high pressure if they are well made. Generally it is necessary to do some facing off in order to make the flanges for the hydraulic piping as tight a fit as the occasion requires; that it will pay to do the necessary work to enable the hydraulic test to be made upon receipt of castings is one of the points to be made.

It is sometimes claimed that the test cannot be made before the castings are finished, on the ground that they may be tight against hydraulic pressure when the "skin" is on the inner walls of the castings; this is probably not true, for after machining the skin is on the outer wall, and if the cylinders are not then tight, it is proof of lack of virtue of the "skin." The average foundryman depreciates all attempts at testing that are made with a pressure above 50 to 60 lbs. per sq. in.; that this pressure is adequate for the purpose is highly improbable, and that 500 lbs. per sq. in., hydraulic pressure, will develop every defect is one of the matters that can be taken for granted.

For the purpose of making tests, by hydraulic means, high-pressure equipment, adapted for testing steam boilers, serves, and the cost of the pump and gauges, as well as tight-joint fittings, is so low as not to be a factor: less than $100 will cover the whole item of cost. Ammonia fittings, in which a system of packing is used, work very well for the purpose, and

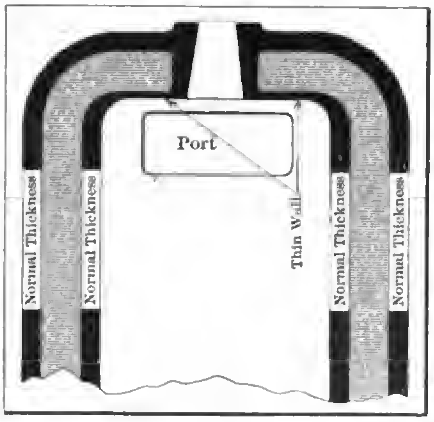

Fig. 6—Displaced core, resulting in thin dome of the combustion chamber

they have the virtue of being quickly taken apart; they can also be tightened under pressure, and to draw them up until they are tight is a very simple matter that can be intrusted to a workman of no great skill. In the absence of good and tight fittings it is impossible to make a satisfactory test, since the pressure will fall down within a few seconds of time. In testing cylinders, if they do not shoot a "geyser" at 100 pounds per square inch pressure, they will serve very well, even if a little fine spray does develop at the higher range of pressures; if the pressure is left on for a time, provided the spray does not advance to the dignity of a stream, there will be no advantage in continuing the test. That a second "inspection" test should be made on the finished cylinders is one of the matters that would seem to fall within the pale of good practice, particularly in view of the importance of cylinders in motors, and the labor item involved in changing them if they show defects in service.

Defects That Do Not Always Develop—Slag, which is the dross or recrement from metal, while it is cleared from the top of the molten mass in the cupola, for the most part will betimes entrain, and when it settles in the section of the casting the defect may be deep enough as not to uncover. Cinder, which comes from a cinder bed, if the same is used in the process of venting will, at the behest of a workman of careless proclivities, settle in the casting and may come to the surface in the process of machining, as shown in Fig. 8, so that slag and cinder, whether they uncover or not, will weaken the metal in proportion as they are present; slag, especially, is likely to abound, and in the castings that carry this increment, the strength is much reduced, thus rendering the same unfit for cylinder castings. If slag or cinder pockets uncover, the bore of the cylinder, in such a case, will show the defect, although it may not be fatal; this is a matter that has to be treated by makers of cars when they decide on the quality of the product they propose to deliver to patrons; some makers will prefer to ignore the presence of surface blemishes, if they do not come in a vital spot in the castings.

Shrinkage Defects Are Prone to Creep In—If a bunch of metal is allowed to accumulate at a point in the section of an otherwise symmetrical wall, shrinkage will follow, as a matter of course, and a shrink hole will appear in the section. Shrinkage represents the dimension lost by contraction in metal while cooling; the zone of slower cooling will hold the defect; the section of greatest dimensions will be defective under the circumstances. The sprue, which is the hole through which metal is teemed into the gate of the mould, is usually made to include a "waste piece," to which the sullage will float, and metal will draw from this excess to render the casting solid. In this is an illustration of the point to be made, and in Fig. 9 a boss is shown, the section of which is so great, relative to the main section, that a shrink hole becomes a normal expectation. In the same way a shrink hole will be found in the "lug" that projects like an ear from the bottom flanging, to take the holding-down bolts of the cylinders; if this lug is massive it will have a shrink hole in its section, as depicted in Fig. 10, and the strength of the lug will be reduced very much.

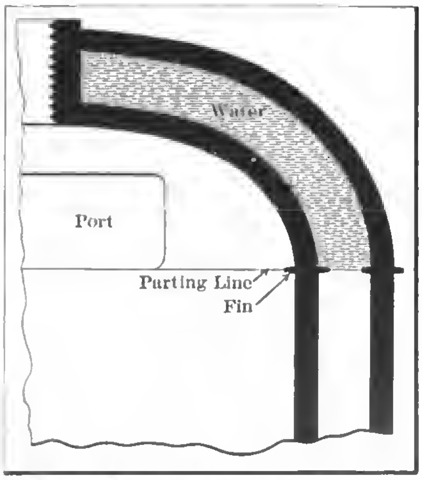

Fig. 7—Fin, at parting line, the product of warped patterns or inferior moulding

As another example of shrink holes, due to the use of fillet work, that is wholly unnecessary, in that the radius of the fillets does not have to be so great, Fig. 11 is offered, in which it will be observed that the shrink hole comes at the junction of the water jacket with the cylinder. This is bad enough, but it is no whit of the difficulty that follows when the shrink hole comes in the junctions of walls of the valve ports, thus offering opportunity for the combustion pressure to leak through into the water jacket, and for water to flood the cylinder on the suction stroke, when the pressure within the cylinder is below atmosphere.

Difficulty Attends Casting Work for Air-Cooled Cylinders—In the pioneer days of the industry, when air-cooled cylinder work was undertaken by foundries of no experience in this line, it was found that nearly all the cylinders were defective, as shown in Fig. 12, owing to the laws of shrinkage, the bunching of metal, due to the presence of ribs or flanges. In one instance the author procured 54 cylinders from a foundry before enough modifications were made to enable the foundry to cast good work. In this undertaking the design was on a par with current practice, and the foundry was accustomed to do good cylinder work, with many hundreds of fine examples to be seen in cars that made a fair record. Despite the favorable circumstances it was found that the castings were defective in every case until after the number of cylinders, as above enumerated, were poured, and as the problem became better understood the results improved, until finally the castings were run off on a better basis, more nearly free from defects.

Fig. 8—Cinder pocket, due to careless foundry work for the most part

Nearly all the defects showed up in the bore of finished cylinders, and in the above example, they were so numerous that it was not possible to consider their use. Even the best cylinders, made of the class in which flanges are integral, do not show a perfectly uniform surface structure, nor is it likely that cylinders, with the ribs cast integral, will ever be as uniform in structure, over the surface of the bore, as will follow in the class of work that includes a uniform thickness of cylinder walls, and other characteristics to match.

Some makers of air-cooled motors, to get away from this, and other casting troubles, follow the practice of applying cooling flanges, after the cylinders are machined in and outside. In this way air-cooled cylinders become very efficient for the purpose, particularly if the flanges are applied so tightly that the joint between them and the cylinder wall is good, from the point of view of the transfer of heat. True, no joint will be as efficient as integral metal; equally true, more flanges can be applied than may be cast integral; the result is that more surface, which is desirable, offsets the slight disadvantage, and this construction has the property of assuring positively good cylinders and enough surface to afford an adequate measure of cooling.

Good Cylinders Are Cast in the Vertical Position—In the old days it was common to see cylinders cast in the horizontal position, with the result that the sullage settled in the barrel, on the top side, and many such cylinders were found to be too defective to sustain in service, thus accounting for the many cylinder failures in automobiles of the earliest time. This same problem was struggled with in the early days of water, and other cast-iron piping, until the practice of casting vertical, in the sand, was adopted; from that time cast-iron piping became a reliable reality. Likewise, in cylinder work, it was found that vertical casting gave the best results, and it is now the accepted practice to so cast them.

In this way, in view of the specific gravity of sullage, which is below that of molten cast iron, the sullage floats to the top, and if a suitable sprue is provided, with gating properly done, all the sullage will be in the "waster" piece; if provision is not made to dispose of the scoria, or other contents that will fall short of quality in the finished casting, it is very prone to settle in the metal, in the region of the valve seats, as shown in Fig. 13; that the sullage will be largely in the surface metal is one of the points that follows logical deductions, and accords with experiences, from the very fact that the sullage is lighter than the body of metal, and is, by the heavier metal, displaced and floated to the surface. In some cases it is the practice to add double "finish" to the valve seats, rather with the expectation that the defective surfaces will be machined away, although, as before stated, it is better to run high sprues and allow the sullage to gate away to a point where it will do no harm.

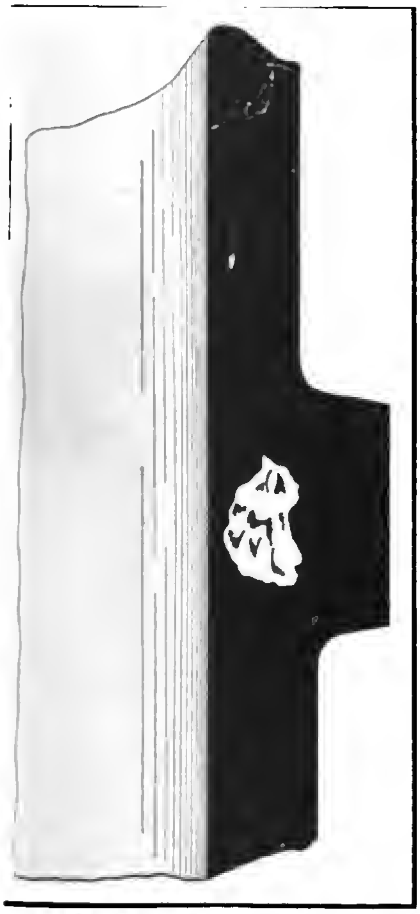

Fig. 9—Section at oil-boss indicating shrink hole due to presence of excess metal in boss

On account of the great importance of having very good metal in the valve seats, it is the practice in some schools of design to provide special metal in the seat, as shown in Fig. 14, by having the valve seat, and its casting, separate from the cylinder casting; with valves in the head, using individual valve housings, the advantage is on the same basis as in the case here shown, excepting that with valves in the head they must be of small diameter, because there is not room enough to make them as large as the standard of practice would seem to dictate. In standard work it is considered that the valves should be in diameter equal to half the diameter of the cylinder, if the speed of the piston is to be 1,000 ft. or over per minute. All valves are not made so large, for the reason that many designers consider that warping is the more prone to happen, and a leaky valve will do more damage, by way of reducing the performance, than will follow if the passageways are a little restricted, as they will be if the valves are smaller.

Ill Effect of Excess Finish In the Bore—Finish is indicated on working drawings by means of the (small) letter f, placed on the line, depicting the boundary of the casting, if it is to be machined on that boundary. In cylinder work, of the class used in automobile motors, it is not the practice to allow for reboring more than once, and the finish is also restricted to the least possible, as fixed by practical considerations, one of which is that the castings much finish up in the bore, because the bore must be free from imperfections. That the surface should be one that will wear well is also a consideration that cannot be overlooked, and in order to be sure of this point, it is the custom to take advantage of the superiority of surface metal, which is somewhat more dense and closer grain than the metal below the surface, as Fig. 15 indicates.

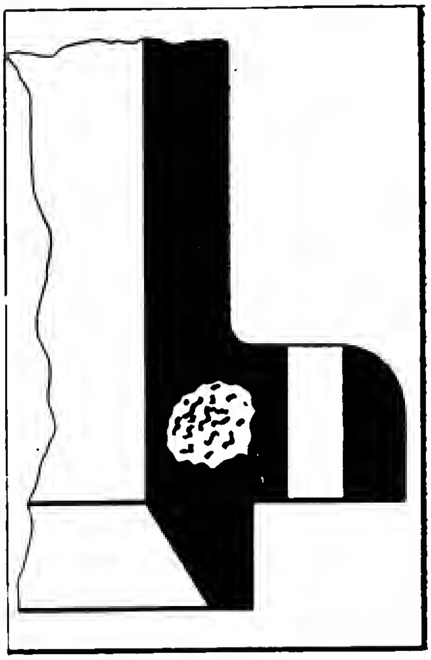

Fig. 10—Shrink hole in section of bolting lug, following presence of excess metal

"Chill," while it is a property that is not wanted in castings that have to be machined, is nevertheless taken advantage of to a slight extent, since chill metal is quite as dense as some grades of steel. In the foundry, when it is desired to have the metal chill to a considerable depth, the proportions of the "charge" in the cupola are adjusted to afford just such results, and chill moulds are used to intensify the result; the moulds are faced with chills, that is to say, facings of iron are used, and since iron has a better heat conductivity than moulding sand, the heat is conducted away from the metal to be chilled, and the result is about the same as if the castings were to be quenched in a quenching bath, as is done to render steel as hard as its characteristics (which is dependent upon the carbon content of the steel) will allow of.

In cylinder work no chills are employed, because it is not desired to render the surface so hard

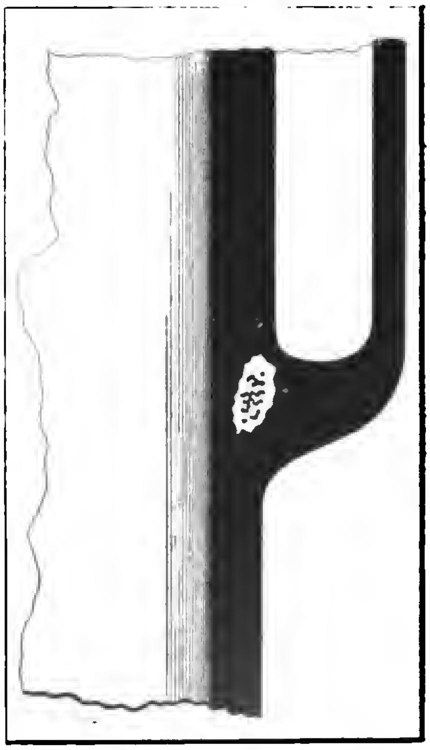

Fig. 11—Imperfection, at junction of water jacket, influenced by use of large fillets

that difficulty will be experienced in machining them; the charge in the cupola is so regulated that the metal in the bore, if excess finish is not allowed, will take on considerable degrees of hardness, under normal conditions, in regular moulds. The amount of finish that should be allowed depends, to a vast extent, upon the quality of the patterns, skill of the moulders, which naturally includes the accuracy of cores, and the core setting as well. If the finish is reduced to 1-16 in. it is barely possible to assure that the surface of the metal, under the finish, will be sufficiently hard to warrant the assumption that a slight chill surface will be present.

The difference between chill iron and the balance of the casting is the difference between gray and white cast iron in a gray iron casting. The gray product is soft and runs high in graphitic carbon, while the white iron is hard and partakes of the qualities of steel to some extent, due to the increased presence of combined carbon. The presence of chills in a mould, while they have the property of quickly cooling the metal as it contacts with the chills, will not result in the same depth of chill of all grades of pig iron, due, among other peculiarities, to alterations in the silicon content; if silicon is high the chill phenomenon will be reduced.

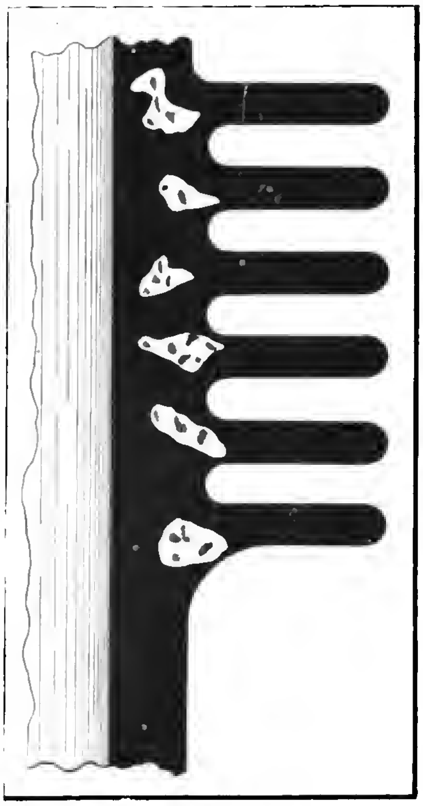

Fig. 12—Defects, characteristic of cylinders, of the air-cooled variety

That a perfectly symmetrical shape is of the greatest advantage is found to be true, and since it is desired to have the least possible surface between the combustion chamber and the cooling medium, a shape that will give the least surface should be selected. A semi-sphere affords the least surface, and is frequently selected for the dome of motor cylinders on that account.

Before going into this phase of the subject, however, it is important to point out that cylinders are made with integral heads, for the most part on account of the difficulty experienced in packing joints when they are in the great heat and expansion changes that are normal to automobiles. It has been found that no form of packing will stay tight for any length of time, and even when joints are "ground" they are prone to leak in the course of events. It must be remembered that the pressure is high—varies from below atmospheric to the maximum at a sharp rate —and is attended by rapid heat changes which accentuate the tendency. If the holding bolts are separated any considerable distance the castings are likely to deform enough to leak compression, and destroy the good working of the motor. In some cases it was found that long holding bolts would stretch enough to allow the head to raise off the cylinder and the compression would leak out in this way; this form of trouble was extremely difficult to detect, since the head would be perfectly tight with the cylinder cold, and the leakage would be momentary, due to expansion of the bolts from heat and pressure. In some examples of twin cylinders, with very thin walls between them, especially with soft and porous metal, leakage develops between the cylinders, and the greatest difficulty, due to this defect, lies in the transfer of the products of combustion from one cylinder to the other, thus destroying the advantage derived from complete scavenging. This trouble is avoided in some designs by having a gap between the cylinders, so that the walls are not common to both of them, and while the space required is increased, the plan has the advantage of absolutely defeating trouble of this sort.

In cylinder casting work, in view of the main requirements, it is not desired to have the chill properties too prominent, and in order to have a facing of white iron over the gray iron core, it is necessary to fix the finish accordingly, which is merely a question of resisting the same, and making up for this restriction by doing fine work in the patterns, to begin with, and in the foundry for the rest.

Quality of Cylinders Depends Upon Co-operation — From what has been said it may be inferred that the quality that must reside in cylinder castings, if they are to excel, depends upon the co-operation of the pattern maker, the foundryman and the machine shop artisan. Each will be able to thwart the other in any attempt to evolve quality, but good foundry iron must be settled upon concurrent with the use of mahogany for patterns, and certain degrees of "horse sense" in the shop. No matter how competent the designer may be, if he is not supported in all departments, the purchaser of the car, and the shareholders of the maker will have to face loss.

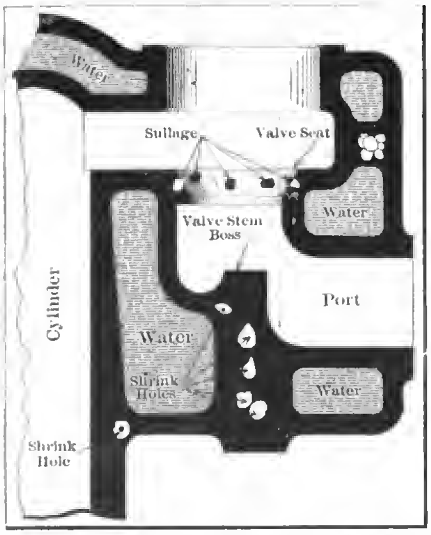

Fig. 13—Sullage renders valve-seats defective when the cylinders are cast vertical, and carelessly done

From the point of view of the designer, in the process of evolving good cylinders, it is necessary to determine as to the compression that will afford the best results; then, the shape of the cylinder is important, in that the mean effective pressure will depend upon the shape, as well as upon the ratio of clearance to displacement volume.

Cylinders cast en bloc, to be used in motors of the class having crankshafts with but two bearings, must be as short as possible to favor the crankshaft, and in such cases it is the practice to make common use of the separating walls of the cylinders: in such cases, trouble is guarded against by the proper "venting" of the moulds, which is possible owing to the method of using separate covers for the water-jacket, thus affording good venting for the gases to escape, and assuring close metal with freedom from attending troubles of the character above named.

(To be Continued.)

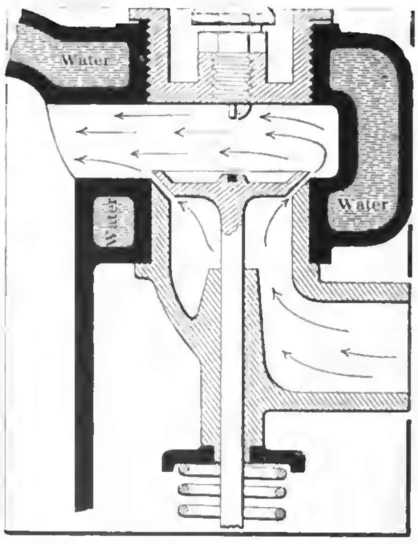

Fig. 14—Separate valve housings afford an opportunity to use superior metal in valve seats

A Constant Pressure Engine

By Morris A. Hall

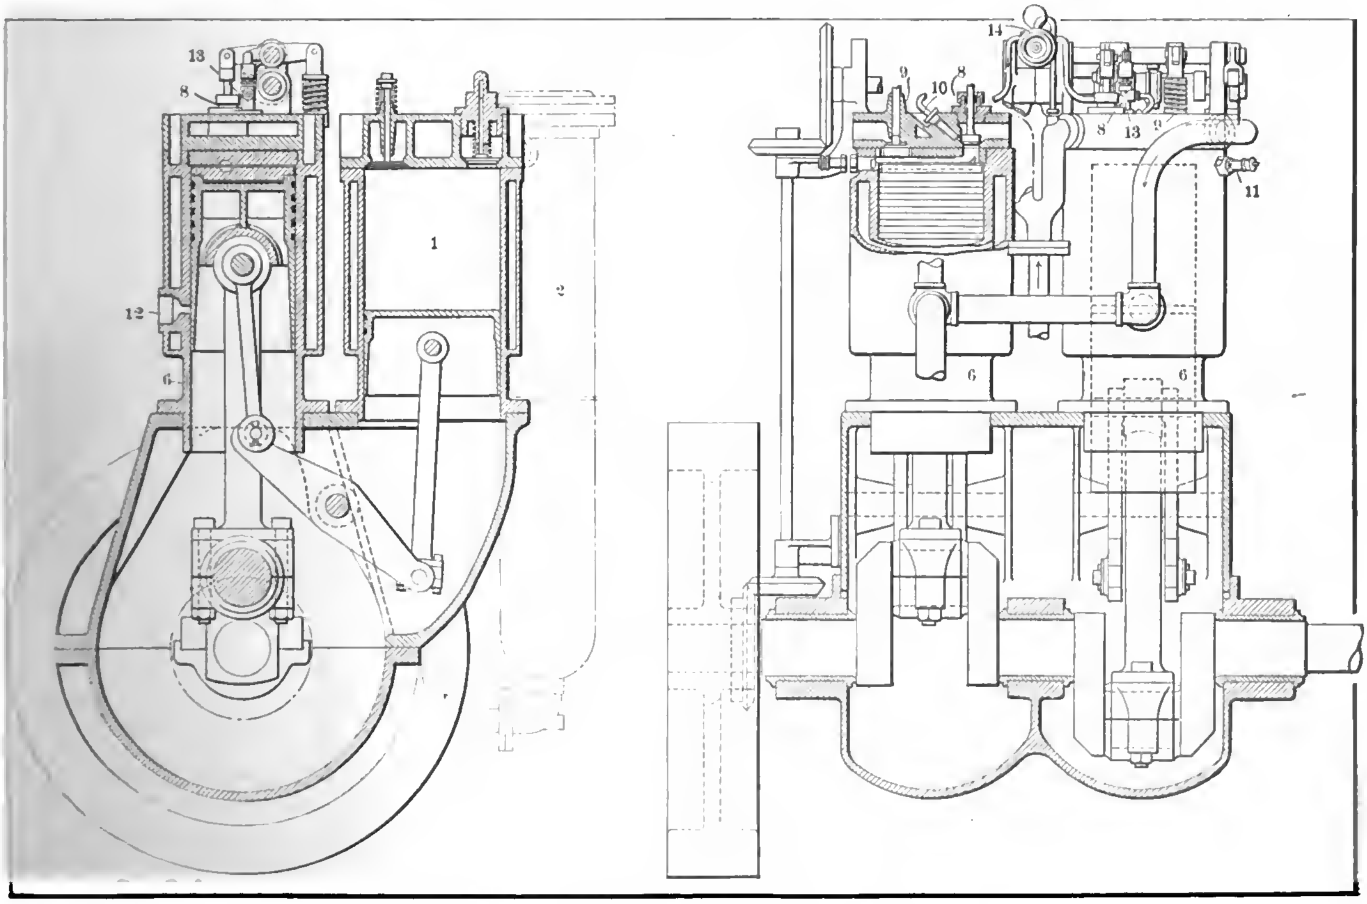
WHEN Brayton brought out his constant pressure engine in 1873, he did so at an unfortunate time, for just then the Otto cycle engine was beginning to come into its own. The simplicity of this, coupled with the additional complications of the Brayton engine, particularly noticeable in small powers such as were usual at that time, did much to discount the Philadelphian's invention, although theoretically it had much to commend it, and the machines built and operated then were unusually successful.

In as much as some work is being done now upon engines of the Brayton type, one having been brought out very recently, a short mention of the principle upon which the type works, and of the particular features which distinguish it from the ordinary gasoline engine, is well worth space.

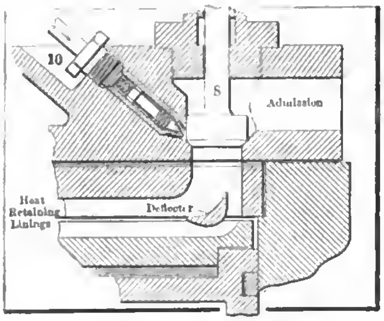
First, as to the history, Brayton was a Philadelphian, who invented and constructed an engine in 1873. This was exhibited at the Centennial in 1876. The foreign rights to the invention were purchased by Messrs. Simon, of Nottingham, England, who constructed a machine along the same lines, but differing somewhat in detail. A Simon-Brayton engine was exhibited by the English firm at the Paris exhibition of 1878, and attracted much attention. The additions made by the Messrs. Simon were not very successful, in fact their engines did not perform as successfully as did the original. One year later, a German firm, Hennig & Company, brought out an engine of this type, under license from the Simons, but this also was not very successful, due to the fact that Germany had then taken up with the Otto form, going in for it very extensively. So, the more complicated constant pressure machine could hardly get a hearing. Probably the last attempt of that period was made by a Scotchman, Foulis, of Glasgow, who brought out his motor in 1881, although his patent was dated some three years previous to this. Like its English and German prototypes, this was shortlived.

Diesel Shows Some Similarity—The German Diesel engine shows a marked similarity to these, in that it operates at a constant temperature and theoretically it comes in the same class. But Diesel introduces his fuel in the form of a spray, projected into a highly compressed mass of pure air, the temperature of the latter being such as to ignite the fuel instantly. The compression of the air is an adiabatic change, and the fuel is so sprayed in as to maintain a constant pressure. This continues up to the point of cut-off, whereupon a decrease in pressure with a corresponding rise in volume takes place, this being adiabatic expansion. It is said that this cycle does not approach the true Carnot heat cycle as closely as would an engine in which the operation proceeded along constant pressure lines rather than constant temperature. That is to say, that although the Diesel motor has up to date shown the greatest efficiency of any known internal combustion engine, its possibilities are far below that of the engine operating at constant volume. On the score of efficiency then, the Brayton may be considered as of a much higher type than the Diesel.

The working cycle of an engine of the Brayton type consists of five operations. These are:



Section and Elevation of Stilz Constant Pressure Internal Combustion Engine



Detail of Admission Valve

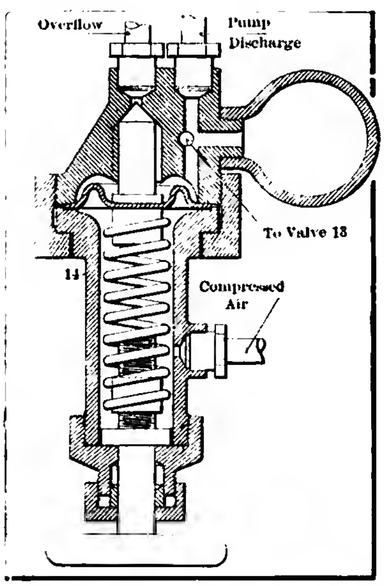
1. Charging the pump cylinder with gas and air mixtures.
2. Compressing the charge into an intermediate receiver.
3. Admitting charge to expansion cylinder in the state of flame, at the pressure of compression.
4. Expanding after admission.
5. Expelling the burned gases from cylinder.

All of these requirements are well within the range of the possible, but to carry out the cycle in an efficient manner a number of conditions will have to be fulfilled. Some of these are: there should be no throttling during admission of the charge to the pump; no heating of the charge as it enters the pump from the atmosphere; no loss of compression to the pump and receiver walls or within the latter; no throttling of the charge as it enters the motor cylinder from the receiver; no loss of heat by the flame to the sides of the motor cylinder and piston; no back pressure during the exhaust stroke, and the latter must be very complete, that is. the working cylinder should have no clearance. This last, however, is but a mechanical detail of construction, easily attained.

Newest Constructor a Philadelphia Man, Too—The newest constructor along the lines as laid down by Brayton thirty-five years ago, is also a Philadelphian, H. B. Stilz, by name. Stilz has built and operated several engines for widely differing purposes, having gone far enough in each case to prove his design a markedly successful one. The engine possesses a number of modifications over that of Brayton or any of his contemporaries, and all of these are by way of improvements tending to make the resulting product more efficient, in the light of thirty years progress.

In this engine, the compression being more or less isothermally that of cool air, is accomplished with less work (than in the Diesel type) and without any great temperature rise. The cool compressed air absorbs more than enough heat from the exhaust gases to balance the cooling loss in the compressing outfit and thus the engine gains by the difference in the work of cool and hot compression. This saving, though small, is in the nature of a recovery from the exhaust and therefore indirectly a source of power.

Stilz scores again in the compression, for a specific weight of air is a necessity, which with hot compression involves pumping a much greater volume at the same pressure, due to the natural expansion under heating and consequent loss of volume. This additional pumping means more power and is a direct loss. What heating or expansion may take place in the Stilz engine does so at the expense of the exhaust, a loss anyhow, so that no actual loss is sustained.

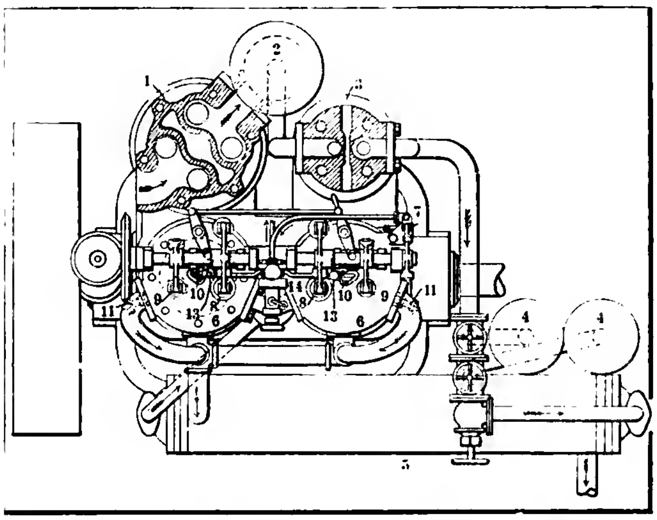


Construction of Fuel Regulator

Possibilities for Improvement—It may readily be proven that the heat efficiency of any internal combustion engine is increased by compressing the working medium with the least possible rise in temperature so as to make possible the greatest recovery of heat from the exhaust, and by securing complete combustion at a constant pressure. In so far as this presents in a concise form the points sought after by both the Brayton and Stilz designs, it is fair to say that the latter has but to prove that he obtains them, to secure the recognition awaiting a genius, who succeeded where others failed.

Only time and continued tests can prove these points but a description of the engine will show if the device is such as to bring them within the range of possibilities.

The engine shown is of a type suitable for automobile or marine use, but the first engine built by Stilz, and even now running successfully, was of a more substantial type intended for stationary use. This was somewhat larger than the one shown, having a single power cylinder 5½ inches in diameter by 7 1-2-inch stroke, single acting, but receiving an impulse every stroke, thus being comparable with a two-cycle engine. The low pressure cylinder was 4 1-8 inch by 6 inch working double acting and driven from the main shaft, this being like a two-cylinder crankshaft with cranks at 180 degrees. The high pressure cylinder was much smaller with a bore of 2 1-8 inch and



As Stilz Engine Appears from Above, Partly in Section

a stroke of 6 inches. This was driven by an extension of the piston rod of the low pressure cylinder worked single acting.

Details of the Automobile Type—Coming next to the design of a lighter model suitable for automobile work, many changes from the stationary type are found. As shown in the large sectional views and the top or plan view, two power cylinders are used. These are supplied with fuel by a system of cylinders, tanks and piping, which includes a low-pressure cylinder marked 1, the piston of which is driven from one end of a lever, pivoted on the crankcase partition wall, the other end being reciprocated by a second lever attached to the piston pin of the power cylinder. The high-pressure cylinder marked 3 is operated in a similar manner from the other piston pin.

The engine operates upon oil as follows: air is drawn into the low-pressure cylinder (1), and after compression there, passes into the intermediate receiver and cooler (2), from which it is further compressed in the high-pressure cylinder (3). It is then delivered into the compressed air system, into which two receivers (4) are connected so as to furnish a means of starting the engine under load, as well as helping to carry overloads. Normally, these are, or may be, cut out by the valves shown. In running condition, the air passes from the high pressure cylinder to the exhaust gas heater and muffler (5). From the heater, the warmed air is admitted to the two power cylinders (6) alternately first to one and then to the other.

Oil is delivered from the oil pump (7) of the plunger type, driven from the overhead camshaft, into the pressure regulator

(14), shown also in an enlarged view. This regulator has a flexible diaphragm at the center of which is connected a spring, located in a chamber to which the air has access at its highest pressure. To the other side of the diaphragm is attached a valve, situated in the space connected to the oil pump delivery pipe. The combined pressure of the compressed air and the spring tends to keep the valve seated, so that no oil flows. But when the oil pressure exceeds the other pressures combined (the hand wheel allows of adjusting this to the correct amount) the action of the diaphragm lifts the valve off of its seat and allows oil to escape. Under ordinary conditions, the oil flows through the valve (13) which opens simultaneously with valve (8) operated from the camshaft. Passing through the valve to the pipe (10) the oil is given a rotary motion which breaks it into a fine spray. This causes it to be uniformly mixed with the air charge, which enters at the same time through valve (8). Entering the combustion space thus, the combined air and fuel charge is deflected toward the igniters (11) by the deflector plates placed in the cylinder head for that purpose. The ignition may be of any kind, although that shown was supposed to be of the regular jump spark type. After combustion, the burned gases are exhausted through the mechanically operated valves (9) and the auxiliary ports (12). A minor improvement consists in so shaping the cams as to change the period of valve opening by shifting the camshaft longitudinally. The speed of the engine may be controlled in this manner.

Principal among the advantages claimed for this style of engine are flexibility approaching that of the steam engine, highest efficiency, impossibility of preignition and consequent backfiring, more uniform turning effort brought about by the elimination of explosions, positive control, compactness, light weight and extended possibilities for the use of many and varied fuels other than the ordinary gasoline and the fuel oil used in this particular engine.

NEW TYPE OF FRANKLIN AIR-COOLED ENGINE

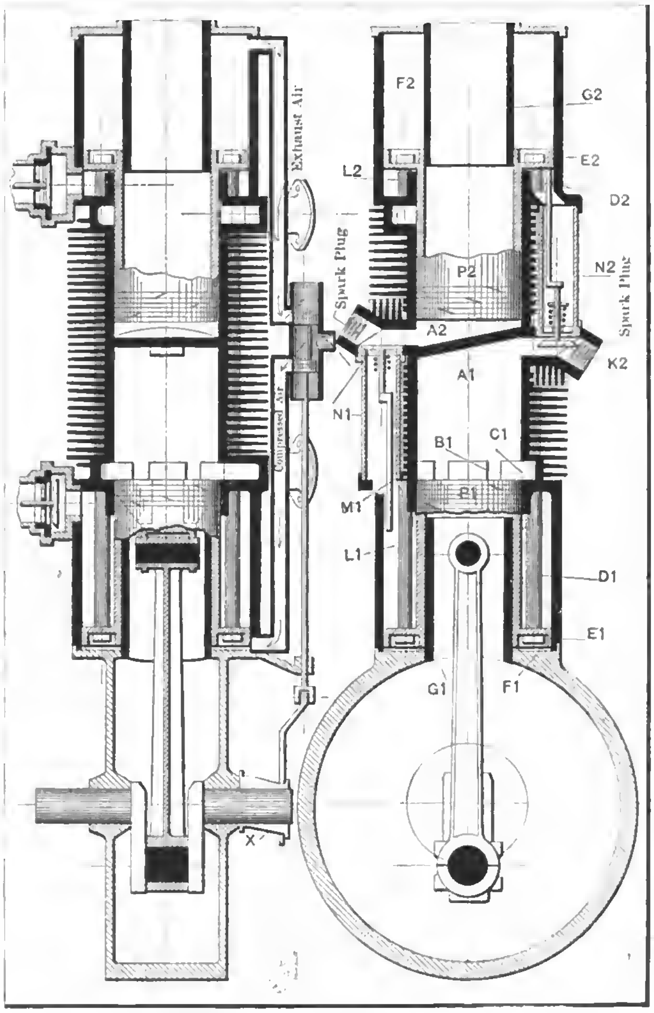
AFTER six years of experimentation and construction, Ernest Franklin, Portland, Ore., has succeeded in building and operating an engine for automobiles and motor boats, which has a number of remarkable and very prominent features. Mr. Franklin's first field of experiment was the double-acting engine, but after long research in this line, he became discouraged with the results and turned to the two-cycle type.

His latest production, shown in the illustration, is of the differential piston type of two-cycle motors, but has this radical departure from current practice: the cylinder is open ended and has within it two pistons. These are connected together by means of tie rods, and actuate a single crank. The engine is cooled by means of air, thus doing away with the troublesome water, piping, and pump.

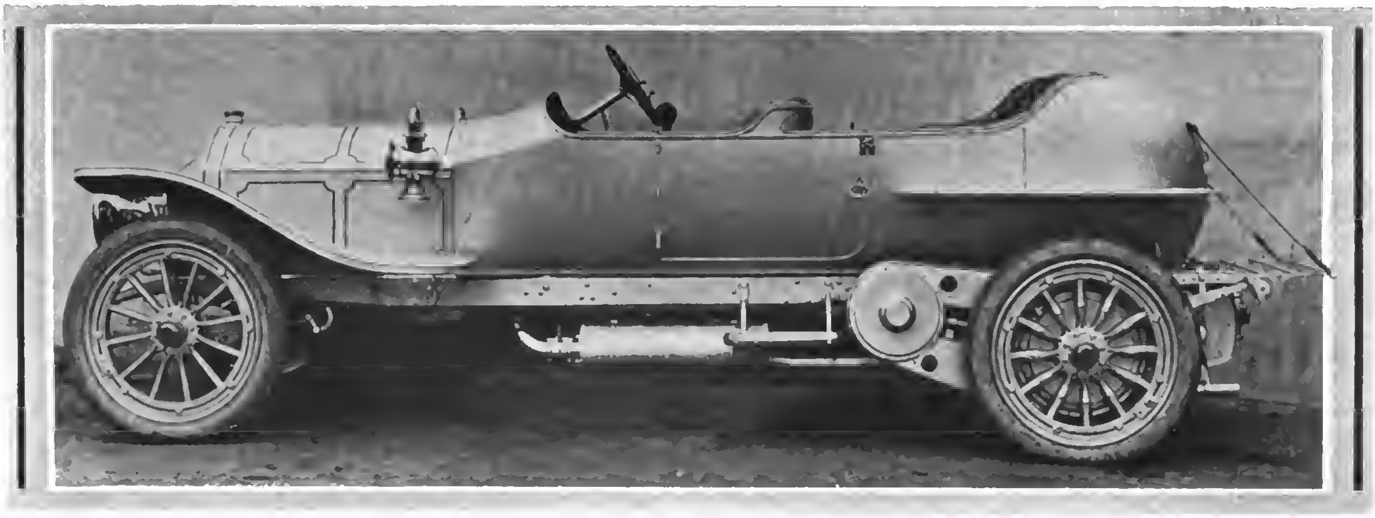
As might be expected with an engine of this type, the explosions take place in the middle of the cylinder, where a partition is thrown across to divide the two and answer as a cylinder head. The charge is drawn in at the extremities of the two pistons of larger diameter. These compress it and deliver to the working pistons of smaller diameter, the upper one feeding the lower working piston while the lower furnishes the fuel to the upper piston. By an ingenious arrangement, camshafts are dispensed with and all valves are either operated by suction as in the case of the fuel inlet valves or are actuated from some other part of the engine as in the case of the admission of the compressed fuel from the differential piston to the working piston. This is done by the piston itself, which at the limit of its stroke opens a valve leading into the smaller cylinder.

In addition to being air cooled, two-cycle, differential, two piston, this engine is self starting, that is, in the design provision was made for starting by compressed air. The sliding piston valve seen in the right side of the first section controls this. Air being admitted at that point, will pass up or down the jacket provided for that purpose, to the piston which is properly placed, and thus, turn the engine over. The piston valve just spoken of is connected with the crankshaft and in that way directs which piston will receive the compressed air.

All of the parts are marked with subscripts, the ones above the center being marked 2 and the lower ones 1. The pistons are P_1 and P_2, and are connected by the tie rods D_1, D_2, which pass through bushings in the cylinder casting. The extensions of the pistons work in the larger bore, and convert the chambers L_1 and L_2 into compression spaces, L_1 supplying piston P_2 and L_2, P_1. The former works through the transfer port N_1 and the valve K_1. The exhaust ports are cut right through the walls of the cylinder at C_1 for the lower piston. The sleeves G_1 and G_2, shown in solid black, are said by the inventor to be placed in the cylinder for the sole purpose of allowing the compressed air starting arrangement to work. Be that as it may, as shown in the working drawing of this engine, they are of such a small diameter that the connecting rods can only oscillate about 20 degrees each side of the center and cannot make a full revolution. A mere trifle like that should not worry a real inventor, however. Mr. Franklin states that he is now working on a two-cylinder engine with cylinders set at 90 degrees to each other, and working on a single crank, which he says would give four explosions per revolution and thus be equal to a regular eight-cylinder four-cycle engine.



Franklin Air-Cooled Two-Cycle Differential Piston Engine



A English Idea of the New Torpedc Body, on 60-Horsepower Mercedes Chassis

BODY BUILDERS NOW EXERCISING MUCH INGENUITY

SPURRED on by the continuous calls for something new, different, or original in the line of coach work, Continental and English body builders have now gone far into a new line of body types. These are so radically different that with regards to them, all automobiling people at once line up in one of two classes—either the newest bodies are about the best thing ever, or else they are by far the most homely, not to say ugly, specimens of coach work ever produced by intelligent men.

Starting some years ago with the so-called Napier "bath tubs," bodies have followed a general tendency to length, and lack of height, giving a low, rakish appearance. Following in this same line came the side doors to the front seats, brought out last year, which attained much popularity.

Then, at the time of last year's Prince Henry trials, Germany took the lead with the dust-proof rear construction, from which the now popular name for this type, the torpedo body, came. Although the body shown on a Mercedes chassis is of home make, the idea is exactly the same as the German builders expressed in their work. While looking very peculiar, appearance alone had little to do with the shape, which was evolved as a solution of the dust problem. The idea in this was to prevent the suction of dust at the rear which obtains with any body having flat space at the rear, whether vertical, horizontal or inclined. Moreover, this shape does not concentrate its claim to usefulness in the one item, but possesses many meritorious features.

Bulging Rear a Veritable Storehouse—Chief among these are the utilization of the huge and unusual bulge at the rear as a storage place for tools and sundries. In actual capacity this is a veritable storehouse, as there is untold room here for tools, spare parts, extra garments, and luggage of all sorts. As the rear view with the doors open shows, the storage space is very large.

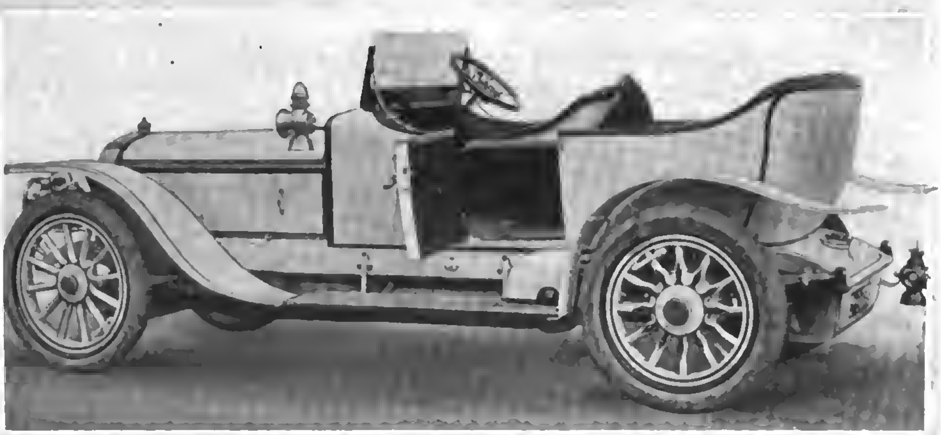
In addition to making the rear of the car dustless, so that in dry weather the tonneau is more comfortable even than the front seats, this construction allows of the practical removal of the rear fenders, with consequent improvement in the whole appearance. This car body was probably the first to appear with the single entrance to both tonneau and front seats, one long side door answering for both.

In this epochal body, too, appeared for the first time the flush sides as complemental to the dust-proof feature. It meant reducing the capacity of the car or else a tremendous wheel base, because the large tonneau capacity could only be obtained with bulging sides. The reduced capacity was well received, and many subsequent bodies have incorporated the flush sides until they have become quite general.

Many English Firms Fell Into Line—Quite taken with the natty and rakish lines obtained in this manner, many of the more prominent firms fell into line, notably Napier, Austin, Gregoire-Gordon, Brown, Arrol-Johnston, and others. Several styles of bodies by Austin's body builder are shown. In these it will be noticed that all do not agree. The large 100 horsepower chassis is fitted with a body creation along Mercedes lines, including the single side door opening toward the front. There are several noteworthy differences. Among them the most prominent is the substitution of the full rotund back shape in place of the extreme torpedo shape, although even this body comes under the new classification of torpedo. With the elimination of the globular stern will be noticed the return to the use of rear fenders.

Rear View, Showing How the Space Is Utilized

The earlier Mercedes bodies with the single side entrance had the left-hand front seat attached to the door, so that it rotated out over the step when the door was opened. In late models, as for instance the one shown, this is changed, and the door is so located as to straddle the length of the front seat, allowing entrance to the front, forward of it, and to the tonneau, back of it. The Austin provision differs from this and consists of tipping the left-hand front seat, it being back



Inclined More to the Rotund Curve with Straight Lines, 100-H.P. Austin

of the right-hand or driver's seat enough to allow the back of it in tipping to clear the back of the stationary driver's seat.

This particular car is one of the six-cylinder Austins that ran in the last Grand Prix race. Unlike the Mercedes body, which is of aluminum, this is made from selected woods.

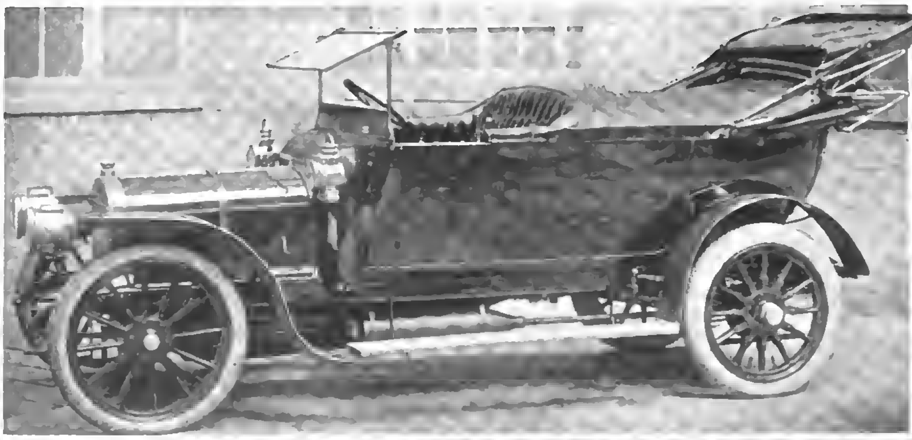
Builds Also for White Steamers—The straight-line torpedo body on the smaller Austin is a product of Cann & Co., the London firm that builds the bodies for White steam cars over here. This little Austin has a four-cylinder engine rated at 18-24, with cylinders of 105 mm. bore by 127 mm. stroke. This body, it will be noticed, differs from the larger one, in that two side doors are used, although the straight lines in the side view are the same, as is also the rotund curve at the rear. The very narrow front door is placed close up to the dashboard and opens forward. The rear door, on the contrary, is very well placed, is very wide and commodious, and opens toward the rear. The fenders, too, are different. On the little Austin, the step is carried lower down to accentuate the low and long appearance and offset the short look which the wheel base of but 115 inches would otherwise give. To aid in this deception, both front and rear fenders are carried down with a sharp dip, the fronts at the rear end and the rears at the front end. While the whole effect is very much on the straight-line order every opportunity is seized to depart from this. It can be noticed in the deep curving dashboard, in both front and rear doors at the lower back edges, in the long fender sweeps, and elsewhere on the sides of the body.

Extreme Only in Appearance, Not in Dimensions—In all of the bodies shown, there has been a sensible compromise between the extremely high and equally uncomfortable seats of several years ago and the very low, undignified "couches" of more recent times. The latter, in some cases, went as low as 8 or 9 in. above the floor of the body, with the seat backs not over 18 to 20 in. total height. With these went the long leg room, which, coupled with the low seats, gave the body its long, low appearance. This increased and increased until it passed 36 in. In the torpedo types, the latter feature has been retained, but without extremes, a distance of 34 in. from seat to dashboard predominating. So, too, with the height of seats, the very low position, not being necessary to further the body lines, has been abandoned in favor of a more sensible, more dignified height. Probably most of these torpedo bodies upon detailed examination would be found to have not far from 12 in. from the top of the front seat cushion to the floor, this being increased to 14 in. in the tonneau.

Of the two styles of torpedoes brought out thus far, it would seem as if the rotund rear with straight line flush sides would be likely to meet with more favor than the globular shape, because the latter borders more on the extreme, although both savor of the shops, so up-to-date are they, or up-to-the-minute stated in more correct language.

In all probability the future will bring out more and varied torpedo bodies, offering new suggestions, and doubtless many of them will bring forth additional ideas on the subject of dustlessness, as incorporated in the shape and proportion of the body, not only at the rear, but along the sides and underneath the body proper as well.

New Little Mercedes Similarly Equipped—The latest production of the famous Daimler works differs very markedly from its predecessors in mechanical construction, but is equipped with the now-famous torpedo shaped body. This new car has a small engine with an unusually long stroke, in which are shown the effects of the numerous competitions of the past year in which the stroke was unlimited. The motor is of 80 mm. (3⅛ in.) bore by 130 mm. (5⅛ in.) stroke and is rated at 15-20 horsepower. With the unusually long stroke, a ratio of 1 to 1.625, the power developed would be far in excess of even the higher rating. To this is fitted a flush sided body of the torpedo type, but with many differences from that of the larger and more powerful chassis. The elimination of the chain for driving and the substitution of shaft drive, changes the whole rear construction and also calls for rear fenders. This practically makes the front fender a necessity, and with both in use, the step is natural, while on the larger car, the practical elimination of both fenders made the use of the step superfluous. On the little car, too, the use of the two doors is at once noticeable. The rear is very similar to that ordinarily fitted to a short tonneau and opens to the rear in approved style. But the front door, on the other hand, is very narrow, very high in proportion to its width, and opens to the front. On the driver's side of the car, hinges are dispensed with and the door slides upward, being pulled clear up and out for admission on that side. The prolonged dash peculiar to all torpedo bodies is retained, while the body door, molding and other curves take away the very straight line.



18-24-H.P. Austin with Same Style of Torpedo Body, But Two Side Doors

LETTERS INTERESTING AND INSTRUCTIVE

NEW FRONT DRIVE SCHEME

Editor THE AUTOMOBILE:

[1,934]—While looking over the copy of the June 10 issue of "The Automobile," I could see no reason why the front drive need be so compactly or complicatedly built, so am sending you a sketch of an idea of mine for a front drive which is not so complicated. R. T. PALMER.
Hampton, Va.

The sketch is shown elsewhere on this page and differs from other front drives only in that the engine is set in the standard and stereotyped position at the front and parallel to the axis of the car. Back of this is the transmission, which carries on the left side a pair of bevel gears. By means of these and a shaft drive back to the front axle, the power is transmitted. In this form of drive the power is transmitted from front to back and then from back to front again. What possible advantage there can be in this "gun-shoot-around-a-corner" scheme, only the inventor can see. A more reasonable method, if it is not desired to place the engine across the car, is to place the engine at the back and drive forward continuously from engine to transmission, to front anxle.

The disadvantage of this is accessibility, which also applies to the design shown on the sketch. The transmission is under the body where it is very inaccessible. Also, the arrangement of the driving shaft would have to be such as to allow the front axle and shaft to rotate around the bevel, when the front wheels surmount an obstacle.

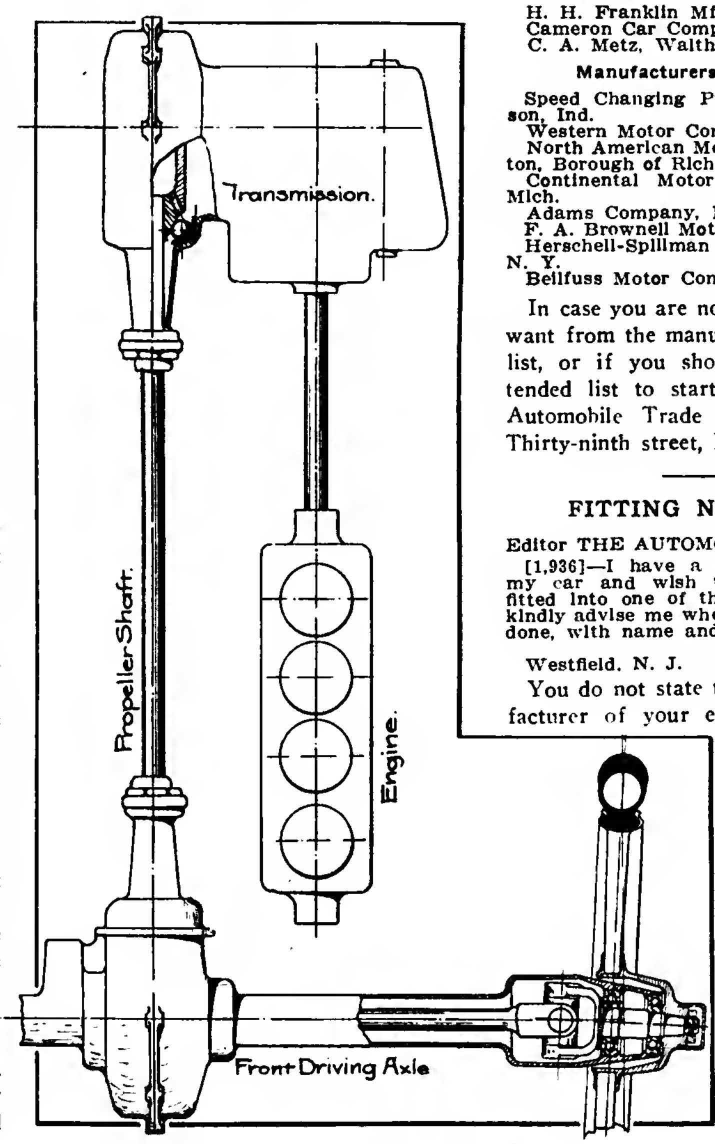
A disadvantage of this scheme, which the inventor has overlooked, is the fact that if the engine is placed in the center of the frame, the drive will have to be off center. Or, if the drive is set central, the engine will have to be off center. An equally weighty argument against this form of drive lies in the fact that at least three pairs of bevels will have to be used, and these are objectionable for they consume more power than do spur gears.

Since we are going into the disadvantages of the proposed scheme, it will be well to mention all of them. Thus, the center of the car location of the transmission will take just that much weight off the driving wheels. As weight means traction, this is an apparent disadvantage.

In his remarks about the compactness and complicated appearance of the front driving scheme of Christie, the father of this suggestion missed the point. The cab described does not have to have the compact drive as shown; in fact, this could have been worked out in a number of other ways, all possessing some merit. But this design was made special for a special service, and as such it has very much merit. If Mr. Palmer will reread the description, he will see on page 953, the situation is summed up as follows:

There is, however, a secondary advantage, which is alone and of itself amply sufficient to call for serious consideration of motor cab front driving and steering. This is the possibility of a front motive and steering assembly of small dimensions, entirely self-contained and very readily detachable from the remainder of the chassis and car body assembly.

This means that with one extra fore-carriage for, say, every ten cabs, the whole ten can be always kept in working condition with only the one small fore-carriage assembly in the repair shop, and all ten of the bodies and rear wheels assemblies out on the street earning money. With the rear wheel drive any failure back of the motor puts the whole car on the sick list, if, indeed, the motor is so constructed as to be readily removed from the car.



Palmer Front Drive with Motor in Regular Position

SMALL AIR-COOLED ENGINE

Editor THE AUTOMOBILE:

[1,935]—Could you inform me where I could purchase a four-cylinder air-cooled motor of about ten or twelve horsepower and suitable for a midget automobile? LEON PELLET.
Dallas, Texas.

The size of engine which you require is so small that we are unable to call to mind any firm making it. According to the A. L. A. M. rating formula an engine of 4-cylinder, 2¾ in. in diameter would be rated at 12.1 horsepower, and one of 2½-in. bore would rate at 10 horsepower. These are very small sizes. However, we are giving below a list of car and engine builders, most of whom build some small-sized air-cooled engines. It is possible that the car manufacturers would not care to sell you an engine, but you can only try them and find out. The list follows:

Manufacturers of Complete Cars.

H. H. Franklin Mfg. Co., Syracuse, N. Y.
Cameron Car Company, Beverly, Mass.
C. A. Metz, Waltham, Mass.

Manufacturers of Motors Only.

Speed Changing Pulley Company, Anderson, Ind.
Western Motor Company, Logansport, Ind.
North American Motor Corporation, Stapleton, Borough of Richmond, New York City.
Continental Motor Mfg. Co., Muskegon. Mich.
Adams Company, Dubuque, Iowa.
F. A. Brownell Motor Co., Rochester, N. Y.
Herschell-Spillman Co., N. Tonawanda, N. Y.
Bellfuss Motor Company, Lansing, Mich.

In case you are not able to get what you want from the manufacturers on the above list, or if you should want a more extended list to start with, write to "The Automobile Trade Directory," 231 West Thirty-ninth street, New York City.

FITTING NEW PISTONS

Editor THE AUTOMOBILE:

[1,936]—I have a two-cylinder engine in my car and wish to have a new piston fitted into one of the cylinders. Will you kindly advise me where I can have the same done, with name and address of firm? WM. EHMLING.
Westfield, N. J.

You do not state the name of the manufacturer of your engine or car else we would refer you to the makers, who are the best ones to do the work, as they will doubtless have pistons of this type on hand which will go right into place. If you have to have this work done in an ordinary machine shop it will cost you a lot of money, because it will be necessary for them to measure up your piston, have a pattern made, get a casting from this, machine it up like the other piston, then balance the old and new ones exactly alike, and finally fit the new piston into the cylinder.

We might give you the name and address of a number of firms near you which would do the work, and do it well, but in view of the great expense connected with this method of procedure, as outlined above, it would be better to look for the name of the maker and go to him.

In default of finding this, or in the case that the car is an assembled one, it would be well to go to an automobile factory near you, as it might happen that they had a piston which was near enough to yours so that a good finished product could be produced from their casting. This would save you the first expense of measuring up your piston and making a pattern.

SELF-STARTING MAGNETOS

Editor THE AUTOMOBILE:

[1,937]—In the June 10 issue of "The Automobile" in "Letters Interesting and Instructive" I note in answer to letter 1,908 that you state there are several magneto manufacturers who are putting out devices tending to start the engine by producing a spark, this being done by rotating the magneto armature. Will you kindly give me the names of these manufacturers, as I am interested in this and anxious to get in touch with them? E. J. WARING.

Providence, R. I.

As to starting devices, you will find out much about these by simply reading over the pages of THE AUTOMOBILE, something on this order being published every little while. Descriptions of devices of this sort have appeared in recent issues, as follows:

December 17 issue, pages 859 to 860.
January 7 issue, page 25.
January 7 issue, page 26.
March 18 issue, page 486.
June 3 issue, page 927.

and, finally, if the subject of starting interests you, an excellent article on this subject headed "Self Starting Devices Attract Much Attention," by Morris A. Hall, appeared in the April 1 issue. This dealt more particularly with the mechanical than with the electrical schemes for starting the engine.

VALVE STEM SIZES

Editor THE AUTOMOBILE:

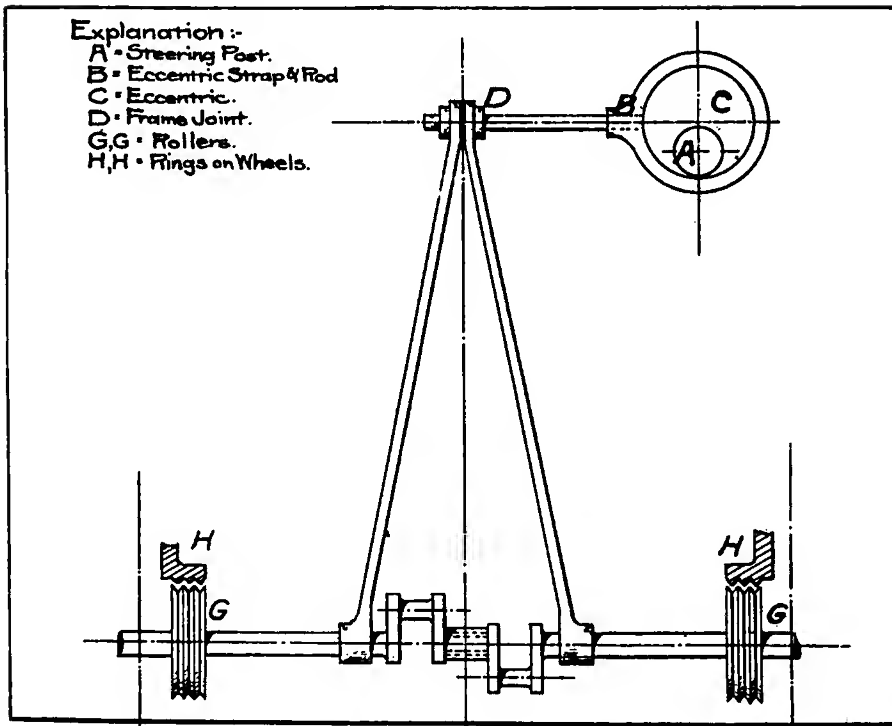
[1,938]—Having seen a number of empirical formulas given in "Letters Interesting and Instructive," I write to ask you to give me one for proportioning valve stem diameters. SAM MANNHEIM.

New York City.

While we deprecate the use of empirical formulæ for parts which may be calculated, you will find the formula desired below. Valve stems may be figured on the basis of any good column formula, taking into account the load on the head of the valve. A very nice looking valve stem will result, however, from the use of the formula:

$$D = \frac{d}{5}$$

In which D is the desired valve stem diameter; d is the clear diameter of the valve.



Sketch of Duryea Differential Showing Operative Mechanism

DIFFERENTIAL INTERESTING

Editor THE AUTOMOBILE:

[1,939]—Your reply to number 1,892 in "Letters Interesting and Instructive" about eliminating the differential and your remarks about the Gould patent in the June 3 issue of "The Automobile" are along right lines of thought and lead me to believe that you will appreciate a description of the Buggyaut scheme for getting around a corner. I send photo of the chassis and diagram of the substitute for a differential. In the chassis the two central bars running from below the cylinder heads to the support at the front are part of the engine and power plant frame. This power plant is hung to the side bars at one point on each side and these bars are supported at the third point front. This makes a three point support to the three pointed power plant. The driving rollers are at the rear points. The front point can be shifted sidewise. If shifted to the right it will throw the right roller to the rear. Or vice versa. A very little movement is sufficient to release the metal to metal contact between the rings and rollers.

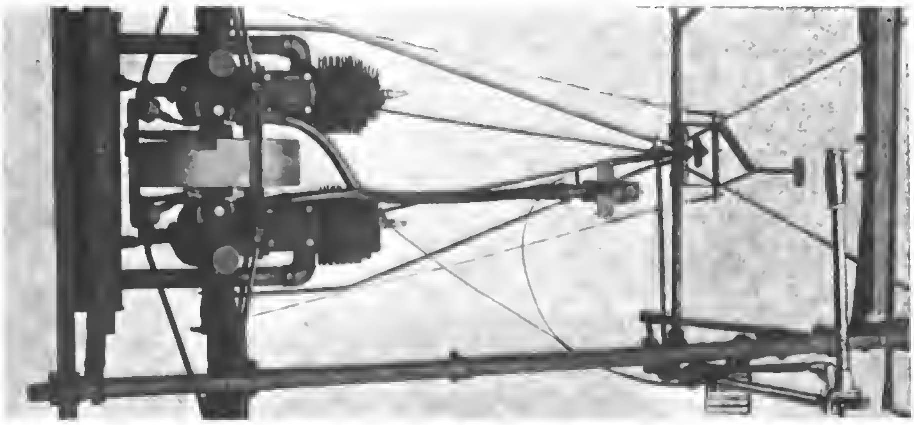
On the steering post is an eccentric. Its center is forward of the center of the post. It is surrounded by a strap and has a rod running to the front point of the power plant. Adjusting nuts are provided so the rollers can be made to engage exactly alike. When the steering post is turned to the right in steering, the eccentric is thrown that way and the eccentric rod pulls the front of the power plant to that side which lessens or releases the contact of the right roller. This is of course the inner one and the proper one to release. The same action also tightens the outer contact and renders it able to take up the whole propulsion of the vehicle. The degree of release is proportional to the angle of the turn or practically so. The only parts required are the eccentric, its strap, rod and the two nuts. I cannot conceive a simpler device than this for the purpose.

And simplicity is not all, for it does the work better than the usual device. It drives the outer wheel. If one wheel slips on ice the engagement can be set tighter and it will then drive the inner wheel. In ordinary turning it drives the inner wheel some, although not powerfully. In straight going it drives both wheels alike. This makes it particularly adapted to solid tired rigs because their wheels bounce badly and with a balance gear of the usual type one or the other wheel is wasting the power of the engine by spinning in the air and then cutting the tires as they strike the ground. With the Buggyaut drive, the power of the engine is expended in propulsion so long as either wheel is on the ground. I feel sure designers and users have not paid enough attention to this part of the automobile's anatomy and am pleased that you are calling attention to it.

CHARLES E. DURYEA.

Reading, Pa.

The letter above from Mr. Duryea, as well as the two figures given, and the other devices are recommended to those interested in improvement of the automobile.



Photograph of Duryea Buggyaut Incorporating Differential

MAY EXPORTATION OF AMERICAN CARS DOUBLES

TO patriotic Americans there is perhaps no feature of the automobile industry which interests them more than the growing exportation of domestic-made automobiles. For many years the balance has been in the other direction, but a tendency to turn has been shown; and, in fact, during the month of May just past the exportations far exceeded the importations. Of course there are many more people going abroad with their own American machines, but nevertheless, there is a steadily growing foreign trade in the automobiles from the United States. The Department of Commerce and Labor has just issued its statistical summary of the month of May, and a comparison with that of the same month in 1908. By this it is shown that the number of domestic cars shipped to foreign countries was double that of a year ago, and two-and-a-half more than that of arrivals this year. Yet the importation continues to grow, for the comparison shows a trebling of cars, and a doubling of the value of parts, brought over. As an important side line, the figures on india rubber indicate that the amount imported was less, but the value was greater than previously.

During the month of May 519 automobiles of domestic manufacture were sent abroad, valued at $816,450, as against figures of 229 and $389,487 for 1908. But at the same time the necessity for supplying parts to American cars on foreign strands has decreased, for it is noted that this year the value of these shipped in May was $60,427, as against $69,570. It is likewise interesting to notice which countries have been included in the growing adoption of our nation's products in motor vehicle lines. The United Kingdom took a valued allotment of $281,180, doubling that of May a year ago; Italy received four times as many; British North America trebled its demand, taking cars worth $281,806 more than the mother country; the West Indies and Bermuda also received three times the former figures, and other parts of Europe, and British Australia both doubled their requirements. France and Germany both received more than in May, 1908, and Africa increased its valuation of imports from $127 to $3,422. There was also a decrease seen in some sections between the two months under consideration. Mexico dropped slightly, from $39,908 to $32,009; South America, from $21,534 to $14,913; the British East Indies, from $1,611 to $28 (automobile parts); other Asia and Oceania, from $10,598 to $666; and other countries, from $662 to $375. The decrease in the amount of parts necessary is, of course, a pleasing feature, showing improved wearing quality of American cars.

As to the importations of foreign-built cars to this country, the figures change from 72 in May, 1908, to 193 in this year, with the value from $170,185 to $301,971. A great many of the cars brought in were taxicabs. France has a strong lead, with 148 shipments, and the other countries are: Italy, 28; Germany, 8; United Kingdom, 5; all other countries, 4. The standing has not changed in the year. The sum of parts received almost doubled this spring, increasing to $72,616 from $42,515.

The situation in the rubber industry may be imagined from the fact that this year the importation was of 6,363,955 pounds as against 7,823,323 pounds, but the value changes in a different ratio, from $4,164,578 last year, to $4,450,356 this year, indicating an increase in the price of the raw materials.

British North America leads in the purchasing of American cars, with the United Kingdom second; France, third; other Europe, fourth; Mexico, Italy, Germany, the West Indies and Bermuda, and South America, following in the order named. This is considerable of an alteration in the score for May of last year, which read: United Kingdom, France, British North America, Mexico, Germany, South America, other Europe, other Asia and Oceania, and the West Indies and Bermuda.

NEW BOOKS FOR AUTOMOBILISTS

Internal Combustion Engines—As the title would indicate, this work deals primarily with the internal combustion *per se*, and not alone with its application to the automobile. However, all but five of the twenty-three chapters are pertinent to owners or operators of automobiles, and even those have an indirect interest. The five exceptions are Chapters III. on Diesel engines, VIII. on producers, XVII. on frames, XVIII. on foundations and XX. on governing. The first and last of these, it is true, have something of great interest as representing future possibilities than present everyday use.

Of the other chapters, the history of the gas engine is well written, and the two and four cycles are carefully explained in terms which the beginner could easily understand. One of the best chapters in the book deals with carburetters and fuel vaporization. With the exception of the extensive notice given to mixing valves, which are not in general use, this is excellent and brings out the principal points relative to fuel vaporization, always a difficult subject, in a very clear and intelligible manner. The chapters devoted to compression and the indicator card include all of the abstract mathematical formulæ given and are worthy of some study.

Most of the rest of the book is devoted to the detailed dimensions of the parts. In this, it appears as if the stationary engine is given the preference. Formulæ are given so that this portion of the book would be of great service to the designer. This part of the work, as would be necessary if it would be of use to designers, is right up to date, and valves in the head, copper water jackets, single cam for two valves, and other items of latter-day practice are described and commented upon.

The book is written by William M. Hogle, B. S., and published by the McGraw Publishing Company, 239 West Thirty-ninth street, New York City.

AUTOMOBILE CALENDAR OF EVENTS

Shows, Meetings, Etc.

Aug. 5-7..........Chicago, Midsummer Meeting Society of Automobile Engineers.

Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show.

Dec. 31-Jan. 7....New York City, Grand Central Palace, Decennial International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.

Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.

Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

July 12...........Detroit, Start of Sixth Annual A. A. A. Tour for Glidden Trophy.

July 12...........Portland, Ore., Road Contest, Portland Automobile Club.

July 31...........Richfield Springs, N. Y., Hill Climb, auspices of the "Earlington."

Aug. 5...........Chicago, Fourth Annual Algonquin Hill Climb, Chicago Motor Club.

Aug. 26-28.......Minneapolis, "Little Glidden Tour," Minnesota State Automobile Association.

Aug. 19-21.......Indianapolis Motor Speedway, First Race Meet.

Sept. 6-11........Lowell, Mass., Automobile Carnival, Lowell Automobile Club.

Sept. 15..........Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.

Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-mile Race, Fairmount Park, Quaker City M. C.

Dec. 29-30.......Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

THE SCOTTISH TRIAL

By Joseph A. Mackle

Climbing Amulree Hill near Loch Freuchie

GLASGOW, June 21—The searching nature of the annual trial of the Scottish Automobile Club has always been admitted, but there is no doubt that the event just completed ranks far ahead of its predecessors in this respect. Before mapping out the course of 1,000 miles, longer by 200 miles than the usual distance, the trials committee had scoured all the byways and mountain tracks of the northern country, and the net result proved to be something of a startler for most of the competitors. But, then, the modern car is so reliable under normal conditions that it requires an extremely severe test to render defects apparent, and only a gruelling such as is rarely encountered under normal conditions can afford a reliable indication to the buying public. Nineteen only of the sixty-five cars that started away on Monday last have returned with clean records—a proportion much smaller than usual—showing that the trial has succeeded in its object, while at the same time, the fact that no less than 58 cars finished in schedule time speaks well for the general qualities of both the cars and their drivers.

The total distance was divided up into six daily runs of approximately 170 miles each, and, as noted later, every part of Scotland—save the extreme south—was traversed, and every conceivable variety of road encountered.

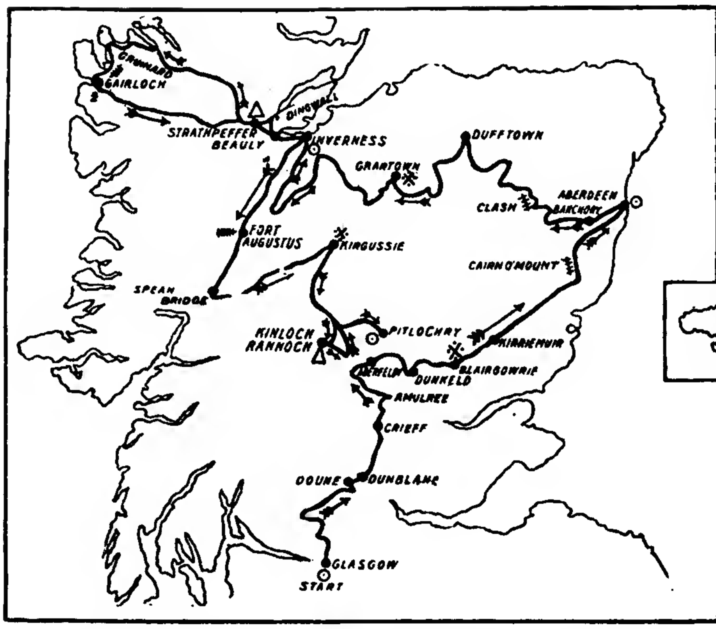
Sixty-five Starters Divided Over Eight Classes—The 65 cars were divided into eight classes on a price basis, but in Class H, for price above $3,250, the 50-horsepower Ariel was ranked by itself, which fact clearly demonstrates the decrease in popularity of the big car. By far the greater number of cars were of British origin, while the only representatives of America were the 10-horsepower and 20-30-horsepower Cadillacs, in classes B and D respectively. Both of these cars maintained their customary reputation for reliability, but while the latter made a perfect score, the former was delayed three minutes on the road for the fitting of a new commutator spring. This is the first stop that F. S. Bennett, the Cadillac representative, has had in any of the five annual trials in which he has driven.

After an early start at 7 A.M. on Monday, the cars were driven north to Aberdeen, but instead of the main road, a circuitous journey was taken to include the now famous Amulree and Cairn O' Mount Hills. The former of these has several pieces of reputed 1 in 4 (25 per cent) grade, and as these are found on bad hairpin corners, the drivers had a very exciting time. Nearly a dozen cars had to shed passengers or else required assistance, and these failures were by no means confined to the smaller classes, for overgearing seemed to be a general fault. The drop on the other side of Amulree was, if possible, worse, and the consensus of opinion now at the end of the trial is that this hill is the stiffest to be met with in the whole of Scotland. The Cairn O' Mount climb in the afternoon was easy by comparison, and after a dusty run the full number of cars reached Aberdeen inside the time limit.

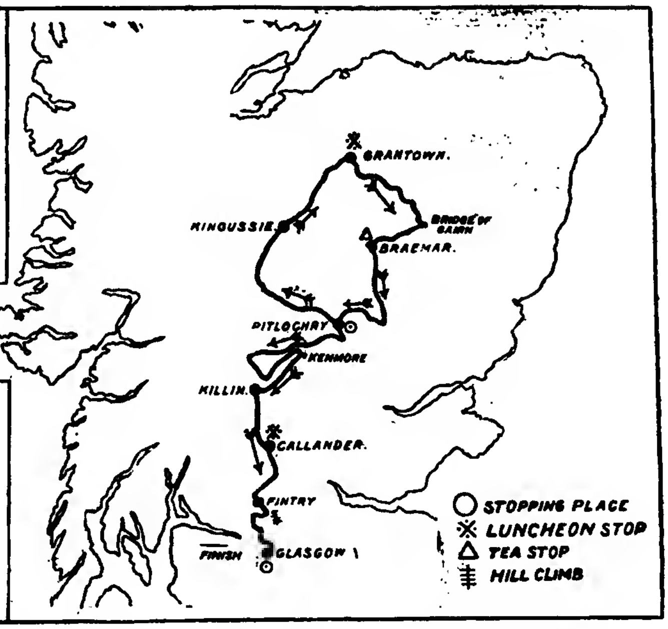
The next day's results were not so fortunate and the eliminations commenced early. Most beautiful country was traversed on the road for Inverness, which included in its course some severe climbing over Cairngorm. The ascent from the Bridge of Avon overheated the 8-horsepower Chenard Walcker so much that a cracked water jacket ensued, causing the withdrawal of this sturdy little car. Immediately afterward the 45-horsepower Austrian Daimler was withdrawn.

Austrian Daimler Out on Account of Overgearing—This car is a new production from the Neustadt works of the Mercedes Company and was expected to put up a very creditable performance, but its gearing was much too high for Scottish roads, so that on several hills outside assistance had to be called up. The smaller car of this make, rated at 30-horsepower, made a much better showing. Throughout this day overheating was prevalent to an unwonted degree and many cars hitherto blameless in this respect experienced engine and radiator troubles. The timed ascent was at Clash Hill, but on account of the comparative easiness of the grade, which nowhere exceeded 1 in 10 (10 per cent), only classes A, B, and C were raced up it. The Riley runabouts took the honors in the first two and the 10-12-horsepower Humber in Class C—a state of affairs maintained throughout the series of climbs.

In the afternoon, near the Fall of Foyers, famed for its aluminium works, the big Ariel struck a corner, but after a change of the Rudge-Whitworth detachable wire wheels, the car was



Plan of route for the first, second, third and fourth days



Plan of the route selected for the fifth and sixth days

Outline Maps Showing the Ground Covered in the Scottish Reliability Trials

able to proceed. The Gregoire and Rapid cars had lengthy stops on the road, and the 38-horsepower Knight-Minerva, which had quite come up to expectations on the hills, spoiled its record by an hour's clutch trouble.

Wednesday took the cars over new ground, right across to the western seaboard. Desolate marshes and lonely glens afforded a strong contrast to the country previously traversed, and the newness of the scene quite atoned for the execrable nature of some parts of the road. On one of the worst places the 40-horsepower Gladiator broke a front spring, quite an unusual occurrence—on this side, at any rate. On reaching the coast the cars dropped down to sea level in order to ascend the cliffs again by Gruinard Hill. After the formidable tasks of the first day Gruinard proved less trying than had been anticipated, and no failures were reported. Gairloch was the place of the luncheon stop, after which a straight run across the most beautiful part of the whole tour led back again to Inverness. Troubles were conspicuous by their absence, and, additional to the Gladiator, only the 20-horsepower Sunbeam experienced long delay. This, caused by a punctured carbureter float, was the first stop experienced by the driver, Eastmead, in the five annual trials. A like run of success was spoilt on the following day, when Bennett had a stop of but three minutes on his Cadillac.

Foreigners Win Thursday's Hill Climb—The cars headed southward again on Thursday, following the course of the Caledonian canal as far as Fort Augustus, where, alongside the ancient Benedictine monastery, a hill-climb was arranged for the bigger cars. On the previous days the British cars had been having all the awards in the climbs, but now the tables were completely changed and the Austrian Daimler and the Adler both swept the board in their classes. Many cars experienced trouble later in the day and less than half the cars finished at Pitlochry with a clean record from the commencement of the trial. Both the 20-horsepower Mass and the 30-horsepower Vinot were withdrawn, a succession of minor stoppages having robbed them of all chance of success.

From Pitlochry a circuit of 160 miles was made on Friday over the stiffest country that could be found. The Bridge of Avon and the other severe hills of Tuesday were taken in the reverse direction and the ascents and descents were universally reported to be much worse than previously. Fortunately the weather remained good—quite a record for the Scottish Trial, which has usually been run in a continuous downpour from start to finish. On this route the brakes of the cars were tested by the officials at a surprise control, and despite the fact that, by a wise dispensation, free time was daily allowed for brake adjustment, three cars were penalized for failing to come up to the required standard. No timed climb was held on this run and stoppages were less in evidence, so that 40 cars managed to make a non-stop for the day. The fates were less propitious on Saturday, and during the final portion of the run back to Glasgow the Argyll and the S. P. A. were put out of the running by a broken connecting rod and a stripped differential pinion, respectively, both cars by chance having had a perfectly clean record up to this point.

Of the 65 starters no less than 58 completed the trial, a highly satisfactory result when the unusual severity of the test is considered. Forty-three non-stops were recorded for the last day and for the total distance the following 19 cars had no penalties against them:

Class A—None.
Class B—12-horsepower Adler, 12-18-horsepower Riley.
Class C—10-12-horsepower Humber, 14-16-horsepower Miesse.
Class D—15-horsepower Mass, 20-30-horsepower Cadillac, 15-horsepower Straker Squire, 14-16-horsepower Argyll, 15-horsepower Star, 16-horsepower Singer.
Class E—20-horsepower Vauxhall, 16-horsepower Humber, 20-horsepower Lancia, 15-horsepower Rover, 12-horsepower Talbot.
Class F—18-horsepower De Dion, 14-20-horsepower Sunbeam.
Class G—30-horsepower Adler, 24-30-horsepower Albion.
Class H—None.

For the final awards the results of all the climbs are taken into account, as well as the fuel consumption, so that the placings will not be known for another week. The formula used was: Total Marks =

$$\text{Marks for reliability} + \frac{\text{Total Marks for Hill Climbing.}}{\text{No. of Hill Climbs.}} + \frac{\text{Lowest fuel consumption per ton mile in Class} \times 100}{\text{Fuel consumption per ton mile}}$$

Maximum marks for reliability were 850; for each climb, 50.

Kennels on Autos for Canine Travelers—An English automobile firm, according to *Popular Mechanics*, has built a car with a body which opens at the back, revealing a roomy kennel for carrying dogs. It is the idea that the cars run too fast for dogs to follow on foot, or to trot contentedly along between the rear wheels of a carriage, as when the horse was supreme. The general impression, however, is that the dogs will not be at all satisfied with being cooped up at the rear, for those seen in autos generally insist on having the seat of honor—next to the driver.

EDGE IMPRESSED WITH AMERICAN AUTO INDUSTRY

LONDON, June 29—Selwyn F. Edge, the well-known British autoist, has returned from his trip to the United States enthusiastic over the progress of the industry there. That he was evidently impressed by its development has been shown by the statements made by him in interviews, and his opinions have considerably surprised English manufacturers. It has not been generally accepted that the production of the American factories for 1909 of cars that are really serviceable would reach the sum of probably 80,000. Nor has it been thought that the increase predicted to perhaps 175,000 automobiles for 1910 was anything but publicity. Mr. Edge, however, has assured his fellow-makers that these reports are correct, for he has seen evidences of them. He says:

"Nearly everybody in America is going in for some sort of car and the fever has reached the remotest villages in the farming regions. Many farmers have learned that the automobile is not only a great machine for pleasure, but an even more important means of pushing modern business. Gasoline, sooner or later, in large measure will supersede the horse in hauling grain to market and drawing heavy plows. American manufacturers of cars are close students of the demands of public conditions in the country. They are also ingenious, inventive, and immensely enterprising. The finest cars made in America are equal to the finest made in the world, and the cheaper American cars are without equals in any other country. They give more value for their cost, weight, and size than any other article of manufacture on wheels. Unless the European manufacturers wake up to the importance of the cheap-car market, and produce more cheap cars; and better ones, the Americans are going to sweep Europe with these machines as they are now sweeping America.

"The Yankees have lots of bad roads, but they are finding out the best way to negotiate them in automobiles. Moreover, they build cars that go after bad roads and hills like a hungry boy after popcorn."

BRITISH PRESSITES "SENT FROM COVENTRY"

LONDON, June 22—Newspaper representatives of the British Empire, attending the Imperial Press Conference, were given an especial treat on June 15 as the guests of the Daimler Company of Coventry. A beautiful ride in thirty-three of the newest of English Daimlers through the Shakespeare country, an impromptu hill climb, and lunch at Warwick Castle featured a memorable day. The journalists assembled on a special train which reached Coventry at 11.30, and at the immense works of the automobile builders a reception was tendered them by the Mayor and officials, including C. Y. Knight. After inspecting the factory the party took possession of the automobiles and were conveyed to Warwick Castle, via Kenilworth and Leamington, where Lord and Lady Warwick entertained at luncheon.

The famous Sunrising Hill was an interesting part of the route and the Daimler Company had arranged a telephone system to insure safety. All machines went up with little difficulty and the journey continued to Cromwell's Tower, where a beautiful view of the Avon valley is obtained. Tea was served at the White Lion, in Banbury, and the run to Oxford made in the evening, the delegates spending the night in the university town. The Daimler Company not only furnished the cars but in many small ways cared for the comfort of the tourists.

Press Delegates Visit Warwick Castle

What the Clubs Are Doing These Days

MINNESOTA PLANS "LITTLE GLIDDEN TOUR"

MINNEAPOLIS, MINN., July 3—A "Little Glidden Tour" is now being arranged by the officers of the Minnesota State Automobile Association and will be held on August 26, 27 and 28. It is proposed to make the event a strictly amateur event run under the same rules as the Glidden tour. The St. Paul *Despatch* has given the principal trophy, a $500 silver cup, which is to be contested for annually, and Col. F. M. Joyce and H. S. Johnson have each given a $100 trophy, to go at once to the clubs whose cars win in the runabout and in the toy tonneau classes. Three routes are projected, one to Fargo, N. D., and return; another through Southern Minnesota, visiting 15 towns and cities where there are live automobile clubs, and the third route to Duluth and return. Each club in the State association, of which there are 25, will enter one and possibly more cars, and in all at least 40 cars are expected. H. S. Johnson, chairman of the tours and contests committee, will have associated with him on that committee one representative from each of the clubs.

SPRINGFIELD, MO., CLUB A REALITY

SPRINGFIELD, MO., July 5—For the past two years the Springfield Automobile Club has been an organization in name only, but a number of the automobile owners have set about to resuscitate it. The following officers have been elected: President, W. H. Horine; vice-president, Holland Keet; secretary, J. E. Atkinson; treasurer, Robert L. Pate. Two matters of immediate interest brought about this movement: first, to determine, if possible, upon the persons who have been stretching wire across the National boulevard, causing two accidents to autoists: and second, to organize a tour to Kansas City to meet the Glidden tourists. It is probable that a number of local cars will leave this city on July 26 to see the finish of the big contest.

HARTFORD HAS PARTIAL ORPHANS' DAY

HARTFORD, CONN., July 3—There seems to be something always interfering with the Automobile Club of Hartford's celebration of orphans' day. It had been planned to hold it during the national week, but rain prevented. The following week the children had some other function, and ever since then the club and the institutions have been unable to set mutually favorable dates. The club members have decided to let the orphan asylums name the day for the outing. About 50 of the children from the St. Patrick Orphan Asylum were given an afternoon diversion on Wednesday, when they were taken to Cromwell, where refreshments were served in a cool, shady grove.

BAY STATERS DECLINE UNION

BOSTON, July 3—The latest attempt to consolidate the Bay State Automobile Association and the Boston Motor Club, under the name of the Bay State Motor Club, has come to naught. The members of the Bay State Association at a special meeting this week refused to accept the terms agreed upon by the directors of the two organizations.

ROCHESTER AUTOISTS ASK POLICE POWER

ROCHESTER, N. Y., July 5—The Automobile Club of Rochester has decided to assist the local police authorities in stopping speeding, by watching its own members. It is planned to have ten members with police power to report those who drive too fast. The latter will be asked by the club to desist or be reported to the police.

GOOD ROADS CONCERT IS A NEW ONE

LANCASTER, PA., July 5—Agitation in favor of good roads has assumed many forms, but the Lancaster Automobile Club has discovered the newest one, that of giving concerts in behalf of better highways. In different localities out through the country, semi-monthly entertainments are held with the best musical talent procurable, and a nominal admission fee charged. The event is widely advertised in advance as "for the benefit of the good roads movement in Lancaster County," and a split-log drag is kept in front of the concert hall for several days previous to the musicale. At the most recent of these affairs, held in the Borough of Mount Joy, club members attended from all over the county, and the farmer element was proportionately strong. About $100 was cleared for future expenditure in conducting the good roads campaign. As a result of the work already done the county clay roads are in splendid condition, in some places being much better than the old pikes.

CHARLESTON, S. C., AUTOISTS ORGANIZE

CHARLESTON, S. C., July 5—For many months the automobilists of this city have talked of and much desired an automobile club, to foster their interests along lines of legislation, good roads, and sports. On Wednesday evening a number of them met and formed what will be known and incorporated as the Charleston Automobile Club. The following officers were elected: President, Wilson G. Harvey; vice-president, E. W. Durant, Jr.; secretary, Lane Mullally, M.D.; treasurer, F. G. Davies; solicitor, J. N. Nathans, Jr. These officers, with C. Norwood Hastie, Julian Mitchell, and E. W. Hughes, will form the charter members and take the first steps toward increasing the membership, determining the amount of dues, and considering any other immediate questions. At an early meeting it is planned to elect a board of governors and appoint a number of committees. Inasmuch as there are over 175 automobilists in the city a representative number is expected in the new organization.

NEW CLUB FORMED IN DETROIT

DETROIT, July 5—The Detroit Motor Club is the latest addition to local automobile organizations, having been launched last Thursday evening. Over 100 members have already been secured and it is predicted that inside of two months the list will have been increased to a thousand. Officers elected for the ensuing year are: President, Joseph F. Stringham; vice-president, J. S. Haggerty; secretary, John Gillespie; treasurer, George S. Lawson. The board of directors consists of these officers and Herbert J. Flint, Frank Briscoe, W. F. V. Neumann, Robert K. Davis, Charles Grant, Robert Kuhn, and T. W. Henderson.

All owners of motor cars are eligible to membership and it is planned to give Detroit an automobile club on a more practical and comprehensive basis than it has ever had.

SPRINGFIELD HAS SECRET TIME RUN

SPRINGFIELD, MASS., July 2—For a genuine good time, and a contest feature that gave every man an equal chance, whether his car had a single cylinder or six, the reliability run of the Automobile Club of Springfield went far ahead of anything the organization has ever fostered. Carrying about 100 people, 26 automobiles participated in the event on Monday, but the findings of the committee were not announced until last evening. In reality the competition was a side issue, as compared with the good fun expected and found by those who entered. A route of 37 miles in length had been selected, over which the cars were to be driven at an average speed of 15 miles an hour, and there were secret checking stations to see who came nearest to this. Principally, however, there was a clambake at the finish, at the Auto Inn, North Wilbraham.

When the scores of the cars had been carefully examined it was found that Henry Cave had taken his Stevens-Duryea through on the best schedule, his total time off at the various stations being 3 minutes and 38 seconds, thereby winning the Fisk Rubber Company's silver cup. This must be won three times in succession by the same person in order to secure it as a permanent possession. George L. Aikey, in an American roadster, took the second honors, and was awarded the Stevens rifle donated by the Stevens-Duryea Automobile Company. James Duckworth, in a Knox, won third prize, the Knox Automobile Company's gold medal; and a basket of lemons and carnations was given to J. C. Burke as a consolation. Mr. Burke drove his Cadillac with little regard for the time, and was almost two hours off. Only bona fide club members in good standing were allowed to compete.

The start was made from the club headquarters in the Worthy Hotel at 9 o'clock in the morning, an hour after H. S Sterns, in the confetti car, had left to mark the crossroads and turns. The first car away was that of Harry Fisk, and the others followed at intervals of three minutes. When 19 had been sent off there was an intermission of half-an-hour. Then the remaining contestants proceeded, also with the three-minute separation, Dr. F. C. Collins bringing up the rear with a large American flag, in his Cadillac, to mark the end of the caravan. The police closed Worthington street during the preliminaries to prevent confusion. The machines swung away from the checker toward Brightwood, out Chicopee street, over the State road, through Aldenville, Williamansett, Holyoke, South Hadley Falls, Granby, Belchertown, Ludlow reservoir, Boston road, Nine-Mile Pond, and to the Auto Inn, at North Wilbraham. Stop watches, odometers, speedometers, and dash clocks received the most critical inspections of their existence, even more so than when police traps abound. This was no more than reasonable, since in the one case an error meant little while in the other case it was sure to disqualify the owner from the contest. Some of the results obtained in this way were truly remarkable.

The first checking station was between Granby and Belchertown, with Ernest J. Dexter in charge: and the second was at the 30½-mile mark, near the Ludlow reservoir, presided over by Frank W. S. King. The contestants had all checked in between 11 and 12 o'clock at the inn, and while the clambake received its finishing touches, picked teams amused the crowd by playing "at" baseball. By the time the non-contestants had arrived the entry list for the clambake had increased to about 140. The committee in charge of the entire outing was comprised of Dr. C. S. Murless, T. B. Gilbert and H. S. Stearns.

AUTOING GROWS IN WESTERN CANADA

WINNIPEG, CANADA, June 26—The present year has seen a wonderful growth in automobiling throughout Western Canada, and dealers have found it impossible to fill orders which have been placed for cars. The vigorous selling campaign which was carried on throughout the prairie provinces during the Winter and early Spring months resulted in numbers of cars being sold in all the small towns, some of which, with a population of less than 500, now having seven or eight automobiles to mark the general prosperity which resulted from the harvest of 1908.

In Winnipeg, the great distributing centre of Western Canada, the phenomenal increase of business has made it necessary for some of the dealers to increase their garage facilities, the McLaughlin Carriage Company, Ltd., of Oshawa, Ontario, having erected a fine new building in Winnipeg as headquarters for its western business. The construction throughout is of reinforced concrete, making the building practically fireproof. Accommodation is provided for upwards of 100 cars, and the repair shop is equipped with the most modern plant. A new concern under the name of the Canadian Western Electric Automobile Company, Ltd., has been incorporated with a capital of $30,000, and will manufacture storage batteries, dry cells, and a small electric vehicle, the design of which has not yet been settled.

The good-roads movement has received considerable support, and a joint committee of representatives from the city of Winnipeg and neighboring municipalities has been appointed to arrange a combined method of carrying out the improvements. The provincial government has signified its intention to assist the movement, and it is confidently expected that when the 1912 world's fair takes place in the prairie capital, there will be hundreds of miles of good roads running into the city.

The Automobile Club has arranged for a pleasure tour commencing on or about August 7, to Regina, and W. C. Power and H. A. Aylwin have been appointed official pathfinders, and will leave Winnipeg early in July to map out the route. Immediately following the tour, the annual reliability run will be held over the same route as in 1908, for the Oldsmobile trophy. The speed events for the Dunlop trophy will be held on the Kirkfield track, but no definite date has yet been fixed for the event.

Commercial vehicles are gradually coming into use, the Canadian Pacific Railway Company having three big Argyll trucks; the Canadian Northern, three Packards; the Central Dray Company, a "Rapid" light van. The Maple Leaf Renovating Company has a small delivery machine which is making a good showing for quick delivery of small parcels, and attracting the attention of the retail merchants toward modern means of transportation. If this year's harvest is satisfactory, the sale of cars next year will far outrival even the present season's record.

In this way a few are converted each year to the commercial cars, and they, in turn, convert their neighbors, so that the number of vehicles in use grows every year.

Reliability Run of the Automobile Club of Springfield, Mass., at the Auto Inn, at North Wilbraham

AN EPOCHAL TYPE OF ENGINE

History has it that all pioneers were poorly treated, and in this one American trail-blazer named Brayton was no exception. Brayton was, however, always given credit for the fundamental work which he did in connection with the development of a new type of internal combustion engine. Now that much interest is being manifested in the efficiency of motors as well as in the larger question of fuels, the time for a revival of the type fathered by the Philadelphia inventor is as particularly well chosen as Brayton's own attempt was badly timed.

This form of engine, described somewhat in detail in this issue, as revived in an improved form, is likely to receive very good support from all those who have sought a more efficient, more flexible engine adapted to burn any kind of fuel and do so economically. In the constant pressure type of engine now given some notice, all these much-desired results are attained and, what is seldom the case, without a consequent sacrifice of something else. This holds unless the mere matter of number of parts be considered a positive detriment or come in the "sacrifice" class, which, to say the least, would be far-fetched.

When it is considered that the constant pressure engine, as constructed by Stilz, is in addition self-starting, any possible objection which might be raised on the score of number of parts, loses force, for is not the ordinary engine, with the addition of a self-starting device (where that is possible) complicated and composed of many parts?

So it is that Stilz, taking up Brayton's thirty-five-year-old engine, but with improvements of his own which make it a commercially feasible proposition, is due for all of the credit that usually goes to a pioneer with a meritorious or apparently worthy invention.

* * *

REVIVAL IN BLOCK TYPE OF MOTOR

Not infrequently it happens, in the introduction of something new and decidedly different, that the scorn and ignominy heaped upon the introducers is out of all proportion to the value of the device fostered. And not infrequently it also turns out, in conjunction with a change of this sort, that the merit recognized tardily by the original critics is ultimately adopted by them.

So it was with the style of engine in which the cylinders, two, three, four, or six in number, were cast in a unit. Formerly these were spoken of using the French phrase *en bloc*, but now it has been Americanized and we say the "block type." This type of engine was a prolific source of discussion from a year and a half to a year ago, following its adoption by the foremost French constructors. After much discussion and an endless amount of criticism, the subject was dropped under a blight, perhaps.

Now, one year later, it is a noticeable fact that all of the new-model, small-sized cars are so equipped. Not only this, but in the interim, many makers have quietly adopted the same form of construction, so that to-day the American makers, taken as a whole, present as many sterling examples of the block construction as do the originators of it, the French.

From the point of view of the man who buys a medium priced machine, the block construction representing the extreme of simplicity, means less sources of trouble and also lower first cost. By reducing the cost, this construction has placed the automobile within the reach of an increased number of people.

Considering the simplifications which this form allows and, in fact, fosters, it will be a great surprise if in the long run it does not displace the small-sized twin-cylinder casting, as well as the individual-cylinder type, so that ultimately for all motors of four-inch bore or less, the block casting will displace all others.

* * *

AND NOW THE YEAR'S BIG TOUR

Never before have the participants in the big annual tour of the A. A. A. been asked to travel such a distance, and this under rules more exacting than in any previous year. But it is with no doubt as to the outcome that the prediction is freely made that the 2,600-mile journey will redound to the reliability credit of the American automobile industry as a whole.

The territory traversed, with slight exception, will experience its first "Glidden tour," which means that housands will gaze in wonder at the dust-covered cavalcade, and be impressed with the ability of the motor-driven vehicle, despite the inevitable dishevelment of the participants, for in the Middle West clothes count for less than wholesome manners and man's belief in mankind.

The Gliddenites of 1909 will have pleasant recollections to revive along with the memories of hardships and dusty roads, for the welcomes will be innumerable and genuine.

SEPT. 6 AND 8 FOR LOWELL'S NATIONAL STOCK RACES

LOWELL, July 6—The dates and character of the national stock car races to be run on the Merrimac Valley course were practically decided last week when Chairman Hower of the A.A.A. contest board, President L. R. Speare, Harry Knights, Boston representative of the board, and Fred J. Wagner came here for a conference with President Heinze of the Lowell Automobile Club and others interested in the automobile carnival, and to inspect the course.

Monday, September 6—Labor Day—there will be a sweepstakes race with four classes at distances varying from 110 to 250 miles.

Wednesday, September 8, the race for large cars will be held at a distance of from 300 to 400 miles.

These are the dates now agreed upon and probably there will be no change. The exact distances will be settled a little later. A $5,000 trophy will be offered for the Wednesday race and suitable trophies for the different classes in the sweepstakes event.

Chairman Hower was well pleased with the course and believes that the ten-mile circuit will provide some of the sportiest racing ever seen in America. Fred Wagner is confident that cars can be started easily at 30-second intervals, which will permit a field of 20 cars in each event. That both races will have plenty of entries the officials are certain, and they will include the fastest of American and foreign cars.

An elaborate special invitation to President Taft to attend the races has been prepared and will shortly be forwarded to him. It has been signed by the governor, lieutenant governor, president of the senate, speaker of the house, Congressman Ames of the Lowell district, Mayor Brown of Lowell, President Speare of the American Automobile Association, and President Heinze of the Lowell Automobile Club. It is thought that at the time of the races President Taft will be at his summer home in Beverly, and it is hoped that he may decide to accept the invitation to attend the national stock car events.

QUAKERTOWN MAY INVITE FOREIGNERS TO COMPETE

PHILADELPHIA, July 2—The lack of entries which spoiled the Quaker City Motor Club's State-highway run to Pittsburg and return, and which compelled the abandonment of its proposed 24-hour race and the substitution therefor of a one-day meet, has made that organization's contest committee wary to a degree. Both of those affairs, before their details had been made public, had been assured sufficient entries to make them successful. When the time came for a showdown two-thirds of the promised cars failed, for one reason or another, to materialize. Chairman Ross will take no chances on a similar throw-down for the club's second annual 200-mile Fairmount Park stock chassis race, scheduled for October 7 next.

The contest committee originally decided—and, indeed, prefers—that the race should be limited to American built cars; but having in hand several bona fide foreign entries, Mr. Ross prefers not to refuse them until every home manufacturer shall have had a chance to come in. There is only room for a score of cars, and if, within a reasonable time, American builders have not sent in a sufficient number of entries to complete the list, the door will be thrown open to the foreigners.

The committee has sent out notices to all American manufacturers of fast cars to get in early.

ACTIVELY PREPARING FOR ALGONQUIN'S CLIMB

CHICAGO, July 3—Sixteen events, five more than last year, are upon the program for the Chicago Motor Club's annual hill climb at Algonquin. This will be held August 5 and really consists of 32 events, for the affair is held on two hills—one in the morning, a standing start effort, and the other in the afternoon, when the cars tackle another grade with a flying start. Both hills count, however, in deciding the winners. Six of the classes will be decided under the Chicago Motor Club formula, in which the cylinder capacity is multiplied by the time, and that result divided by the weight of the car with driver. The classification is to be by piston area, the program adopted at yesterday's meeting of the contest board being as follows, subject of course to the action of the A.A.A. contest board, which has been asked for a sanction:

DIVISION 1—HANDICAP

Class A—One or two-cylinder cars with piston area under 50 square inches.

Class B—Four or six-cylinder cars with piston area under 50 square inches.

Class C—Four or six-cylinder cars with piston area over 50 and under 65 squaer inches.

Class D—Four or six-cylinder cars with piston area over 65 and under 90 square inches.

Class E—Four or six-cylinder cars with piston area over 90 square inches.

DIVISION 2

Class F—Free-for-all, open to motor buggies, wheels 36 inches or over, solid tires.

Class G—Free-for-all, open to electrics.

Class H—Western amateur handicap championship, for four or six-cylinder cars, winner to be decided by the club formula.

Class I—Amateur free-for-all, touring cars or roadsters of any power.

DIVISION 3

Class J—Free-for-all, any type of stock car with piston area under 65 square inches.

Class K—Free-for-all, touring cars, five or seven-passenger, with piston area under 65 square inches.

Class L—Free-for-all, any type of stock car with piston area over 65 and under 90 square inches.

Class M—Free-for-all, touring cars, five or seven-passenger, with piston area over 65 and under 90 square inches.

Class N—Free-for-all, any type of stock car with piston area 90 square inches or over.

Class O—Free-for-all, touring cars, five or seven-passenger, with piston area 90 square inches or over.

No change has been made in the entry fee, it remaining at $30 per car, with half of this sum refunded in case of a start. There must be at least three entries to a class to make a contest. The entries will close at midnight, July 30, with Charles P. Root, 1806 Michigan avenue.

TOUR THROUGH NEW YORK'S LAKE REGION

ROCHESTER, N. Y., July 6—The touring committee of the Automobile Club of Rochester has made definite arrangements for the first annual tour. The committee is composed of W. W. Dake, chairman, A. J. Cunningham, R. A. Hagen, and President H. G. Strong and Secretary Bert Van Tuyle, ex-officio. The tour will start from the Hotel Seneca July 22, at 9 A.M. The route passes through some fine sections of the State, and nearly all of New York's inland lakes are touched in the trip. Secretary Van Tuyle will start July 8 on the pathfinding trip, and will be accompanied on the journey by Karl W. Hibbard.

1910 WINTON MARKED BY FOUR-SPEED TRANSMISSION

As Mr. Winton himself has aptly put it, the Winton changes for 1910 are only incidental, not radical, barring the four-speed transmission and enlarged clutch. It has been found in the experience of the past and previous years that the engine was more powerful and had more speed than the high speed of the old transmission would allow the use of. So a new top gear has been added to the transmission to allow the owner, if he so desires, to turn the engine loose with the assurance that every possible turn of the crankshaft will be utilized in the speed of the car. Coupled with this change, there was a necessity for or advisability of a larger clutch than heretofore, which would handle the higher power and speed. So the diameter of the multiple disc clutch was enlarged 50 per cent. without changing the number of discs. A minor change was in the number of springs, the newer use of four allowing very slight foot pressure to engage or disengage the clutch.

While the motor remains exactly the same, superior fuel supply is attained by a newly perfected carbureter, located in practically the same place. This allows the full use of the flexibility of the six more than has hitherto been possible. The working parts are more closely enclosed, yet this is done without any sacrifice of accessibility.

Lubrication is unchanged, the force feed system with a continuous sight feed on the dash being retained. Similarly the successful self-starting device is retained. Now that much accent is being laid upon the starting problem, this is of particular importance. Pressure from the front cylinder is stored in a tank, whence a rotary distributing valve furnishes it to the proper cylinders in turn. The motor is started by pressing a foot button on the dash, the air pressure doing the rest. This whole system may be used for tire inflation by a simple attachment, thus doing away with the back-breaking work.

Greater Comfort Assured by Larger Springs—An item that never fails to interest is that of comfort. An increase in this is obtained by increasing the length of the springs, the style being the same as before. In addition to long, wide springs, four shock absorbers and four rubber bumpers are fitted.

One noticeable change, which may or may not be in the nature of an experiment, is the change in the material of the front axle. This has always been made of manganese bronze, but this coming year is to be of large section pressed steel. With the change in front axle, probably strengthening it, comes an increase in the wheel base. This has been increased to 124 inches, four more than previously.

To this chassis of greater length is fitted not a longer but a shorter body. In this way the maximum amount of comfort is obtained, as the various dimensions may be made as long or as great as possible. The regular body is the four or five passenger type, with bucket seats in front and a short tonneau in the rear. A seven-passenger body is made as an extra. The new tonneau doors are unusually wide. Running boards have been widened and are covered with pressed aluminum. All bodies are of wood, built especially to Winton designs.

In moving the main gasoline tank to the rear, a move for greater safety and increased convenience has been made. The three-gallon reserve feature which has become so popular will be retained. The main tank has a capacity of 22 gallons.

Other and minor features which have been subjected to change are: radiator with longer tubes, longer filler and hard rubber cap; hard rubber steering wheel rim, movement of operating levers nearer the seat as an option, longer spark and throttle levers, increased pedal leverage, with the option of long or short pedals; larger exhaust pipe and Eisemann dual ignition. With all these changes the price remains the same—$3,000.

WINTON BRANCH MANAGERS IN CONVENTION

Cleveland, July 3—Winton branch managers and road men enjoyed a busy convention here this week. There was something doing every minute from breakfast to good-night. Baseball, field sports, a yacht ride, a theatre party, and a trip to Luna Park were only part of the doings, which included every variety of luncheon and dinner except the formal kind. The participants were: Vice-President Henderson, Secretary Brown, Sales Manager Churchill, Advertising Manager Mears, Parts Manager Smith, Engineer Anderson, Traffic Manager Baughman, Superintendent Weidig, Purchasing Agent Ranney, and the following branch managers and road men: Messrs. Hinchcliffe, of Boston; Brown, of New York; Calvert, of New Jersey; Maltby, of Philadelphia; Stockbridge, of Pennsylvania; Duck, of Baltimore; Kiser, of Pittsburg; Brockway, Sealand and Walley, of Cleveland; Henderson and McCrea, of Detroit; Davis and Roe, of Chicago; Johnson, of Minneapolis; Lewis, of Kansas City; Miller, of Seattle, and Owesney and Arbuckle, of San Francisco.

STEVENS-DURYEA GIFT FOR QUEBEC PREMIER

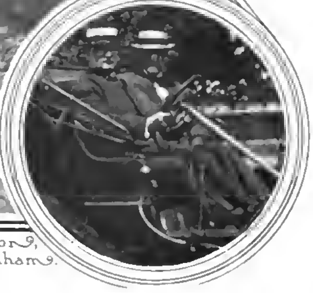
Montreal, July 5—Sir Lomer Gouin, premier of the Province of Quebec, has been presented with a six-cylinder Stevens-Duryea touring car by a number of his friends, as a mark of their esteem. The ceremony partook of the nature of a surprise at the St. Denis Club, while the big automobile stood nearby, and later in a trial showed the premier that it was well able to carry him up the hills of the city. Alderman Lavaller on behalf of his colleagues madé the presentation address. The car was sold by Managing-director L. D. Robertson of the Comet Motor Company, local distributor of the Stevens-Duryea.

PREPARATIONS FOR THE GARDEN SHOW

New York, July 5—While most automobilists who attend the annual shows in this city have not given the 1910 ones more than a passing thought, there are two bodies of men which are preparing for the great exhibitions already. For the tenth national show at Madison Square Garden, that of the Licensed Association of Automobile Manufacturers, active work is now going on. Contracts are being let, plans are practically all completed, and even the manufacturers are beginning to arrange for the machines which will compose their exhibits. The activity of the show committee, made up of Col. George Pope, of the Pope Company, chairman; Charles Clifton, of the Pierce-Arrow Motor Company, and E. P. Chalfant, of the Packard Company, has been of several months' duration.

Scores of carloads of lumber, special sheet and structural steel, burlaps, bunting, and other materials have already been ordered, and some are being manufactured. These will be used in constructing the balconies, which will be larger than usual, and for covering the walls and floors. The committee has succeeded in developing additional floor space this year, much to the wonderment of those interested, by increasing the width of the balconies. The elevated platform, which has been a feature for some years at the Seldenite exhibition, will be supported by a single series of posts, enhancing the artistic value as well as giving the necessary room, and will extend around the whole auditorium. The various corners and small rooms of the great building will be utilized as formerly, for accessory, motorcycle and commercial vehicle makers.

From the present indications the manufacturers will all have their new models ready well in advance. Some are even now preparing the cars which will be exhibited, and some wonderfully beautiful body designs are well under way.



President J L Hudson, Chief-Engineer Dunham.

SURPRISING as have been the car announcements of the past few weeks, none has excited the comment as has the announcement of the new car to emanate from Detroit, the Hudson "Twenty," by name. This will present in a concrete form all of the ideas in small car construction gained in the past season, and from a manufacturing standpoint will embody the results of twelve years of automobile construction knowledge. Starting with a staff of old experienced automobile men, concentrating its attention on a single model, and going in for a very large production, many economies are thus brought about, with the result which has aroused the automobile world, the price being but $900. This, with a Bosch magneto, top, gas tank, and extra rumble seat, being increased to $1,050.

Of the men behind this new car, most are well known in the industry, with the possible exception of the president, J. L. Hudson, one of Detroit's leading merchants. Of the others, Hugh Chalmers is president of the Chalmers-Detroit Motor Company. So, too, R. D. Chapin and H. E. Coffin are connected with the Chalmers company, while R. B. Jackson, general manager, and G. W. Dunham, chief engineer, both served many years with the Oldsmobile manufacturers.

Personnel Reflected in the Product—With such a motorwise bunch "on the job," it is not strange to find the product so meritorious. From the front to the rear of the chassis, every part has been carefully considered both for its individual ability and serviceability, and for its interrelation with every other part. Starting with the standard body, which is furnished for the single chassis to be manufactured, this is of the roadster type, with full front seat and single rumble in the rear. It is well made of selected poplar on sills of the best ash, the seat backs being poplar also. The large and roomy seats are upholstered in apple green, while the main color is a deep maroon. To set this off best, a fine stripe of old ivory is used, and black mouldings. With the maroon, black upholstering may be had, while with the green trimming, battleship gray will be furnished, if preferred by the prospective purchaser.

Taking up the real, beating, pulsating heart of the car first, the engine, this is of the four-cylinder variety, with cylinders cast in a block. In this, it follows the most modern and approved practice in small motors. The motor is of the T head type, with valves all on the right side, as used by the famous French constructor, Renault, until it is now called the Renault type. The cylinders, with 3¾-inch bore, are of the best grade of gray iron, with water space between the cylinders and of a very generous size around the exterior and at the ends.

Preference Given to Long Stroke—In the length of the stroke, 4½ inches, is shown another very modern tendency, the preference for the long stroke, slow speed engine. This gives for this car a ratio of bore to stroke of 1.2, which should make for strong pulling power at comparatively low speeds. Although the A. L. A. M. rating formula would allow of calling this sized engine a 22.5 horsepower unit, the makers have preferred to give it a lower more conservative rating and so call it a twenty.

The aluminum crank-case is in two parts, the upper carrying the two large plain crankshaft bearings, and being attached to the frame by means of four large section arms. The shaft is of large diameter, made from a high grade material, having a tensile strength of 100,000 pounds, and is ground to size. Not only the crankshaft, but the camshaft, cams, pistons, piston pins, valves, and many other parts are subjected to the grinding process to insure accuracy.

Engine lubrication is of the forced circulation splash type. An oil well of three quarts capacity is cast integral with the lower half of the crank-case, with a simple plunger pump, operating by an eccentric on the camshaft, raising oil from the well and forcing it directly to the parts.

By utilizing a carbureter of the Venturi tube variety, with ball auxiliary valves, the up-to-dateness which pervades the whole car is maintained. Ignition is by means of battery and timer, the latter, of the La Coste type, being independently supported at the rear end of the camshaft. From the engine the drive is through a large diameter cone clutch, faced with leather. Under this facing a series of flat springs make for easy and gradual engagement. The clutch thrust is well taken care of by a large ball thrust bearing.

First Small Car with Three-Speed Selective Transmission—Being accustomed to think of small cars as fitted with a planetary transmission, it comes as a surprise to learn that this car is equipped with a three-speed and reverse-gear box, operating on the selective principle. Like the engine, this is mounted in a two-piece aluminum gear-case, supported upon four large arms. The transmission bearings are also plain, and are provided with oil retainer chambers on the ends.

Both engine and transmission are secured to a sub-frame of the dropped type, which is made a part of the main frame. The latter is of pressed steel, the material being best open-hearth stock, with a 3½ by 1½-inch section.

The frame has what is called a drop at the rear of 2½ inches, this allowing the car to be hung low and at the same time have adequate clearance. With this drop frame is used three-quarter elliptic springs, 1¾ inches wide by 44 inches in length. With these, the front springs of 36-inch length are fitting companions.

An I-beam section front axle and a semi-floating rear axle complete the chassis, both being mounted on roller bearings.

Double Acting Brakes on Rear Wheels—Braking, always important, whether the car be large or small, is here well cared for by two large double-acting brakes located on the rear axles and acting on the interior and exterior of large diameter drums bolted to the rear wheels. The external brakes are firmly supported on brackets, which prevent rattle. Both brakes work equally well in either direction, and both are lined with a heat-proof asbestos fabric, which is readily removable.

Steering is by means of a gear of the worm and gear type, mounted upon exceptionally large bearings. The steering post is laid over at an exceptional angle affording a very racy appearance and placing the sixteen-inch steering wheel in a very comfortable position for the driver. The control aside from this is standard in that it follows the regular practice of standard cars.

Barney Oldfield in His New National Racer, "Old Glory"

PLAINFIELD HAS FIRST HILL CLIMB

PLAINFIELD, N. J., July 6—Charter Day celebration was featured to-day by a hill climbing contest on Johnston's drive, over a distance of seven-tenths of a mile, with nine difficult turns, and an average grade of 15 per cent. There were six events on the list and there were sufficient entries, and good ones, to give a successful affair. One mishap occurred to a National car which was driven by George Weldon, accompanied by William Bolen. They were just making the last hairpin turn within a few yards of the finish, in the free-for-all, when a wheel struck a wooden culvert, the car turned turtle and went over an embankment. Both men were thrown clear, but Bolen's shoulder was fractured.

J. R. Rutherford in a Stearns and George Rankin in a Chalmers-Detroit have equal claims upon the fastest time of the day, 1:28, made in two separate classes. A four-cylinder Maxwell, driven by William Sichinger, came close to this by winning a class event in 1:28½. The event was in charge of F. J. Titus. The summaries:

Pos.	Car	H.P.	Driver	Time
	CARS SELLING FROM $2,001 TO $3,000			
1	Chalmers-Detroit	40	George Rankin	1:29 2-5
2	Palmer-Singer	60	F. C. Lescault	
3	National	35	George Weldon	
	CARS SELLING FROM $1,251 TO $2,000			
1	Marion	35	Charles Stutz	1:36 4-5
2	Herreshoff	24	George Robertson	
3	Buick	30	C. S. Dutcher	
	CARS SELLING FROM $851 TO $1,250			
1	Buick	18	Easter	1:44
2	Overland	30	George Reese	
	CARS SELLING FOR $850 OR LESS			
1	Maxwell	22	William Sichinger	1:28 1-2
2	Maxwell	22	Arthur See	
3	Hupmobile	16	K. D. Martin	
	FREE-FOR-ALL			
1	Stearns	30	J. H. Rutherford	1:28
2	Chalmers-Detroit	40	George Rankin	
3	Simplex	50	W. Heltmeyer	
	WINNERS' CLASS			
1	Chalmers-Detroit	40	George Rankin	1:28
2	Maxwell	22	William Sichinger	

CABLES CREDENTIALS TO CHAIRMAN EVANS

NEW YORK, July 3—Powell Evans, in representing the A.A.A. at the London convention of the League Internationale Association des Tourists, will also be the real official delegate of the United States. Because of a hurried departure the necessary credentials on behalf of the government were not obtainable, but this week these were cabled to Mr. Evans from Washington. Secretary Elliott of the national body and Secretary S. Boyer Davis of the Automobile Club of Philadelphia had a conference early in the week with Vice-President Sherman, Secretary of State Knox, and Attorney-General Wickersham relative to the official recognition, and the cable message was the result.

REGAL EN ROUTE FROM YORK TO 'FRISCO

NEW YORK, July 5—At exactly noon the sturdy little four-cylinder Regal started from Times Square on its long trip to the Pacific Coast. Fireworks were intermittently sputtering, though one of the usually busiest places in the "big town" was tenanted by only a few unfortunates who had failed to escape to some resort or other. It so happened that the weather was exceptionally inviting and ideal for the beginning of a long automobile tour.

"Snow Ball Bill" Smith was at the wheel, with George D. Wilcox alongside as the route scout, while comfortably seated in the tonneau were Marcus Allen of the Empire Tire Company, Trenton, N. J., and R. P. Byrne of the Regal Sales Company, Syracuse, N. Y. These two will be replaced by others later on.

This is the first trip of its kind in trying out a new four-cylinder model of the $1,250 class, and the route has been so arranged as to visit all the Regal agents from coast to coast. No record-breaking schedule has been prepared, but the trip will be comfortably covered in 30 days, this being the itinerary as at present laid out:

New York, N. Y.		July	5	North Platte	Night	July	18
Poughkeepsie, N. Y.		"	5	Sterling, Col.	"	"	19
Utica, N. Y.		"	6	Denver, Col.	"	"	20
Syracuse, N. Y.	Noon	"	7	Cheyenne, Wyo.	"	"	21
Rochester, N. Y.		"	7	Rawlins, Wyo.	"	"	22
Buffalo, N. Y.	Noon	"	8	Rock Springs, Wyo.	"	"	23
Erie, Pa.	Night	"	8	Evenston, Wyo.	"	"	24
Cleveland, Ohio	Noon	"	9	Ogden, Utah	"	"	25
Toledo, Ohio	Night	"	9	Kelton, Nev.		"	26
Detroit, Mich.		"	10	Montello, Nev.		"	27
Goshen, Ind.		"	11	Battle Mountain, Nev.		"	28
South Bend, Ind.	Noon	"	12	Mill City, Nev.		"	29
Chicago	Night	"	12	Hazen, Nev.		"	30
Clinton, Ia.	"	"	13	Reno, Nev.		"	31

Carroll, Ia.	"	"	15	Sacramento, Cal.		"	2
Omaha, Neb.	"	"	16	San Francisco, Cal.		"	3
Grand Island	"	"	17				

Columbus, Ohio.—F. E. Avery is having plans prepared for a two-story addition, 65 by 127 feet, to his garage on Franklin avenue, between Champion and Wilson avenues. The floors will be of concrete and the exterior of brick.

The Packard Motor Car Company's Powers That Be

One cylinder of the new 3,000-horsepower engine that will supply the motive power for the Packard factory, at Detroit, and President H. B. Joy, General Manager S. D. Waldon, Manufacturing Manager C. J. Moore, and Chief Engineer Russell Huff.

NEW COLUMBIA COMPANY NOW A REALITY

HARTFORD, CONN., July 3—With the conclusion this week of the necessary formalities attendant upon the organization of the Columbia Motor Car Company, a famous automobile concern passed out of existence. It was the Electric Vehicle Company of this city, which had manufactured Columbia cars for years, held the Selden patent rights, and had been in the hands of the receivers since December 10, 1907. The entire assets of the now extinct concern, except cash in the hands of the receivers, have been transferred to the new one, and the production of Columbia cars will proceed with increased vigor. The following are the officers chosen: President, Herbert Lloyd, president of the Electric Storage Battery Company of Philadelphia; vice-president, treasurer, and general manager, Henry W. Nuckols, of Hartford, one of the receivers. The directors are Herbert Lloyd, Walter G. Henderson of Philadelphia, Henry W. Nuckols, William Hooker Atwood of New Haven, and Kenneth B. Schley of New York.

The change was made this week and the policies proposed for the coming season announced. A six-cylinder car will be added to the present line of gasoline cars, and both the output of these and of electric machines will be materially increased. The 1910 models are now in the process of building and will soon be ready for delivery. The same method of distributing—through agents—will be followed. The capitalization of the Columbia Motor Car Company has been increased from $48,000 to $3,000,000, divided into 30,000 shares. The receivers, Mr. Nuckols and Halsey M. Barrett of Elizabeth, N. J., have not been discharged by the court, and are now engaged in paying the 20 per cent dividend of the old firm's creditors.

CHANGES IN HERRESHOFF MOTOR COMPANY

DETROIT, July 5—Certain changes are impending in the organization and control of the Herreshoff Motor Company of this city. While not as yet completed it is understood that the rearrangement is made with a view to a better co-ordination between the factory and the Harry S. Houpt Company, the sales organization. The stock of the factory has until the present been held mainly by Charles F. Herreshoff and Louis Mendelssohn, but large blocks of this have been purchased by other interests. Mr. Herreshoff will remain as vice-president and chief designer, but the other officers have not been chosen. The Harry S. Houpt Company of New York retains the entire selling control and it is expected by both parties that the new disposition will be of material benefit. The output of the plant has been increased, and, it is stated, it will work at its full capacity throughout the Summer to supply the demand.

TO APPREHEND JOY RIDERS

PHILADELPHIA, June 7—Determined to bring the "joy rider" to book with a round turn, a number of prominent Quaker City Motor Club members, in conjunction with a well-known local detective agency, have formed the Auto Reporting Company, Inc., with main offices at 838 Real Estate Trust Building. L. D. Berger is president of the new company; Charles J. Swain, vice-president; Frank J. Curran, secretary and treasurer; G. Douglas Bartlett, the club's law committee chairman, is counsel, and Charles D. Sell, a prominent local detective, is the general manager; these, with George M. Costello, Thomas J. Curley and Howard W. Frame, compose the board of directors. The car of each subscriber will carry the company's emblem.

R. D. CHAPIN ABOUT TO VISIT EUROPE

R. D. Chapin, treasurer and general manager of the Chalmers-Detroit Motor Co., will sail for Europe the middle of July to spend the Summer and return in September. He expects to visit England, France, Germany, and Italy.

"Of course, I know that now one does not have to go to Europe to see good automobile races," said Mr. Chapin. "This trip is not simply for the purpose of seeing the automobile races and studying progress in aeronautics, although I shall take in a number of the big events as long as I am on the ground. I will be particularly interested in watching the speed results the foreigners are able to get with their small cars. There is no question in my mind but what the light car races held in this country have resulted in developing unusual horsepower efficiency from small bore and stroke motors."

WALTON HAS NO INTENTION OF CHANGING

H. E. Walton, manager of the Midland Motor Company, Moline, Ill., sends word to THE AUTOMOBILE that he has no intention whatever of leaving his present position and taking one with the automobile department of the St. Louis Car Company. In the news which Alfred Reeves supplied after his round of the A.M.C.M.A. factories it was stated that Mr. Walton was the general manager of the St. Louis Company's automobile department. Mr. Walton wishes it positively stated that he is perfectly satisfied with present conditions.

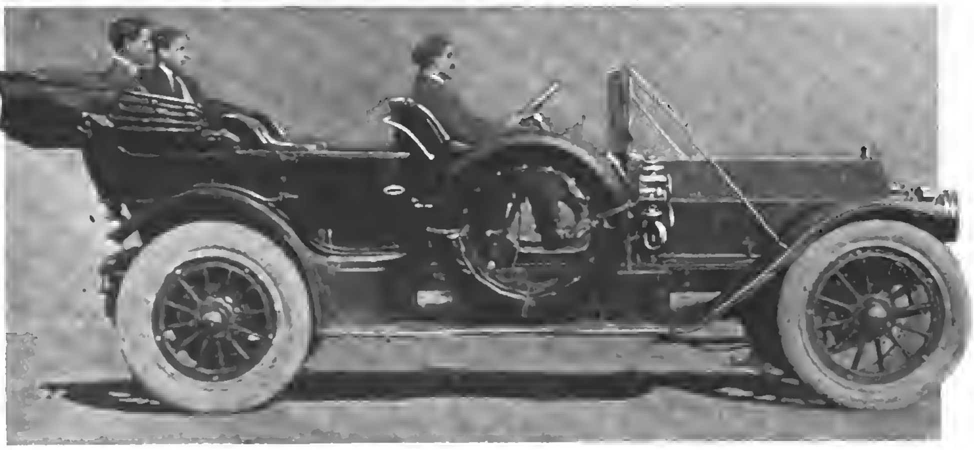
"PEERLESS" KITTREDGE SAILS FOR EUROPE

NEW YORK, July 2—L. H. Kittredge, president of the Peerless Motor Car Company, of Cleveland, sailed for Europe this morning on the Kaiserin Augusta Victoria. He took with him a 1910 Peerless touring car, and will use it extensively on the Continent. He expects to make the trip one of combined business and pleasure, and will be away about 60 days.

GENERAL MOTORS PROPOSES TO CADILLAC

DETROIT, July 6.—With a view to enlarging the scope of its activities, the General Motors Company has submitted a proposition to the Cadillac Motor Car Company. Officials of the Cadillac company admit that the proposition is under consideration, but negotiations have not been made public.

Battle Creek, Mich.—Plans for a new garage for Howard B. Sherman, to be built on Maple street, have been completed and the contract let. The structure will be of the bungalow style of architecture.



How the Largest Fisk Tires Appear on the Largest Stearns Car

The Fisk Rubber Company claims to have made the largest pneumatic tires ever built for an automobile. This photograph shows a 90-horsepower six-cylinder Stearns touring car fitted with Fisk tires and Fisk removable rims. The front tires are 40 by 5-inch ones, and the rear 40 by 6. These are made in a growing use of larger tires.

Old Way of Stretching the Fabric on the Core by Hand

TIRE MAKING BY MACHINERY

AKRON, O., July 3—For a number of years the Goodyear Tire and Rubber Company has been working to perfect a tire making machine that would turn out the right kind of Goodyear tires, and now has several machines in operation at the big plant in this city. In the old way of making tires by hand, they have been built up, first by a layer of fabric, then a layer of rubber, then another layer of fabric, and so on until the body of the tire was complete. As this fabric has always had to be stretched on by hand, by operatives skilled in tire making, the durability and longevity of a tire had been largely dependent on the skill and strength of the workman who made it.

To give the greatest mileage this fabric must be stretched to an absolutely even tension over each portion of the tire, and each alternate layer must be given the same tension as those that have previously been put on. It is self evident that this evenness of tension could not be faultlessly given when human hands were solely depended upon, and for instance, tires made in the morning, when a man is fresh, will be apt to be stretched more tightly and evenly than those made later in the day when the operator's muscles have become weary.

By the use of machinery for stretching the fabric a positively even tension is secured upon each strip of fabric used in a tire, and the Goodyear machines, shown in the illustrations, represent a marked step in advance in perfect tire making. The pictures are interesting to all users of pneumatic tires, and show both the hand and machinery methods.

How the Goodyear Tire Machine Stretches the Fabric

CARTERCAR WITH INTERESTING HISTORY

PONTIAC, MICH., July 3—Often interesting things are told, and wonderful feats are accomplished, with automobiles, but "What becomes of them after that?" is the question which is raised by R. A. Palmer of the Cartercar Company. This query was brought about by an incident which happened in connection with the Chicago agency of the company.

The twentieth car which was turned out by the Cartercar Company was sent to Hagmann & Hammerly who, like everyone else at that time, were skeptical about the friction drive which is a distinguishing feature of the Cartercar. They therefore drove the car over 800 miles through sticky Illinois mud, it being so thick on the car that the shape was all that was visible. But that was only a beginning. The machine was then put into demonstrating service. It was entered in the Chicago Automobile Club's reliability run and made a perfect score in 1906. After covering over 14,000 miles it was again entered in 1907 and took another perfect score. But that wasn't all.

After having covered a total of over 23,000 miles it was sold to H. B. Walker of Chicago. Mr. Walker now states that he drove the machine something like 4,000 miles more last season, and adds that although it has covered over 27,000 miles, it would require more than $1,000 to buy the car now.

Machine Rolling Fabric Down After It is Stretched

GROUT COMPANY IS REORGANIZED

ORANGE, MASS., July 6—A new company, chartered in this State with a capital of $150,000, known as the Grout Automobile Company, will take over the Grout Brothers Automobile Company, as a reorganized concern. The receivers of the old company will transfer the business, confident that it will be carried on even more successfully than during the recent months. The officers of the Grout Company are: President, Walter J. Gould; treasurer, E. S. Hall; secretary, George E. Dexter; and these also constitute the board of directors. The plant is well equipped for manufacturing automobiles and is capable of producing two a day. Judge Hall has had two years' experience with the factory as one of the receivers; Mr. Gould was selling agent of the former company; and Mr. Dexter is the secretary of the Chase Turbine Company, thus forming a trio well acquainted with successful manufacturing conditions.

Auto Carries Fresh Milk for Babies—The Columbus District Nursing Association is now operating a large automobile to carry fresh milk to the hundreds of babies in Ohio's capital city. The car is equipped similarly to a refrigerator freight car.

Koenig Brothers' Garage at Tarrytown, N. Y.—A Model of Its Type

WELL-KNOWN GARAGE ON HISTORIC GROUND

Tarrytown, N. Y., July 5—While the firm of Koenig Brothers, Rambler representatives at Tarrytown, has been doing business at the Old Post Road Garage for several years, it held quite a celebration recently to inaugurate its new and up-to-date garage. This is located in a historic country, alongside of what was, and still is called the Old Post Road, its name dating back several hundred years, to the times when the mail was carried by four-horse mail and passenger 'buses, called post-chaises. From the use of this road exclusively by the post 'buses came the name Post Road, which has been retained through all these years.

The garage is now housed in a new two-story, fire-proof building of reinforced concrete. The ground floor, 50 x 85, will be devoted exclusively to storage, sales and locker rooms. The latter are for the convenience of owners, not employees. When a car is brought in, it is first searched, and anything found therein is placed in the owner's locker, the garage and owner having duplicate keys. The second floor is arranged for a ladies' parlor and chauffeurs' quarters, a part of the latter space being a lecture room, in which is conducted an automobile school.

Complete describes the repair shop, located in the well-lighted basement. Aside from tools for doing all manner of repair work, there is a tire repairing outfit, consisting of tube and sectional vulcanizers, recovering plant, etc. A pair of mercury arc converters supply the necessary changes in electric current for charging storage cells in electric vehicles, and for ignition batteries as well, the two being kept separate for these uses.

On the occasion of the recent celebration, prizes were given to the first five automobiles arriving from New York City in a run organized for the occasion.

BRIEF GARAGE NOTES THE COUNTRY OVER

Milton, Pa.—The Ritter Company, an enterprising firm, has opened a garage here, well equipped and managed by experts. It is locatetd at the corner of Arch and Second streets, 64 by 66 feet in size, with front and rear entrances, machine shop, wash stands, underground gasoline storage, etc. The agency for the Jackson, E-M-F and Locomobile cars, as well as numerous sundries, is held. The members of the concern are: E. E. Ritter, who built the first automobile owned in the section, thirteen years ago, which is still in use; Thomas E. Spangler, a local business man, and W. H. Hackenberg, an attorney. The company is a Pennsylvania corporation.

Fond Du Lac, Wis.—The common council of Fond Du Lac has passed an ordinance requiring all garages to be made fireproof, present buildings rebuilt and new ones according to code. It was at first decided to condemn all garages in the business section, but this met with too strong opposition. The ordinance is the result of a recent $250,000 conflagration which is thought to have been started in a garage.

Petersburg, Va. — Plans have been completed for the erection of a fireproof garage for the Stratton & Bragg Company, on its lot on Union street, near Washington. The building will be 60x100 ft. in size, constructed entirely of concrete, brick and steel, and will be fully equipped for the garage and automobile sales business. The company also intends to build on the lot next to the garage a modern and complete brick and steel machine shop, and to install the best machinery. A traveling crane will be a valuable facility.

Fort Worth, Tex.—The Reid Auto Company has found it necessary to build an addition to its quarters at Rusk and Eighth streets, and work has commenced upon an additional story, which will give 9,500 square feet of floor space. Four taxicabs have been ordered and are now en route from the factory.

Springfield, Ill.—Glenn D. Smith is building a thoroughly modern garage at 413-415 South Fourth street, in connection with an apartment house, the latter occupying the front. The garage will be 60 by 80 feet in size, constructed of brick and stone, and fitted with a complete machine shop.

St. Louis—The Albert Sterne Motor Car Company has received permission to construct a large garage building on Olive street, west of Sarah street, with a 50-foot front and 155-foot depth. The plans show that it will be one of the most complete in the city.

Bucyrus, O.—The Bucyrus Cycle and Automobile Company garage has changed hands, Frank B. Lauck succeeding John Eberhard and son in proprietorship. They will have the agency for the Mitchell and Maxwell cars.

Fond du Lac, Wis.—Popularity of garage building has been shown in the receipt of ten bids for the construction of the Anderson garage, at the corner of West Second and Macy streets. One of $4,235 will probably be accepted.

Binghamton, N. Y.—Ellis W. Morse & Company, agent for the Overland cars, is planning to erect a handsome garage, including salesrooms and other conveniences. Several sites are now under consideration.

Vincennes, Ind.—The Johnson Auto Company has leased the old Coliseum building, and will turn it into a garage, first putting in a new front, and then making other decided improvements. A long term lease has been taken.

Los Angeles, Cal.—W. P. Bosbysell, the local agent for the Dorris car, is erecting a new garage on South Olive street, and expects to occupy it within a few weeks.

Wilkinsburg, Pa.—The Co-Operative Automobile Company has opened a garage at 605 South avenue in addition to the agency for the Moline cars.

Told in the Progress of the Industry

New York Sporting Goods Company Enlarges Quarters—Owing to a largely increasing business in automobile supplies and camp equipment, the New York Sporting Goods Company has had to enlarge its store. The present location at 17 Warren street has been increased by the addition of the store next door at 15 Warren street, with connecting archways. The automobile and bicycle supplies will be sold upon the ground floor, and the shipping facilities doubled by the use of another basement. Tents and camping outfits will be moved from the third to the second floor and the entire third used for offices. The remaining floors are for storage and repair shops. This company is now in its twelfth year, and its business has grown from a very small one to one with five departments. Each of these has a separate manager, whose accounts are individual, so that the officers can always tell how each one is being run. A large mail order trade has been built up recently.

Blue Most Popular in Pierce-Arrow Colors—The Pierce-Arrow Motor Company has recently had a table prepared to show the color schemes most chosen by purchasers of those cars. Some surprises appeared, especially for those who like to refer to automobiles as "big red ones," and for purposes of comparison the shades were not taken into account. The following is the ranking discovered: Blue, 26.57 per cent; green, 25.04; wine, 21.14; red, 10.88; brown, 6.66; gray, 4.60; black, 1.75; white, 0.31; lead coat only 2.88. The blue received its lead principally in the smaller cars, such as those of 24, 36 and 40-horsepower; while in the 48 and 60-horsepower models green prevailed. For the coming season Pierce-Arrow dealers will have choices from 32 sets of colors.

Fire Inconveniences Kemizite Manufacturers—The office, accounting department and retail salesroom of the Auto Tire Security Company, at 1231 Michigan avenue, Chicago, were slightly damaged by fire on June 30. The actual loss is reported as trivial and the retail department was doing business in a garage three hours after the occurrence. The wholesale department is temporarily located at 1221 Michigan avenue. No stock was lost and, according to the sales manager, C. L. Morgan, the manufacturing plant is intact and operating at full capacity.

Model Company Increases Capitalization—The Model Automobile Company, manufacturer of Great Western automobiles, has doubled its capitalization. The increase was entirely taken up by the present stockholders and none was offered for sale outside. It was decided at the same time to build two additional factory structures, which will give about 35,000 square feet more floor space than at present. Work will be commenced at once.

Selden Company Buys More Ground—The Selden Motor Vehicle Company, Rochester, N. Y., has purchased four acres of ground in Probert street, 650 feet long and extending between the New York Central and the Rochester, Syracuse and Eastern railroads. The details of the new plant have not been made public, but it is understood that the ground will be broken at once.

Portable, Not Portland—Under the head of "Information for Auto Users," last week was described an excellent device for holding electric lights in any position desired, when working with them in the shop or garage. Unfortunately, an error made this appear to have the trade name of Portland, which is not the case, the name being the Portable Wash-Rack Light.

Packard Company Has No Branches—Recently a report was circulated to the effect that the Packard Company would open a branch in Albany, N. Y., but this was confused with the opening of a new garage and sales establishment by the agent in that section, J. A. P. Ketchum. The Packard Company, when asked about this, stated that it has no branches.

Taxicab Factory in Memphis—The Corbitt Taxicab Company has been formed in Memphis, Tenn., to manufacture and operate taxicabs. A new factory will be obtained to employ 200 men. The cars will be of conventional type.

NEW DIAMOND DEMOUNTABLE

Carrying extra tires inflated and ready to run, a new demountable rim has been developed by the Diamond Rubber Company, of Akron, O. The rim has just been placed on the market and will have a conspicuous place in the Diamond products for 1910. In design and construction it is both simple and strong and permits the removal of the damaged tire with the application of a fresh one, pumped up and ready for running, in scarcely more time than is required to jack up the wheel.

A notable improvement over the Diamond 1909 demountable equipment is the fact that the rim can be fitted to any automobile wheel felloe of regulation construction without material alteration of the same. No machine work is necessary on the wheel band or elsewhere and any competent blacksmith can, the Diamond Rubber Company states, do the job properly and inexpensively. A further improvement eliminates the necessity of mortising out the felloe to admit the valve stem of the inner tube. A series of wedges fitting between the wheel band and the rim itself take up all possible play and make the fit tight and secure. For the same reason small irregularities, due to dinging of rim or band or other causes, cannot interfere with the rim's quick and easy operation.

Diamond Demountable Rim

The new Diamond demountable will accommodate any standard make of regular clincher tire. The Diamond Company has spent much time and energy in developing and testing this new product and the vigor with which the rim is being pushed is plainly indicative of the company's own confidence therein.

IN AND ABOUT THE AGENCIES

Times Square Branch in Kansas City—Jesse Froelich, of the Times Square Automobile Company of New York, and managing director of the Benz Auto Import Company, has established a branch of the Times Square Company in Kansas City, Mo. As in New York, Chicago and St. Louis, this new branch will handle second-hand automobiles for the Western and Southwestern territory. A site was chosen at Seventeenth and Main streets, and the business will be commenced at an early date.

Maxwell, Philadelphia—The Maxwell output will hereafter be represented in the Quaker City by a factory branch house. The Longstreth Motor Car Company, the local agent, last week transferred its affairs to the Maxwell-Briscoe Motor Company by mutual consent. William F. Smith, general manager of Maxwell district No. 3, will have complete charge of the retail business as well as the wholesale. The present quarters will be retained.

Empire Opens Philadelphia Branch—The Empire Tire Company announces the opening of a branch house in Philadelphia at 322 North Broad street, on Automobile Row. It will be in charge of E. B. Richardson, who in the past has represented the company in the capacity of general salesman.

RECENT BUSINESS CHANGES

Spare Motor Wheel Company Moves Offices—The Spare Motor Wheel Company of America, Limited, has moved its general offices to the factory in St. Anne., Ill., from 236 Michigan avenue, Chicago. The company has taken up the manufacture of standard clincher automobile and motorcycle rims, in addition to the Stepney spare wheels. It is making the Universal demountable rim for the Universal Rim Company of Chicago, and its own rims will be handled through the American Distributing Company of Indianapolis.

PERSONAL TRADE MENTION

Charles Ethan Davis has been appointed the general manager of the Warner Gear Company, of Muncie, Ind. He was formerly with the American Locomotive Company at Providence, R. I., and will take up his new work in the West on August 1.

Ernest L. Smith, of Detroit, has been made sales manager of the Grant-Lee Machine Company of Cleveland. Mr. Smith was formerly Western representative of the Standard Roller Bearing Company.

James E. Murray, manager of the automobile department of the New York Sporting Goods Company, has left the city for a two months' vacation at his camp near Wolfboro, N. H.

TAXICAB AND TRANSIT

Decatur, Tex.—To avoid a trip of 80 miles, via Fort Worth, to go 28 between Decatur and Denton, it is probable that an automobile line will be installed shortly. The traveling salesmen who enter this territory are particularly interested in the proposal and are seeking assistance from the Commercial Club of Decatur.

Carleton, Mich.—It is likely that an automobile bus line will be established between this town, Flat Rock and Rockwood, running on a schedule, and connecting with the Detroit, Monroe & Toledo electric line at Rockwood. Alexander Ropelle, of Detroit, is the promoter of the scheme.

PACKARD EXPERTS CONVENE

Detroit, July 6—Superintendents of the mechanical departments of Packard dealers throughout the country have been visiting the factory of the Packard Motor Car Company for the past two weeks. Meetings have been held daily at which all mechanical features of Packard 1910 cars have been discussed as well as the general conduct of Packard repair work and shop service for owners. The visitors also have spent much time in the factory studying Packard methods of construction and the actual manufacture of the new models. There has been road work in new cars, and the social side of the conventions has taken the form of drives into the country for frog-and-chicken dinners seasoned with shop talk and suggestions for future improvement.

At some of the meetings the executive, engineering, factory, sales and technical heads of the Packard Company have held lively discussions with the visiting experts, thus presenting all features of car design, construction and maintenance from many points of view. In fact, the meetings have been so notably successful that they will probably be made annual affairs.

Most of the Packard dealers' superintendents were taught their business in the Packard factory. It is one of the most important parts of the Packard policy to give efficient service to owners everywhere.

RECENT INCORPORATIONS

Flexible Aeroplane Company, Newark, N. J.—Capital, $100,000. To manufacture aeroplanes, automobiles, etc., etc. Incorporators: J. Formanna, J. K. Murgatroyd, H. Taylorson.

Eastern Auto Transit Company, Albany, N. Y.—Capital, $35,000. To operate stage line between Albany and Schenectady. Incorporators: W. A. Cryne, E. D. Wintersteen, C. B. Henry.

Badger Motor Car Company, Columbus, O.—Capital, $100,000. Incorporators: E. W. Arbogart, W. C. Leitsch, George C. Holtz, A. M. Bellack, E. M. Poser.

Barber Auto-Cab & Repair Company, Brooklyn, N. Y.—Capital, $15,000. To manufacture automobiles, etc. Incorporators: A. S. Barber, R. A. Rendich, William Barber.

RECENT PUBLICATIONS

Ferro Machine and Foundry Company. "Marine Gasoline Engines and Equipment"—This differs from the ordinary catalogue in many ways. Fundamentally it is a treatise on the correct design, construction, installation and operation of power boats. Being intended primarily for the man who is not a mechanic, it is written in simple, non-technical language. The first edition was issued in 1907, and the present work is that brought up to date by the additions of last year and the more important ones included within the covers for 1909. After some pages of general information on principles and historical review the details are taken up in order, beginning with the carbureter. Ignition and mechanical parts follow in order, much space being devoted to a praiseworthy attempt to elucidate the mysteries of the former. After that considerable mention is made of the shop processes, this being of value to the purchaser in that he ought to know of the painstaking care necessary to produce the ultimate result, the finished motor. The illustrations throughout are very complete and well done.

American Manganese Bronze Company, Holmesburg, Pa.—This is a small folder descriptive of the company's product which consists of bronze and allied metals. The principal product to which most of the folder is given up is manganese bronze, well known for its great strength, forgeability, ease of casting allowing complicated shapes to be cast of it, and bearing value which permits the use for bearings to a limited extent. The trade name of the metal is Spare's, and the guaranteed tensile strength is 75,000. A series of accurate test records is given in which the lowest figure reached therein is 81,500 pounds, and the highest going up to nearly 85,000 pounds.

In addition, a bearing metal of white bronze is made, this being a true bronze and not a babbitt metal. This combines with great strength a high melting point, and other valuable properties, fine anti-frictional properties. In fact, the makers are ready to promise and guarantee a coefficient of friction below .01 with properly fitted shafts and bearings.

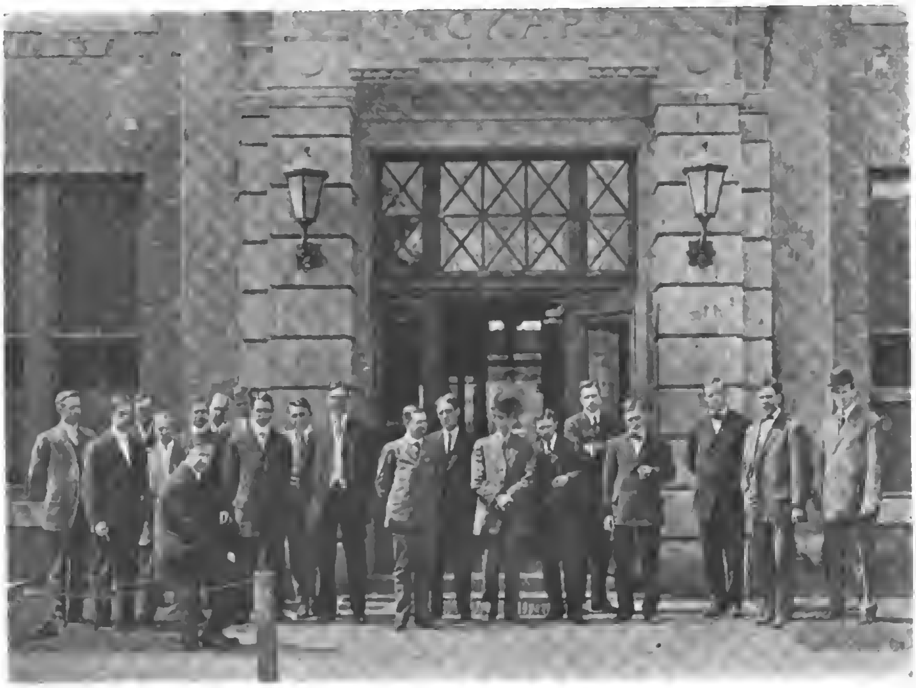
Vehicle Top & Supply Company, St. Louis—Vesco tops for all kinds of automobiles are made by the Vehicle Top & Supply Company, of St. Louis, and illustrated in the latest catalogue issued by this concern. Best known under the trade name of Vesco, these tops are made in several varieties of material and design. There are four kinds of fabrics named—Pantasote, Vesco, "Auto" rubber, and cravenette and mohair, with the advantages in respect to price of each compared and the quality described. The cravenette and mohair tops are the most expensive, with the Pantasote, Vesco, and "Auto" rubber ranging in that order. The details of lining are also described at length in regard to each style and price. The company also manufactures lines of tire covers, dust covers or hoods, lamp covers, wind shields, and makes a specialty of automobile body upholstering.

G. H. Curtiss Manufacturing Company, Hammondsport, N. Y.—Curtiss motorcycles of one, two and three cylinders are described in an interesting catalog just received. The details of the roller bearing motors, the trussed frame and fork construction, are considered, and the specifications of the five types given. Views of the flexible side car and of the rear seat attachments are shown. The single-cylinder models are fitted with 3 and 3½-horsepower engines; the two-cylinder machines with engines of 6 and 7-horsepower, and the three-cylinder, one with an engine of 10-horsepower, geared to give a speed of 90 miles per hour.

Syracuse Rubber Company, Syracuse, N. Y.—One of the most complete catalogues of automobile sundries published for the 1909 season has recently been issued by the Syracuse Rubber Company. In handy size for carrying in a pocket of an automobile, it may be used as a reference book, for practically everything in the accessory line has been listed. For the autoist who is equipping a new car or for the owner who desires new supplies the booklet will give prices and description of the various articles. Motor boat and yacht supplies are also given detailed attention.

International Acheson Graphite Company, Niagara Falls, N. Y.—A new folder just issued is known as 273 J. It is descriptive of their graphited greases, products which are designed for gear, cup and ball-bearing use. In the manufacture of their graphited grease this company uses the purest and best graphite. The graphite and grease are well blended, and it is claimed that the resultant product will show a tremendous amount of working force, great value being given the combination by the superior lubricating qualities of the graphite.

Southwestern Automobile Supply Company, Dallas, Tex.—From the far Southwest comes a complete catalogue of one of the largest automobile supply distributors of that territory. Inasmuch as automobile factories state repeatedly that the largest sales of autos are going to Texas and the States immediately bordering upon it, the supply business has taken a prodigious growth, as the book of the Southwestern Automobile Supply Company proves. All lines of accessories are mentioned with prices.



Convention of Packard Service Department Superintendents

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, JULY 15, 1909—CHICAGO No. 3

THE AUTOMOBILE

DETROIT GIVES GLIDDENITES ENTHUSIASTIC SEND-OFF

Mayor Breitmeyer Fires the Starting Gun

Where Start was made from, Hotel Pontchartrain.

Detroit The City Beautiful.

DETROIT, July 12—To the fanfare of trumpets (supplied by the Maxwell-Briscoe band), the booming of cannon (touched off by Mayor Breitmeyer), and the waving of banners (done by the hospitable citizens of this automobile-making town), the sixth tour of the American Automobile Association had a vociferously successful beginning at 10 o'clock this momentous July morning. Forty-two cars were soon on their way, two having preceded the main body: Pilot Dai Lewis with the confetti and Chairman F. B Hower in the pacemaker's role. Thirteen are contenders for the individual temporary possession of the Charles J. Glidden trophy; fourteen are seeking ownership of the Hower cup; and only three are rivals for the beautiful Detroit prize The remaining dozen are divided into official, press and general supply cars

A PARADE OF AUTOS THAT TOLD ITS IMPRESSIVE STORY

DETROIT, July 12—One thousand and thirty automobiles to-day took part in the greatest automobile pageant ever held—a part of the Glidden tour preliminaries—and the line extended over a course ten miles in length. Combined with this almost phenomenal turn-out were the hundreds and hundreds of touring cars and roadsters parked along the route. The owners and manufacturers of the city had promised to give a spectacle that had never been equaled, and they succeeded.

But not alone in numbers did this event surpass previous affairs of its kind, but also in the matter of decorations. The opinion was unanimous that never before has there been such a motor-driven galaxy of the wonderful and beautiful. Electrically, gasoline, and steam-driven cars participated; and cut flowers, artificial ones, ribbons, satins, birds, and all imaginable forms of decorations were in evidence. Indeed, so much painstaking labor had been put upon those who were competing for the handsome prizes that the judges, persons well able to discern harmony of coloring, were at great loss. In some cases the victor in the divisions was cause for deep pondering. Sufficient handsome rewards had been offered to make competition well worth while, and consequently the prize list was long and contenders most plenteous.

Cadillac was the fortunate one in the class for the most artistic float or decorated car in the parade, and its representative was from the factory. This was a float built to depict the landing of Cadillac. The car had been fashioned into a large boat, in the bow of which stood Cadillac, a large banner in his hand. Back in his craft sat a number of Indians in their full tribal regalia, and so deftly had the construction been planned that the driver of the car was invisible from the exterior, just this little touch giving the whole float a gliding effect. In the same general class was a "Lady's special," and, with a diamond and ruby ring to be presented, this will be awarded later.

The parade was started at about 1 o'clock, ran through the center of the city, and out to Belle Isle Park, where the actual judging took place. When the entire number of cars had assembled on the green, a view was presented which has had no equal. Impressive as was the length of the event, in passing a given point downtown, it was even more so when the machines were banked and massed, scores of rows deep. Electrics took the lead in the contesting division, although the police squad elicited no little comment. Four little Maxwell Junior runabouts, each carrying one officer in addition to the driver, cleared the streets instead of the more conventional platoon of horsemen.

The Anderson Carriage Company seemed to have turned loose a month's output, perhaps, for it was stated that the value of the half-hundred Detroit electrics was close to $125,000. The Columbus electrics were also well represented, as were other standard makes. The count of the various makes was not authenticated, but it was stated around headquarters in the evening that Cadillac and Brush led with about 80 cars each. Chalmers-Detroit, Packard, Regal, Maxwell, E-M-F, Hudson and Rapid were not far behind, however, and all had more than a dozen apiece. So many of the 400 decorated cars were so well disguised that it was almost impossible to tell at a glance just what make they were. The features of the cars are too numerous to mention, and a few must suffice.

One that attracted considerable attention was a float entitled "The Spirit of '76," and was a representation of the famous painting. Dr. E. B. Smith furnished the outfit, importing a veteran trio which could fill the parts. The local fire department was on hand with its "flying squadron," holding second place in line. The Morgan & Wright Company had a particularly comprehensive display, using four large trucks to show the details of making a rubber tire. First was a scene snatched from the tropics, with a number of boys of color gathering the

Ten Miles of Automobiles in One Picture; as the Thousand Odd Machines of the Pre-Glidden Tour Parad

Chairman F. B. Hower, of the contest board, the principal speaker of the evening, did more than spat some of his hearers on the wrist. He rapped them across the knuckles in a way that left the only sting in the entire program. Chairman Hower was disappointed at what he chose to construe as apathy on the part of many manufacturers, and he did not mince his words in giving expression to his displeasure.

"If anyone had asked me at the outset how many cars we would have in the tour this year," said Mr. Hower, "I should have guessed 125. We all guessed that. Then came the revelation. I began to receive letters from manufacturers all over the country who found that they could not enter the tour. The reason? They were enjoying too much prosperity. They couldn't see where they were going to gain anything by entering the tour when they were unable to fill the orders they had. So we have fewer cars than we expected.

"I tell you, gentlemen, that this auto business may be to the

Banquet Tendered A. A. A. Officials by the Detroit Auto Dealers' Association, at Hotel Pontchartrain, July 9

r an industry. To us who own and drive cars it is e are interested in these contests for the sport they not say those manufacturers who made excuses were e sporting chance. That would be unfair to them. not enter; and I tell you that we must keep up the of the industry if we wish to maintain the industry

criticised for what I am saying, but I do not care. e to promote the industry, but to promote the sport ests. I say that those manufacturers who did not ur hurt themselves, not us, for the Glidden tour ogress of the automobile. Those who are unwilling t progress they have made are hurting the industry,

of surprise followed Chairman Hower's remarks, inly that many of his hearers were not in sympathy mistic view he took of the situation, but no further the incident was made.

Hower was presented by Mayor Breitmeyer with a o the city. The Mayor dwelt at some length upon the industry and what it has done for Detroit, welcoming the tourists and other guests in a happy manner.

President Speare, of the A. A. A.; Charles J. Glidden, donor of the trophy which is the prime cause of the tour; George C. Diehl, of Buffalo, good roads advocate par excellence; Horatio S. Earle, former Michigan highway commissioner; Hugh Chalmers, of the Chalmers-Detroit Motor Car Company; Benjamin Briscoe, Col. Pardee and others were also on the toast list, which was an extensive and too prolonged one, and in which all the participants vied with each other in saying kind things about everybody elsse.

President George Lane, of the Detroit Auto Dealers' Association, was toastmaster, and contributed much toward making the event the enjoyable affair it proved to be. The banqueters departed with warm appreciation for the hospitality and public spirit of the Detroiters, and all joined in the wish that they might meet again in the city "where life is worth living."

DETROIT ENTERTAINS A. A. A. DIRECTORS

One of the most successful social functions preceding the start of the tour was the dinner given by the Automobile Club of Detroit to the directors of the A. A. A., the affair taking place Friday evening at the picturesquely situated country clubhouse at Pine Lake. President C. H. Hecker made a versatile toastmaster, and under his skillful suggesting the orators kept themselves in condensed form. President L. R. Speare and Chairman F. B. Hower spouted some about the A. A. A., but more about the hospitality of Detroit, to which S. A. Miles, Alfred Reeves, Col. F. M. Joyce, Thomas Henderson and A. G. Batchelder added other hunks of appreciation. Ex-President Edwin S. George said the club was glad to have such thankful guests.

Intermingled with the occasion was the formation of the Aero Club of Michigan, of which W. E. Metzger was elected president and compelled to supply a verbal acceptance. Since Charles J. Glidden is becoming a well-known aerial traveler his presence naturally brought about some words of aeronautical complexion. It was midnight before the 26-mile return to the city via autos had landed the banqueted ones at the Hotel Pontchartrain.

Little Parade All of Their Own—The 625 men of the jolly party that went down on the *Cleveland* Sunday formed lines on the return and marched to the Pontchartrain in two lines with a number of autos in the center.

Pilots and More Pilots, But No Sky Pilots—The confetti car, for the first time, was backed up by a second car for the 1909 tour. Dai Lewis, chief pilot, and Marc Reeves, second to Lewis, captained the two cars.

New Model Haynes Cynosure of All Eyes—Elwood Haynes, the pioneer of motordom as a business in the United States, ran over from Kokomo in the 1910 Haynes, which drew immediate attention.

Many Scribes on Hand—The press of the country took interest in the tour, for over sixty press men appeared in Detroit for the tour, an average of 1½ for every car in the run.

Pierce Patten Promptly Appeared—"Bob" Patten, of the sales force of the Pierce Company, could not remain away, so made the run over to see the Pierce cars well under way.

Lots of New Models Shown—Quite a number of 1910 cars, including two Packards, were seen on Detroit's streets. The Chalmers had out their models also.

Matson Gets a Job, Too—Joe Matson, winner of the Indiana Trophy race, went out as an observer for the Chalmers-Detroit team.

Yellow Kids Once More—Morgan & Wright's Yellow Kids were in evidence at every turn, and attracted general attention.

TIRE MANUFACTURERS WILL BOOST PRICES

Circular letters have been sent out by practically every tire manufacturer in the United States announcing an increase in prices of from 15 to 25 per cent., to take effect July 16. The circulars were received by automobile manufacturers and dealers in New York last Tuesday, and on the same day a number of tire dealers on Automobile Row posted bulletins in their windows calling attention to the change. According to the tire-makers, the raise is due principally to the increased price of crude rubber, which has nearly doubled within the last three months. The makers, it is said, have held several secret meetings at Cleveland and Okron, O., at which the leading men of the industry were present, and judging from the uniformity of their announcements, they have come to a good working agreement. As it has been obvious for some time that the makers' profits were being seriously cut into by the soaring price of rubber, their action did not come as a complete surprise, except that the raise is larger than was anticipated.

DELAWARE'S NEW LAW IS RECIPROCAL

Wilmington, Del., July 12—Delaware's new automobile law going into effect, the police department of this city has been instructed to arrest the drivers of all machines found on the city streets without Delaware license tags, except those having tags of States which permit visiting machines to pass through without local licenses. This will be particularly hard on the neighboring States of Pennsylvania, Maryland and New Jersey, which do not extend this courtesy to visitors. The Delaware law contains a reciprocal clause, which extends the same courtesy to other States as those States accord visitors.

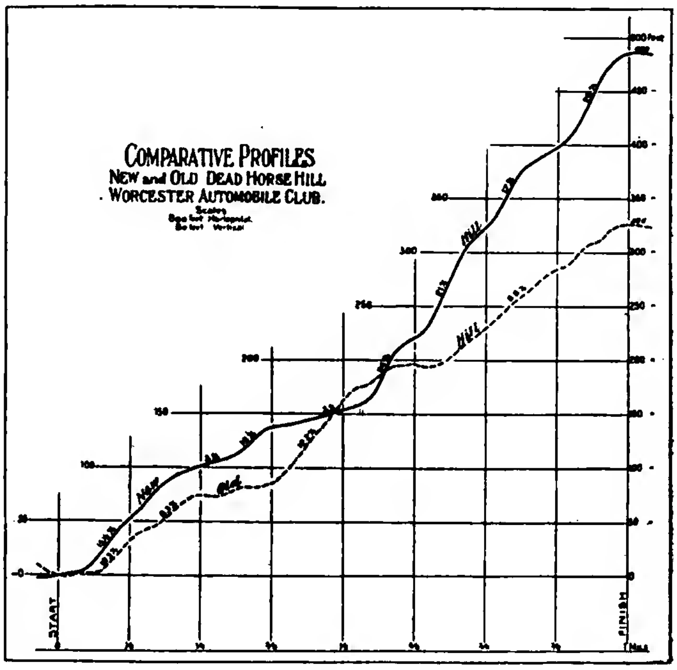
GARAGE RESTRICTION PLANNED IN OHIO

Columbus, O., July 12—Chief Lauer of the Columbus fire department has prepared an ordinance to be introduced in the city council soon for the purpose of regulating garages. It provides that no garage shall be more than one story high, and that the structure be built of fire proof material. Signs prohibiting persons from smoking in the garages must be displayed. The storage and use of gasoline as well as the care of electrical wires are to be regulated. The ordinance is regarded as too stringent by garage managers.

WORCESTER WILL BUILD A REAL HILL

Worcester, Mass., July 12—For hill-climbing contests hereafter, the Worcester Automobile Club will have a course with nearly ideal conditions, embodying some new and popular features. Principal ones are the erection of the grand stand at right angles to the road, and over it, so that the spectators can see the cars approach, and dash right under them; and another point which no other hill in the country will have is a roadway wide enough for its entire length to have two cars climbing at the same time.

The plans for the construction of this rise have been about consummated, and of the $20,000 necessary, present subscriptions amount to $6,000, and the remainder is all in sight. The course is some distance from the old Dead Horse Hill and will have to be built from start to finish. Surveyors have completed their work of laying it out and actual construction will be commenced at once. It is expected that it will be ready for use early in



October, and the hope is to have the national event here next Spring. After the grading is completed the hill will be coated with Hassam pavement, the same as on the Long Island Motor parkway. The width will be amply sufficient for starting two cars abreast, and the people on the grand stand will be able to see them for three-quarters of the mile length. The rise will be 489 feet, with grades varying from two short dashes of three per cent each to one at the finish of 25. The average is about 15 per cent, lowered by the places where the road is not steep. The ascents of 24, 21, 17, and 25 per cent will be thorough tests for the cars. The old Dead Horse Hill rises but 325 feet in the mile.

COUNTERFEIT TAGS USED IN OHIO

Columbus, O., July 12—The motorcycle brigade of the Columbus police force recently arrested one of the drivers of the Columbus Buggy Company for carrying on his machine a tag not furnished by the state automobile department. There was no charge that the motor car was not licensed, but rather the arrest was made because of the use of a fictitious tag. Some days ago the attention of an officer was called to the tags used which were made by the company, the same number as that on the state tags being used. The driver claimed that he could not use the state's tag on the automobile. A similar state of affairs exists in Dayton also and the state automobile department is determined to eradicate the evil.

Functions and Frailties of Motor Cylinders

By Thos. J. Fay

DESIGNERS take advantage of the properties called "chill," in connection with cylinder work, by the simple expedient of limiting the thickness of "finish" as shown in Fig. 15, so that the dense material, as indicated in the sectional drawing, Fig. 16, of a cylinder is not all cut away in the finishing process. The strength of a cylinder, if dense material is left on the inside, as well as the "skin," on the exterior, will be greater than when the cylinders are finished all over to a depth sufficient to uncover the gray iron section; gray iron, with a covering of white iron, which is very possible to realize, if the charge in the cupola is well regulated, and if the depth of finish is adequately limited.

Some Properties of Gray Cast Iron—Gray cast iron, in the sense that it is referred to here, is a remelt, in a cupola, of suitable grades of blast furnace pig iron. The gray variety of cast iron is that holding such an excess of graphite as to conceal the iron from view in the fracture. It is a foundry problem to arrive at the desired result by suitably mixing the material for the charge in the cupola. The components in cast iron are iron, silicon, sulphur, phosphorus, manganese, combined carbon, graphitic carbon and more or less "slag."

Unlike in steel, sulphur and phosphorus are held at a fairly high limit, although, as in steel, these elements have a weakening influence on the strength and endurance of the product.

In general, the limits to be put on the elements entering into castings for cylinder work may be set down, viz.:

Combined carbon, maximum, 0.75 per cent.
Silicon, maximum, 1.20 per cent.
Sulphur, maximum, 0.085 per cent.
Phosphorus, maximum, 0.50 per cent.
Manganese, maximum, 0.75 per cent.
Slag and oxides to be almost completely eliminated in practice.

It will be understood that, in practice, the components range at variance with these maximum values, and in fact silicon generally exceeds the limit set, notwithstanding the lowering of tensility, but it also affords fluidity, which is a much needed quality in cylinder irons, in view of the thin walls.

In fairly good castings the silicon content is likely to run about 1.60 per cent., but even this value will show a decline of the tensile strength, although good sound castings must rank first, and it is customary to assume that cylinders should have a minimum value of the tensile strength of 18,000 pounds per square inch, which value may be exceeded with silicon at 1.60 per cent.

Right here it may be well to point out that claims of even 35,000 pounds per square inch are frequently made for cylinder castings, and few will admit that the strength should be less than 26,000 pounds per square inch. At all events, it matters not what the strength may be in isolated cases, since none will guarantee every casting, and safety demands that the minimum value realized be taken as the maximum to figure on in practice.

If in gray cast iron the total carbon is upward of four per cent, it is at once plain that graphite will be present in considerable excess, because, in the nature of the product, combined carbon will be far below the point of chemical absorption of all the carbon present. The graphite present is indirectly an indication of softness in proportion as the amount shows in excess, but it is something of a fallacy to attribute this softness directly to graphite. Softness and ability are due to a small amount of cementite and relatively a large amount of ferrite rather than to a large excess of graphite. If, then, the total carbon is a constant, the soft iron will show a large excess of graphite because the total combined carbon will be low, and if this condition obtains, the ratio of ferrite to cementite will be more nearly in

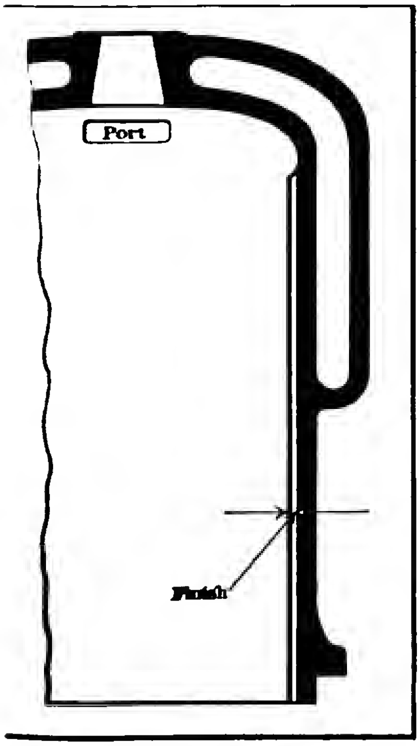


Fig. 15—Section, showing the finish allowance in the bore of cylinders stopped off at end of stroke

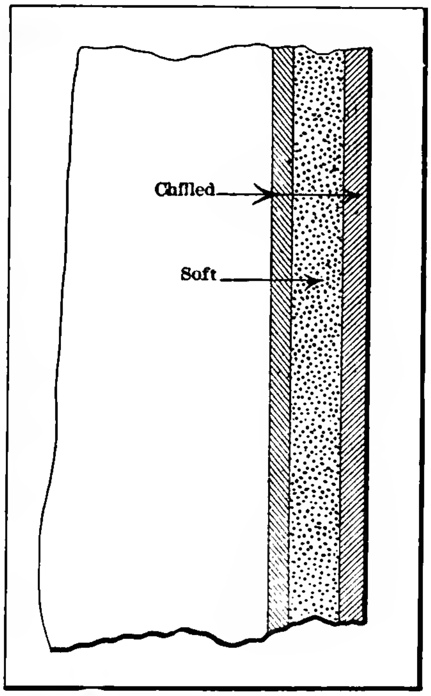

Fig. 16—Section, indicating the hardness of exterior, and soft interior of gray cast iron with slightly chill surface

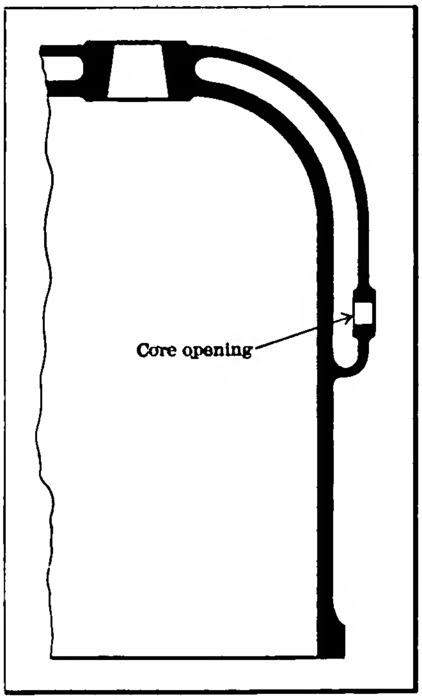

Fig. 17—Section, showing core-hole, by means of which the core is suspended in the process of casting

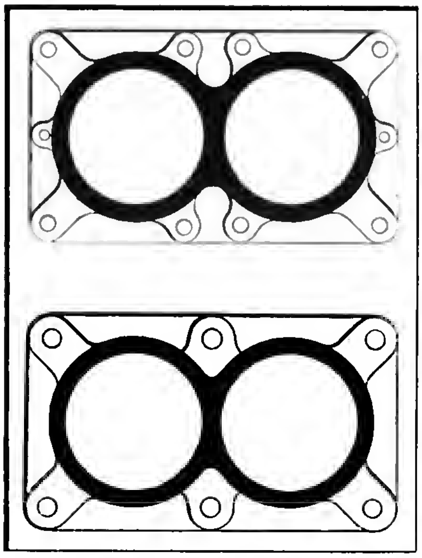

Fig. 18—Sections, showing bolting plans twin-cylinder construction

accord with the best requirement. True, graphite itself is of low strength, and an excess of graphite enmeshed in the matrix must have its weakening effect, but the difference between cast iron and steel lies in this fact.

Fixed carbon in cast iron for cylinder work should not exceed 75 points, and any increase in the fixed (combined) carbon above this point will be at the expense of excess ferrite, because this excess decreases as the total combined carbon increases, which to illustrate an example may be taken involving, say, 75 points, combined carbon.

Hence:

$.75 \times 15 = 10.25$ cementite.

And

$10.25 \times 6.4 = 65.60$ ferrite.

Therefore:

$65.60 + 10.25 = 75.85$ pearlite.

And

$100 - 75.85 = 24.15$ per cent. = excess ferrite.

At a glance it may be seen that by increasing the combined carbon to 75 points the excess ferrite fell off 24.15 per cent., whereas with the 45 points carbon the excess ferrite was 50 per cent.

The effect of graphite will best be illustrated by making a comparison, with combined carbon on a common basis, as follows:

TENSILE STRENGTH IN POUNDS PER SQUARE INCH

Fifty carbon steel, 105,000.

Fifty combined carbon cast iron, 25,000.

True, the tensility of the respective products might vary over broad ranges for various specimens and reasons, but the relation hold, nevertheless, for both products can be varied equally. Cast iron, holding about 10 points of combined carbon, would have a tensile strength of not far from 15,000 pounds per square inch, if the total carbon be the same as in the case of the 50 points of combined carbon above cited. In this an illustration of the ills of excess graphite is quite apparent, since a loss of 2-5 of the tensile strength is a good approximation.

Any attempt, then, to solely attribute good qualities and softness to excess graphite must be regarded as on slim grounds, nor would low combined carbon be a desirable condition. What seems to be best is that quantity of combined carbon holding excess ferrite about equal to pearlite, and if this contention can be substantiated, carbon (combined) should not exceed 50 points.

Phosphorus causes lack of ability to combat shock loads, which is more apparent with high combined carbon than with low, so that decreasing phosphorus should be the rule with increasing combined carbon.

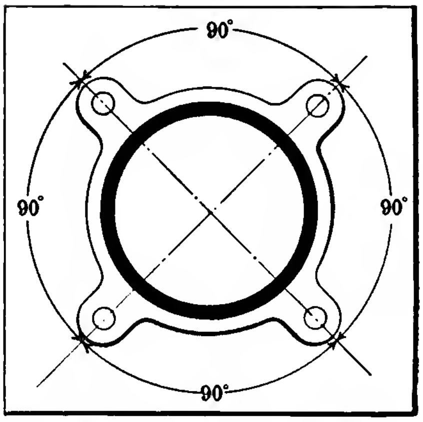

Fig. 19—Section, showing bolting plan of individual cylinder construction

Sulphur usually ranges between 0.04 and 0.16 per cent. It should not exceed 0.085 per cent. in the class of castings under discussion, and would be better at a limit of 0.06 per cent. Sulphur tends to hardness and hot shortness. Fortunately, sulphur is bound to be low with any considerable amount of combined carbon. Increasing silicon, as well as holding the combined carbon up to a fairly high value, aborts the evils of sulphur, as well as limiting the amount. If the pig and scrap and perhaps the fuel are high in sulphur, the carbon and the silicon are likely to diminish, and on this account, with high sulphur, low carbon and silicon may follow, although silicon, notwithstanding this fact, generally ranges higher than the limit put upon it from the purely strength point of view. "Chill" and a tendency to whiteness comes with high sulphur and without high silicon to match, and the castings with such characteristics are likely to be inferior.

The hardening tendencies of silicon are not rendered apparent unless it is in excess, because the softening effect of the lowering combined carbon exceeds the hardening tendency that silicon exerts. An excess of silicon favors an increase in shrinkage, since shrinkage increases with hardness.

Manganese increases the saturation limit of carbon in the molten mass, masks sulphur, and is itself a mild intensifier as compared with carbon. In automobile cylinders this element seems to be valuable above 0.75 to 0.80 per cent., while on the other hand it rarely reaches 0.80 per cent. in cylinder castings.

The saturation limit of iron for carbon may not exceed 4.5 per cent., and it is generally less. One would expect, then, a low total carbon with low manganese, and an inspection of numerous determinations bears out this fact as follows:

Total carbon, 3.00, 3.50, 4.00.

Manganese, 0.20, 0.40, 0.80.

These values are not invariable, because other conditions alter the stability of the composition, but they do illustrate the point, *i. e.*, low manganese denotes low total carbon and vice versa.

The tendency of manganese is to produce brittleness, and while chill is not due to manganese directly, it is likely to induce a condition of hardness that will result in excess chill under certain conditions; shrinkage is also increased in the presence of excess manganese.

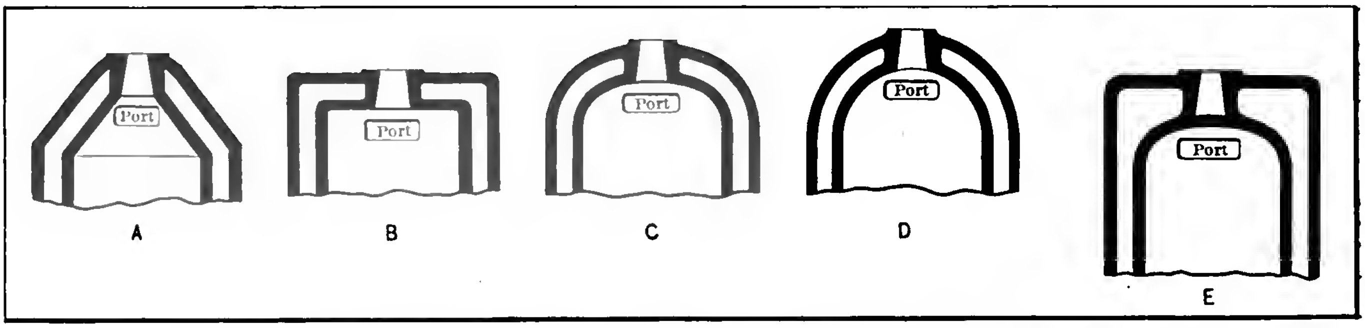

Fig. 20—Illustrating several conventional shapes of cylinder domes, as used in automobile motors

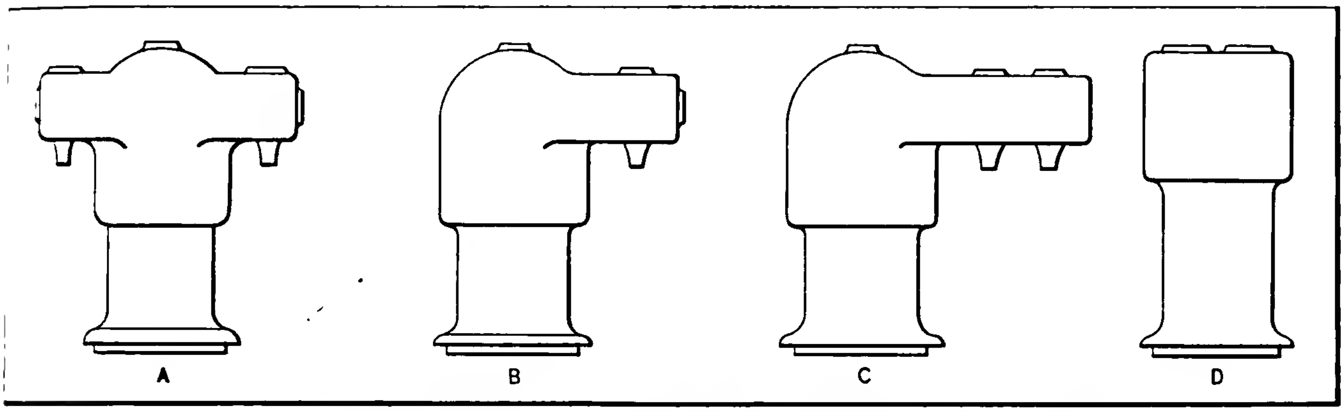

Fig. 21—Depicting the several forms of cylinders as distinguished by locations of valves

Influence of Quality of Castings on Dimensions—The precision demanded in cylinder work, and the lightness desired, tend strongly to the conclusion that no design involving a nicety of proportions will be a round success unless the quality of the material is definitely fixed upon. The discussion as here indulged in is with the idea of suggesting the formidable nature of the problem, if the designing effort is limited to dimensions and shape of parts, without considering the characteristics of the material to be used. If shrinkage is not approximately up to the figures assumed in making the patterns, the walls of the cylinders will not be of the thickness figured upon; if the metal is brittle, high compression will result in disrupted cylinders, especially if thin walls are made, on the ground that light weight is sought for.

In an attempt to realize lightness, and to avoid shrink holes and other defects, the bosses are reduced to the lowest possible mass, and the danger is in the direction of leakage, from lack of bearing of plugs, covers, etc., as illustrated in Fig. 17, of a core holes, of which there must be a certain number disposed at advantageous points around the cylinder, for the purpose of holding the cores in place.

Flanging at the Bottom Demands Secure Bolting—When cylinders are cast in pairs the flanges have to be faced off, and centering is accomplished by approximate methods by the workman rather than by having a bottom extension fit into a recess in the crank case. The flanging is in the nature of a bottom connection between the cylinders, and unless the bolting scheme is well thought out there is danger of deformation, with possible rupture of the cylinders. Fig. 18 shows two schemes of bolting, one of which with six holding points and the other with ten holding bolts; the latter is to be preferred if the cylinders are large, and the diameter of holding bolts should be adequate for the purpose, having in mind the nature of the stresses that may be put on the section of the bolts by the mal-use of big wrenches rather than the pull due to working pressure, and the desire to abort deformation of the flange connection between cylinders. Fig. 19 illustrates flange bolting when cylinders are individual, and if the bolts are 7-16 inches in diameter the plan leaves little to be desired. On the bolts of a cylinder six inches in diameter, if the maximum pressure is 300 pounds per square inch, the total pressure will be equal to:

$$P = d^2 \times \frac{\pi}{4} \times p = 6^2 \times \frac{\pi}{4} \times 300 = 8{,}481 \text{ pounds.}$$

If four 7-16 inch bolts are used, the pressure per square inch on the section of each bolt, in tension, will be:

$$s = \frac{p}{4 \times 0.1503} = \frac{8{,}481}{4 \times 0.1503} = 13{,}940 \text{ pounds per square inch.}$$

and,

P = Pull in pounds, exerted by the cylinder, on the holding bolts.

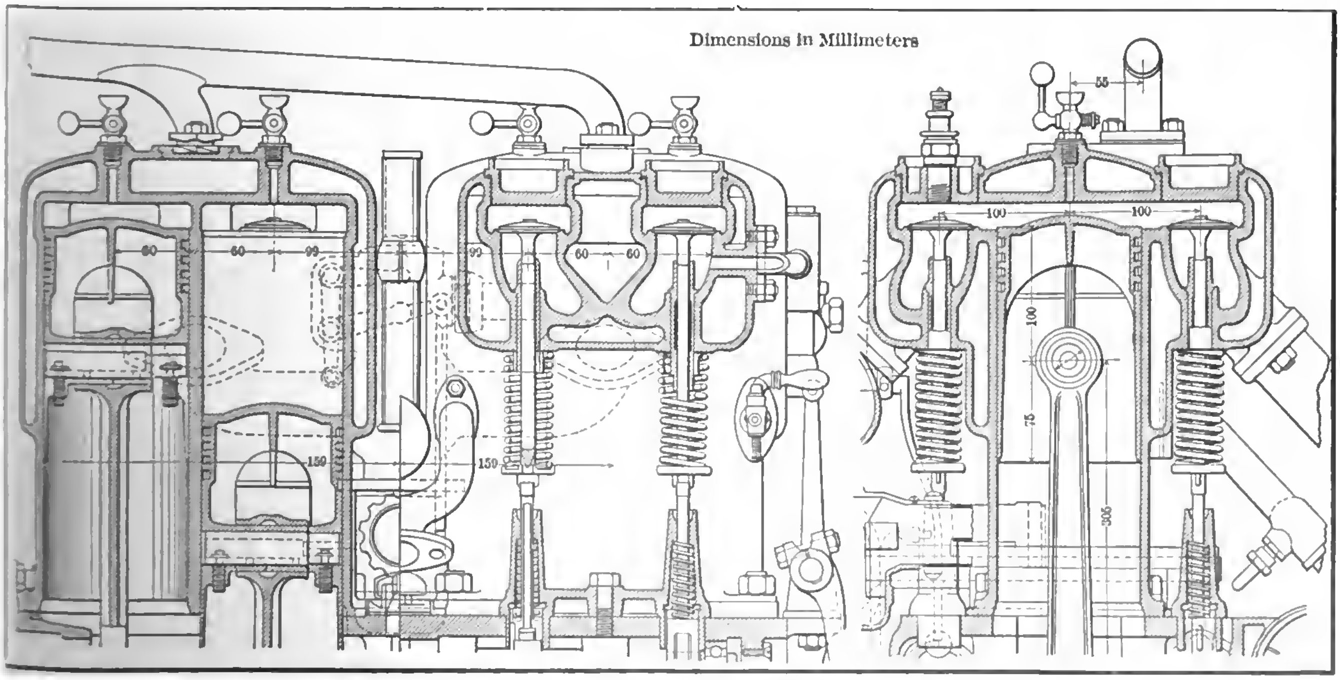

Fig. 22—Four-cylinder motor, in cross and longitudinal section, showing proportions and location of T cylinders

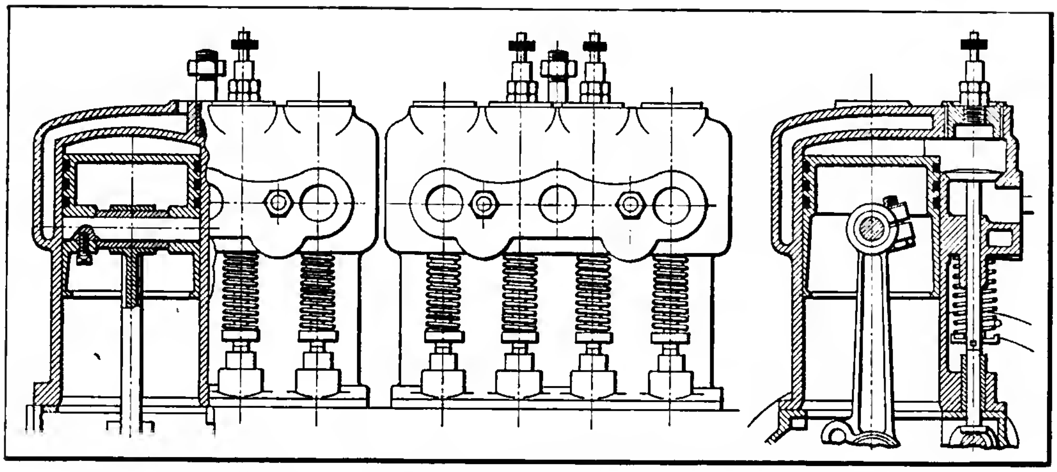

Fig. 23—4-cylinder motor, in cross and longitudinal section, showing L cylinders in place, and spacing between them

p = maximum pressure per square inch of the gas in the cylinder.

d = diameter of cylinder bore **in inches.**

s = strain on the section of one bolt, in pounds per square inch, in tension.

0.1503 = sectional area of one 7-16 inch bolt, counting from the depth of the thread; if the thread cuts below this diameter, the difference must be taken into account. The ability of the material of which the bolts are to be made must be considered, and if it falls below the value found for the strain, it will be necessary to add to the number of holding bolts; as a rule, materials for this work will sustain under 16,500 pounds per square inch as a low limit, which includes an adequate factor of safety, assuming the ultimate strength of the bolt stock to be 65,000 pounds per square inch.

Shapes of Domes Influence Results—It has been found, as a result of many tests, that the mean pressure in cylinders—considering a given fuel, equal methods of cooling and other conditions on a constant basis—will differ, depending upon the shape of the dome of the combustion chamber. Fig. 20 illustrates the several shapes in vogue, and referring to A it is to note a truncated cone, offering great strength, and relatively little surface between the combustion chamber and the water, or other cooling medium, on the exterior surface of the cylinder wall; B depicts a flat head, the surface of which is rather more than in that of curved shapes, and the strength of the head is the least of all; C represents an elliptic curvature, frequently adapted in high compression motors in order to restrict the volume of the combustion space; D is of a semi-sphere, offering the advantage of minimum surface to the cooling influence and strength to the greatest possible extent; E is offered for the purpose of showing that the exterior shape may be different from the interior, providing that adequate water volume is allowed for, which is one of the advantages attending this particular design.

On account of the influence of the valve ports, especially when they are located at the side, it is difficult to determine the relative surface for the several shapes without first considering the surface that follows the contour of the valve ports. As a primary consideration, it is necessary to establish the clearance volume, in view of the desired compression, and then the shape of the dome will work in, with influences for efficiency, depending upon the surface offered, remembering that decreasing surface is in the direction of increasing thermal efficiency. Mean pressure, hence power, increase with an increase in thermal efficiency also.

Considering Conventional Shapes of Cylinders—Referring to Fig. 21, A represents the T type of cylinder; B, the L type, with valves in the axle plane; C is of the L cylinder, with inlet and exhaust valves in the lateral plane, and D represents a cylinder with valves in the head, thus eliminating offsets. T cylinders are much used, and Fig. 22 shows this type in position, indicating relative proportions, as they obtain in good practice involving a four-cylinder motor. Fig. 23 depicts an L type of cylinder, showing the arrangement and relative proportions, in a four-cylinder motor, according fairly with present practice.

The T type of cylinder, having inlet and exhaust valves on opposite sides, demands the use of two camshafts, and offers the advantage of symmetry of the cylinders, with attending advantages. In the L type of cylinders but one camshaft is required, since the valves are on one side only, and lack of symmetry of the casting is one of the conditions to be tolerated. With valves in the head it is the custom to use but one camshaft, and in notable instances the camshaft was superimposed. Noiseless performance is more difficult of attainment when camshafts are so placed, due to lost motion to some extent; and to lack of muffling following the exposed position.

(*To be continued*)

NEW NICKEL-IRON BATTERY WITHSTANDS TESTS

EDISON, the inventor, has promised a storage battery that would revolutionize the industry so many times, each one on trial being marked by a failure that the people have begun to be skeptical of any Edison battery. However, the new type of nickel-iron battery is out and, says *The Commercial Vehicle*, for nearly two months past the Edison battery, for which electric vehicle users have been waiting so long and impatiently, has been undergoing tests in the regular daily service of one of the leading department stores and one of the largest drygoods establishments of New York City, the two largest users of commercial vehicles in the city with the possible exception of the Adams Express Company.

R. H. Macy & Co., who own and operate thirty-one electric delivery wagons and trucks, had a Lansden wagon fitted with one of the new batteries for three weeks, since which time it has changed hands, being in the service of the pioneer dry goods house, a house that to-day maintains forty-one commercial vehicles, both gasoline and electric, but which as a matter of policy declines to allow the use of its name. By all who have had anything to do with the new battery it is spoken of in the highest terms of approval. But the best presentation of its efficiency will be made by telling exactly what has been accomplished with the battery in an ordinary electric vehicle.

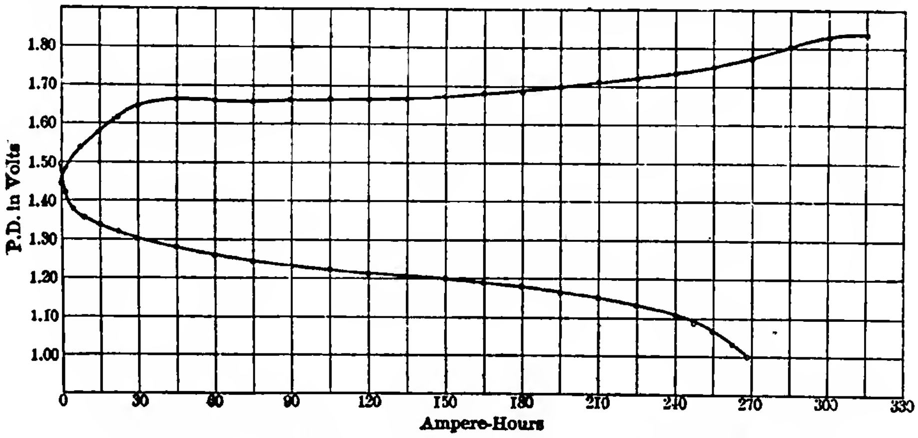
Details of the Two Sizes Made—The new battery is made in two sizes, designated A 4 and A 6. The former is of the same capacity as the earlier type E 27 Edison battery, rated at 150 ampere-hours discharge. Type A 6 has the same number and size of cells as type E 27 and is of about the same weight, but has nearly double the capacity, giving 260 ampere-hours discharge. It requires a charge of 300 ampere-hours, but the users say the loss is much more than counterbalanced by the work it does and by other points of practical excellence. The smaller size battery weighs about 700 pounds and the larger size 1,200. Size A 6 is installed in a demonstration wagon of Lansden make which has been christened the *Greyhound*, for reasons that will become obvious. At the time an investigation of the performance of this outfit was made, up to June 21, it had been running in the service of the drygoods store for nearly a month.

Upon being received it was given a special test, in which it was run three consecutive days without recharging, and made a total mileage of 93 miles. On the first day it left New York City at 8 o'clock in the morning, crossed the ferry to Jersey City and covered the Bayonne route, going all the way to Bergen Point, making approximately 100 stops for delivery of packages. It returned to the garage at 6 p. m. The same route was covered on the second day, starting at 8 a. m., making about the same number of stops, and getting back at 5 p. m. On the third day it traversed the regular Staten Island route for the store, embracing nearly all the towns on the north end of the island, which is very hilly, and making about one hundred stops. It left the store for this trip at 8.30 a. m. and got back at about 8.30 in the evening. During this entire period the battery received no "boost" and was not recharged. At the end of the test, the voltmeter reading showed 60 volts.

Unusually Severe Route Traversed—Following this initial test, the *Greyhound*, with battery A 6, was put on the Coney Island route, which is claimed to be the longest and hardest covered regularly in one day by any dry goods house in the city. It is from 63 to 67 miles long and averages 150 stops for deliveries, sometimes running up to nearly 300 deliveries.

In covering this route, the *Greyhound* leaves the store in New York City at 8 o'clock in the morning, crosses the Brooklyn Bridge, and thence runs out Fourth avenue to Sixtieth street, where deliveries begin. From there it goes to Fort Hamilton, making deliveries along the way, returns to Dyker Heights, then does part of Borough Park. From Borough Park, it delivers all the way down to Bath Beach, taking both sides of the main line, thence through Bensonhurst to Ulmer Park and on down to Coney Island. It covers Surf avenue, in Coney Island, all the way to Sea Gate, at the westerly end. Returning, it goes to Brighton Beach, then cuts over to Sheepshead Bay and starts on the homeward trip, coming back through Flatbush, where it finishes its deliveries, and re-enters Manhattan by way of the Williamsburg bridge. The wagon usually reaches the garage at 7 p. m.

If there are an unusual number of deliveries to be made the driver is accompanied by a boy to carry packages, but otherwise he is alone. It is an enormous day's work to be done week after week, but the driver likes it because he gets back from his work about three hours earlier than when horses were used. One reason why it is possible to make so many deliveries on such a long route in so short a time is because, unlike the city routes, there are no stairs to climb to upper floors of flat buildings.



Characteristic Curves on Charge and Discharge of Nickel Iron Battery

When this route was covered with horses, two teams were used every day and hampers full of packages were shipped by express to Bath Beach, about midway of the delivery route, where the wagons called for the packages and began their deliveries. Very often the wagons could not start delivering until 10 a. m.

Details of the Car with Which the Test Was Made—The *Greyhound* is a one-ton wagon of the regular Lansden type. It weighs 2,460 pounds empty, without battery, and 3,660 pounds with battery; that is, the type A 6 battery weighs 1,200 pounds. The wagon averages about 11 miles an hour actual running time.

The smaller battery, type A 4, has been in use by the same house in one of its two-year-old Lansden 1,000-pound wagons since June 1. In order to test it out, it was first tried on the Coney Island route, already described. It covered 45 miles over heavy, muddy roads, making 175 stops for deliveries, before the battery charge gave out. This showed that it was incapable of serving this route, however, so it was put on the Bayonne route, running down to Bergen Point. It has regularly served this route ever since, covering an average of 43 miles a day and making 125 stops. The voltage reading of the battery after the day's work shows that it is capable of doing 50 miles a day under the same conditions. The wagon leaves the store about 8 a. m. and gets back to the garage at 5 to 5.30 p. m. It is not given any boost during the day—in fact, the drivers are not allowed to boost the batteries in any of the cars. This small battery contains 65 cells and weighs very close to 700 pounds.

Various characteristics of the new battery are commented upon by the superintendent of the garage and others connected with the management of the store under whose direct observation the work of the delivery service comes. The most important is the uniformity of discharge capacity regardless of the age of the battery as shown by the curves and table on this page. This is the chief characteristic, perhaps, of all Edison batteries, as the dry goods house has one of the early ones (type E 27) that has been in its service for nearly five and one-half years and is to-day regularly doing 35 miles a day. Practically no other work has been done on it in that period except to recharge it with potash every six months, and of course to keep the cells filled with distilled water. This quality, it is pointed out, is of great value, as it relieves the superintendent of deliveries of the mental effort of remembering the capabilities of each battery according to the time it has been in use, so that a battery capable of doing, say, 20 miles, will not be put on a route 30 miles long and get stalled.

EDISON CELL—TYPE "A 6"

Weight, 19.5 pounds

Charged 7 Hours at 45 Amperes		Discharge at 45 Amperes
Ampere-hour input.........	315.0	Ampere-hour efficiency..85.2%
Ampere-hour output........	268.5	
Average P. D. of charge...	1.692	Volt efficiency...........71.1%
Average P. D. of Discharge.	1.202	
Watt-hour input...........	533.0	Watt-hour efficiency.....60.6%
Watt-hour output..........	322.7	

Output per pound.....16.54 Watt-hours.

Another quality is that the battery does not heat up much in charging, resulting in lessened evaporation and less frequent refilling. There is no testing with a hydrometer daily, and no use of acid, all that is required being the filling of the cells with pure water, as the potash does not evaporate. The reason for the lessened heating during the charging operation is said to be due in part to the large air space between cells.

Facts from Three Weeks' Service—During the three weeks that the Macy department store has the *Greyhound*, it was given severe tests over a number of different routes into the suburbs. For example, on April 16 it went to Coney Island, making about fifty deliveries, and on the same day, without recharging, it ran to Woodlawn and back. Then, to completely discharge the battery, it was run about 10 miles in nearby deliveries in the neighborhood of the store. The distance covered during the day was between 87 and 90 miles. The charging plug had been taken out at 8 a. m. and was not put in until 3.30 a. m. the following day.

On May 5 the wagon was sent to Morristown, N. J. Leaving the store at about 8 a. m., it covered 72 miles out and back, up hill and down, over macadamized roads, making forty-five stops, and returned to the garage by 9.30 p. m., or two hours before a team of horses would return to the stable in Newark after serving the same territory in Morristown.

On another occasion the Staten Island route was served, including Tottenville, at the extreme southerly end of the island. Owing to the hilly nature of the roads there it is asserted by the manager of the garage that 50 miles on the island is equivalent to 80 or 90 miles over level, smooth roads. Yet the wagon covered the route, making sixty stops, and returned, running strong, in five hours' less time than the same deliveries could have been made with teams of horses.

During the three weeks that Macy's had the wagon fitted with the new A 6 battery the machine was regularly put on the longest routes, serving suburban territory that is usually handled by horses or express. Besides the Tottenville route, which is 56 miles long, there was covered the trip to Richmond, also on Staten Island, 48 miles; Scarsdale, in Westchester County, north of the city, a round trip of 43 miles; Coney Island, and others, in regular rotation.

The wagon was regularly worked from 14 to 18 hours a day, according to the chief engineer of Macy's, and averaged from 56 to 57 miles a day on one charge, returning regularly still good for ten miles. It was regularly recharged at night for six to seven hours at a 40 ampere-hour rate.

Delivery experts state that the battery is easily capable of serving the longest and hardest route operated out of New York City and of surpassing the physical endurance of the driver; that is, no driver even with the aid of a boy, could drive the machine, day in and day out, over a longer route and make more deliveries than the *Greyhound* is capable of.

Those who have supervised the work of the battery are more than enthusiastic over it. They admit that the first cost is high, but to offset this, point out the low cost of mainenance

The Battery Details and Mechanical Make-Up—While the improved Edison battery has been under test for a long time in vehicles connected with the maker's laboratory, the sample batteries here discussed were put into commercial service so that the performances could be verified under the conditions of trade. Edison's new A type differs from the older Edison battery in the mechanical construction of the positive plate and in the substitution of pure nickel for the graphite formerly used. The general form has not been altered and the negative plate is still composed of nickeled steel boxes of rectangular section filled with oxide of iron. In the new positive plate, however, the active material is contained in nickeled steel tubes, about the thickness of a lead pencil and four inches in length. These are formed spirally out of strips of perforated ribbon steel, nickeled, and are reinforced by nickeled steel rings spaced 1-2 inch apart. The tubes contain alternate layers of nickel oxide and pure metallic nickel, loaded under pressure. The ends of the tubes are crimped, forming a flat at each end which is held fast to the frame of the positive plate by notched strips on the plate. The result is a very stiff plate which could be thrown across a battery room with very slight chances of even bending it. The electrolyte is composed of a 21 per cent solution of caustic soda as before. Aside from the cells, a new form of crate has been adopted with bent corners instead of dovetailed, making a very light and stiff construction.

EFFECT OF MOTORS ON LONDON STREETS

London, July 2—An anti-motorist member of Parliament has questioned the president of the Local Government Board as to the "greatly increased" cost of road maintenance in London since the advent of motor traffic. The official reply silenced the questioner and clearly shows up one of the big advantages of horseless traffic. The following figures were given:

	Cost of Maintenance and Repair	Cost of Cleansing, etc.
1901-2	£745,461	£738,195
1903-4	771,490	724,213
1905-6	820,267	757,182
1907-8	745,601	723,790

The total length of roads here referred to has increased from 2,088 miles in 1901 to 2,162 miles in 1908. The substantial decrease in both maintenance and cleansing costs since the general introduction of motor vehicles some two or three years ago is so marked as to be well worth recording, placing the automobile, as it does, within the reach of a greater number of people.

CITY OF THE STRAITS FIRST ON THE LIST

Detroit has more automobiles in proportion to its population than any other American city, with the possible exception of Los Angeles. Supremacy in this respect is a mooted question, but there is no chance for argument when the natural advantages of the two cities are considered. Detroit has broad, well-shaded, well-paved streets that offer every inducement to motorists. Traffic regulations are liberal because of a keen appreciation of what the automobile means to the city. The parks and boulevards are always open to owners of machines, and if there ever comes a time when the motorist tires of riding around town he can drive out into the country in any direction and for a sum so small it would make a New Yorker gasp with astonishment enjoy a chicken dinner, feast on Detroit River whitefish, famous wherever epicures are found, or gorge himself on frog saddles such as only Detroit produces, and which have been eulogized at length by Eastern writers on more than one occasion.

ON DRIVING A CAR AT NIGHT

By D. R. Hobart

UNLESS one has had considerable experience in driving by night, and no matter how well he may know the road by daylight, he is often utterly at a loss to recognize familiar objects and will even pass the place to which he desires to go without being aware of it, when traveling over the same road after dark. Objects by the roadside have an unnatural appearance and seem out of proportion; what appears as a dark patch in the road may be either a pool of water or a depression, and light colored objects by the side of the road may even be taken for the road itself. The road, too, apparently disappears a short distance ahead and the autoist sets the brakes, only to find himself deceived. Due to the combination of deep shadows and strong lights with the general gloom of the night, all sorts of objects created in the imagination seem to spring up, causing doubt and anxiety. For comfortable night-driving as well as for the safety of the car and its passengers, powerful lamps are an absolute necessity.

Practice Essential to Proper Night-Driving—Recognition of familiar objects and accurate judgment of road conditions can only be acquired by practice. It is not necessary, to accustom one's-self, to drive night after night for periods of from six to eight hours on a stretch, as such long periods give rise to a high-strung and nervous state on the part of the driver. The first drive should not take over an hour and the autoist should be accompanied by a companion familiar with night-driving and the roads that are to be traversed. This companion should point out deceptive appearances and explain their true character, and in general act as an adviser. Unnecessary talking should be avoided by both as tending to distract attention from the work in hand. Subsequent drives can be of greater duration and on some of these the companion should not give instruction allowing the driver to take care of himself but acting when an emergency arises. As a general rule, no matter how experienced an autoist is in night-driving, there should be someone in the seat alongside to watch the road and the majority of drivers are only too glad to have such assistance.

Effect of Street Lights—Running in city streets or on lighted roads is of course much easier than running on dark roads, but in such cases the eyes are constantly accommodating themselves to the changes in light as the car approaches and passes a street lamp. With the powerful arc lights in use in many cities, the view will be obscured for a short time as the car passes out of the circle thrown by the light and a feeling of blindness will result, soon passing off, however, as the eyes adjust themselves to the change in quality of the light. It is due to this effect on the eyes that a number of the minor accidents occur at corners, not only to autos but to horsed-vehicles and foot-passengers. When emerging from light into what seems total darkness, as when leaving the last light of a city and going along the unlighted road, an involuntary sensation of being lost is experienced and even with powerful headlights the feeling of blindness occurs for a short time.

Goggles Not to Be Used Because of Reflections—Except when absolutely necessary, goggles should not be worn nor should the wind-shield be raised when driving at night, as the reflections from street-lamps or other sources of light on the glass surfaces of the goggles and shield appear as direct lights and obscure objects on the road, with unhappy results. A hint in this direction can be taken from the locomotive engineer who drives at night with the cab windows down to prevent any possibility of reflection, the only light in the cab, the gauge lamp, being placed directly in front of the gauge where no angular reflection is possible. Objects outside of the area illuminated by the lamps are almost invisible, so that care should be taken in making a turn or when passing a road-crossing. It would be well to have a movable searchlight fitted and this should be played on road crossings in both directions as the car approaches them, and on the road into which the car is to turn in order to illuminate objects not shown up by the headlights. Otherwise the searchlight can assist the headlights in illuminating a greater vertical area and give warning of dangerous objects at a distance.

Speed and Courtesy—Only a very reckless driver or one under the influence of liquor would drive a car at extreme speed at night. Not only would he endanger the other occupants of the car in so doing, but all other road users, especially those whose lights are not as powerful as his own. To be on the safe side and to accord fair treatment to all others on the road, a car should never be driven at such a speed as will necessitate the use of goggles or a wind-shield. Courtesy on the road does not disappear with the sun and because one has a powerful car and large lamps he is not justified in causing annoyance or injury to less fortunate users of the road. To the credit of the majority of autoists, most of the violations of courtesy are on the part of horse-drivers or other road users, a striking example being the moving-van driver who persistently occupies the crown of the road, thus preventing others from passing him, or who picks out the narrowest part of the highway as a suitable place to breathe his horses. The cattle driver with his herd occupying the entire width of the road and without any lights at all is another offender who constitutes an element of danger, in addition. Both of these must be watched for on summer nights and in localities where market wagons or herds are driven from one place to another by night, moderate speed is all that can be indulged in with safety. As in the daytime, the same courtesy should be extended to all other road users at night and it should be remembered that in case of accident, it will go harder with the autoist at night than if the trouble occurred by daylight.

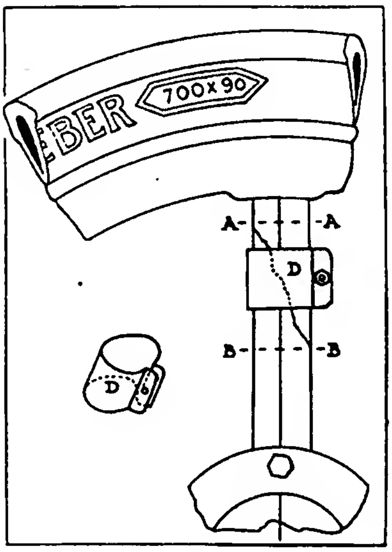
The Lights of Traffic—Traffic on our roads is, unfortunately, noticeable in the main by the absence of lights of any description. Though nearly all States specify that all vehicles shall carry lights, the laws are honored more in the breach than in the observance. Most of the mishaps on the road at night are rear-end collisions, or as a result of endeavoring to avoid such collisions. When horse traffic carries any lights, they consist of either a pair of oil dash-lamps or a lantern slung under the running-gear, and none of these lights can be seen for any considerable distance. So whenever a faint light is seen ahead, the autoist should drive cautiously until the nature of the object bearing the light and its direction of travel if it has any is ascertained. In the majority of cases, the object will be a vehicle, although road repairs are often marked by a white lantern instead of a red one. As the autoist becomes experienced in driving at night, he will soon be able to distinguish the characteristics of the different forms of traffic; a large dark blotch signifying a wagon, small whitish spots in the near distance the faces of pedestrians, and a dancing "wil-o-the-wisp" effect a cyclist, the intermittent flashes being due to the reflection of the headlight on the plated parts of the machine. It is of course easy to know the direction of travel of a vehicle when red lights are seen on it as it is then moving in the same direction as the autoist. The absence of any light does not necessarily indicate the fact that no vehicle is present and this should be borne well in mind at all times.

Lamp Equipment and Its Proper Positioning—For properly illuminating the road and objects surrounding it, the lamp equipment should consist of one or two headlights, a pair of side-lamps, a tail-lamp and a swivelling searchlight, although the latter is not absolutely necessary in some cases. The headlights should be carried low down and well forward, not only to better illuminate the road but to cease to dazzle other road users. Each lamp should be set on the forks or bracket so that its principal rays will be thrown horizontally, and should be pointed directly ahead, especially if only one headlight is fitted, as the autoist unconsciously follows the beam of light in driving. The searchlight is usually mounted on a swiveling bracket on the dash where it can readily be moved by the hand. Side lamps rest in brackets on each side of the dash and act as auxiliaries to the headlights in illuminating roadside objects outside of the beams thrown by the headlights. In cities where the use of search- or headlights is forbidden, the side lamps must be depended on alone, and when any driving is done in cities fairly powerful lamps should be used. Side lamps are valuable in case of tire or other trouble, as they can be readily removed from the brackets to light up the work. The tail lamp should be placed out of the path of the exhaust so that the light will not be mysteriously extinguished and the fact called to the autoist's attention by the police, as is usually the case. An electric tail-lamp with a small bulb wired in series therewith so that the extinguishing of this bulb will indicate that the tail lamp is also extinguished is far better than the use of an oil light.

Benefits Derived from Driving by Night—When not indulged in to too great an extent, driving by night is beneficial in a number of ways. After the day's work it clears the mind and fills the lungs with fresh air. The rapid passage of the car gives rise to a sense of buoyancy and the reaction therefrom causes a feeling of drowsiness which makes the autoist sleep like the proverbial top. Especially is this the case with nervous persons or those whose occupation keeps them indoors for the greater part of the day. Driving at night should be indulged in in the warmer months of the year, as in the winter, driving in an open car is far from pleasant and may subject the riders to neuralgia or rheumatism. Driving in a closed car prevents the thorough enjoyment of the air currents, and while the mind may be cleared, it is, in the writer's estimation, but little superior to riding in a train or closed street-car.

LITTLE THINGS WORTH REMEMBERING BY THE AMATEUR

Temporary Repair to a Broken Spoke—Haste or carelessness in driving usually results in marring the paintwork, tearing the tires or damaging the fender, as when shaving a corner or making too short a turn and colliding with other objects in so doing. Sometimes more than paint and fenders are affected, a spoke in one of the wheels being broken or split so that safe progress is impossible. Where the autoist is unprovided with detachable wheels, as is usually the case, recourse must be had to some temporary binding or splint so that a repair—or wheelwright—shop can be reached. Such a break and a splint for keeping the broken ends in their proper relation to each other is shown in the sketch. A brass water connection collar, D, was bent into the approximate shape of the spoke by hammering it around the corresponding portion of another spoke, and after the broken ends were joined, the collar was put in place and the nut and screw set up. The collar held for some miles with careful driving, and in the opinion of the autoist who applied it, would have continued to keep the parts together for some time afterward. Where no such connection is at hand, steel wire wrapped around between AA and BB will answer for a very limited time, and very careful driving is necessary at that.



Clamp to Hold Broken Spoke

Recipes for Cleaning Leather Gloves—Ordinarily, soap and water are unsuitable for cleaning leather gloves more than once, as the scrubbing necessary destroys the dressing of the leather and causes a fibrous and untidy appearance which results in the deterioration of the article. An excellent solution which will clean with practically no deterioration consists of one drachm of sodium carbonate in one quart of milk, keeping these proportions only, however, as it is not often necessary to use such a quantity of mixture at any one time. The glove to be cleaned is put on the hand or on a wooden form and the solution applied with a piece of flannel, cotton or a wool brush such as comes with patent shoe dressings. After the stains or spots have been removed, the glove should be rubbed dry with a clean, soft cloth. Another method of cleaning employs Castile soap and milk, a cloth being dipped in the milk, rubbed on the soap, and the glove cleaned as before. Coarse soaps or those having considerable alkali should not be used on leather on account of the destructive action of the alkali and the effects of scrubbing as mentioned above. Under no circumstances should the cake of soap be rubbed on the glove, and it should be borne in mind that no dirty cloths nor rags whatever are permissible.

Cleaning Rubber Mats—Cars are frequently seen on which the brass and nickel plated parts are brilliantly polished but the rubber floor mats are dingy and greatly detract from the general appearance of the car in consequence. An excellent method of keeping the mats bright is to give them an occasional coat of white or gray paint. Frequent scrubbing with soap and a brush is another means often employed, but while this cleans the mats the worn places look patchy, which is not the case when paint is used. White shoe dressing or pipeclay gives a smart appearance, but in wet weather the dressing gets pasty and is trodden into the floor-boards and cracks, where it is difficult to remove. If the mats can be cleaned daily, scrubbing with soap will answer unless they are badly worn.

A Deadener for Noisy Gears—When metal gears are run unhoused, the ringing noise which they make is quite noticeable, and if the gears are set too closely the noise becomes objectionable. As it is often inconvenient to stop and reset the gears, the noise can be deadened by rubbing the teeth and the grooves between the teeth with beeswax which has previously been warmed or well kneaded with the fingers. In a short time after applying the wax the noise will cease. The wax coating will remain on the gears for a considerable period of time, but the gears should be set properly in preference to applying another coating. Common bar soap, which contains a large percentage of wax, can also be used as a deadener.

Roadside Puncture Detecting Wrinkle—Small punctures in inner tubes are usually located by partially inflating the tubes and either immersing them in water or smearing them with soap lather, the puncture being indicated in either case by bubbles. On the road, the autoist is sometimes unable to procure a vessel suitable for testing the tube, but the tube can be laid in the dust and the puncture will be indicated by the blowing away of the dust at the point where the air leaks from the tube. This method requires no preparation, and is as sure as either the lather or water immersion methods, besides taking considerably less time.

Letters Interesting and Instructive

HAS NUMEROUS TROUBLES

Editor THE AUTOMOBILE:

[1,940]—Will you please inform me through "Letters Interesting and Instructive" on the following points:

(1) Why does my 1903 opposed engine, 16-20 horsepower, under the body, on car which is chain driven, use up four gallons of water on a 16-mile run? Pipes do not leak more than two or thee drops per minute.

(2) Why does this same car, although the engine runs smoothly, seem to have a jerk or surging motion at irregular intervals? This begins as soon as the car gets under way and occurs at intervals of from fifty feet to a hundred yards and continues throughout the run, although it gets no worse, it gets no better. Brake bands and transmission bands do not drag, engine is lined up, and all bearings are oiled before starting. Chain also is not tight.

(3) Why does this motor, which is equipped with a popular carbureter, not give more power when the throttle is wide open than it does when almost closed? On the other hand, it is very sensitive to a slight spark advancement, with the throttle partly open.

(4) Why does this motor after being run three miles under normal conditions, continue to run after the plug is pulled out. This is apparently on one cylinder and will continue for a long time, after which it will reverse a couple of times before stopping. This condition prevailed both before and after the cylinder and piston had been scraped free from carbon. It also occurs before the water gets to the boiling point as well as after. Water circulation is by gear pump.

(5) What causes this car to make a tapping sound when speeded up with spark not too far advanced? Also, while going down grade and coasting with the clutch out the same noise is heard. If I take the clutch out while running along on a level road at a 15-mile clip, it is heard and also when the engine is shut down after running at good speed. SUBSCRIBER.

South Braintree, Mass.

(1) You say two or three drops as if you are not sure. In that case, might not the right figure be twice as much? It would seem as if this small leak accounts for the loss of water. Since hot water flows more freely than cold, might not your five or six drops per minute (cold) become even twice that when the water gets up to 190 degrees? Of course, there may be the possibility that you have a trapped passage in one or both of the cylinders in which steam forms, thus preventing the circulation of water, with the result that more steam forms and the water boils away very rapidly. This latter fault can readily be detected in the overheating of the engine.

(2) If your car were shaft-driven, a misplacement of one of the universal joints would account for the surging. As it is, a single stretched link in the chain might cause the effect you have noticed, or even an irregularity in one of the sprockets. The fact that it continues throughout a day's run without increasing or diminishing would seem to account for the trouble as located in either chain or sprockets.

(3) Your carbureter and power trouble sounds very much as if the spray nozzle had been raised too high, resulting in starving the engine at wide-open throttle and high speeds, while at low speeds and partly open throttle an excellent mixture is obtained and the engine runs very well and delivers lots of power. This is explained in full, with a drawing to illustrate the point, in the June 17 issue of THE AUTOMOBILE, in answer to letter No. 1919, which you would do well to refer to.

(4) In this case, you have one cylinder in which there is a projection. This collects the heat and ultimately becomes red hot. It then acts as an igniter and fires the charge, so when the regular source of ignition is cut off it continues to fire until the fuel is used up or until it loses its heat. As a very small projection will often cause this you will have to look closely to find it.

(5) The tapping sound might be caused by so many things that any suggestion we might make based on the facts that you have sent in would be in the nature of a guess. Being right on the ground and with the machine before you, you ought to be able to make a better guess than we could.

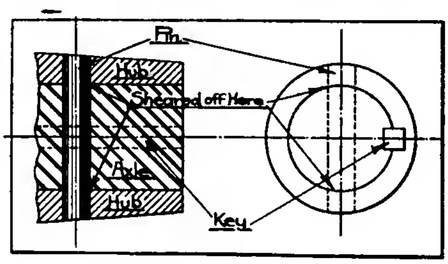
STAGGERING REAR WHEEL

Editor THE AUTOMOBILE:

[1,941]—Can you advise me through "Letters Interesting and Instructive" what would cause this trouble: The right-hand rear wheel "staggers" over rough pavement and very frequently I find the hub pin broken into three pieces. The key also wears very rapidly. The car is a Reo runabout. All other wheels are tight and as good as new. A. A.

Cleveland, O.

Your trouble, very apparently, is that the hub is loose on the axle, allowing it to move slightly in one direction and then in the other, when running over rough pavement. This alternate back and forth movement shears off the pin and makes the key loose. The remedy is to have the hub bored out large enough to allow of pressing a bushing into it. Then the latter should be rebored to axle size, allowing *not over* two-thousandths of an inch for clearance. This will be tight enough so that a few light blows with a hammer will be required to put it into place. Then a new key should be made which is a driving fit. As to the pin, have a new one made of a superior material, say, nickel steel. Then be sure that this is a tight fit also, and drive it into place yourself. If everything is tight, there can be no "wobble" or "stagger," which results in the sheared pins.



Showing How Hub Pins Break

ABOUT GARAGE FLOORS

Editor THE AUTOMOBILE:

[1,942]—I wish to garage a car in a stable which has a plank flooring. Owing to the fact that there is a cellar beneath the floor, it is not deemed advisable to lay concrete or any similar material thereon. Can you suggest any floor covering? H. R. FOLLETT.

Norwich, Conn.

The mere fact of there being a cellar below should not deter you from using concrete, which will make the best floor in the long run. Contrary to the usual idea, this need not be made very thick, an inch of neat or nearly neat cement being sufficient. This much cement will not be very heavy, so you need have no fear of the wooden floor standing up under the load.

Metal could be used, but has several very apparent disadvantages; it is heavy, expensive, noisy and hard to handle, which means a lot of hard work if you plan to cover the floor yourself. If metal was objectionable, and you did not mind adding a few inches to the thickness of the floor, brick laid on the side in cement could be laid cheaply and would make an excellent floor. Should you object to this thickness (2-inch), tile could be used in a similar manner, although this has the disadvantage that anything heavy dropped on it will break a tile or a couple of tiles. This means a nasty job replacing them.

There is a floor covering which is an asbestos paste, and can be put on in any desired thickness, one-half inch being recommended by the makers. This is sold under the trade name of Crown Sanitary Flooring by Robert S. Keasbey Company, 102 N. Moore street, New York City. It has the advantage of being easily and quickly applied, is water, oil and fire proof, can be had in any desired color, is seamless and practically indestructible. Probably this would answer your purpose.

NOISY TIMING GEARS

Editor THE AUTOMOBILE:

[1,943]—Perhaps some of your readers who have had experience with Ford runabouts of the 1908 type, or years previous, can suggest some way for lessening the noise of the timing gears. There may be some way of enclosing them, even though the arrangement would not be oil-tight, which would do away with the ringing noise. J. R. ZECKWER.

Philadelphia.

Just as a suggestion you might try the use of a fiber or rawhide gear in place of one of the metal gears now on the engine. This will doubtless eliminate some of the noise. This, too, would be an advantage in case you tried to enclose the gears with some form of sheet metal cover, as in the use of rawhide or fiber oil cannot be used, so the problem of covering the gears would be simplified. Readers who have been bothered in this same way are invited to write in and tell how they avoided the noise.

SARATOGA TO NORTH CREEK

Editor THE AUTOMOBILE:

[1,944]—Will you kindly publish in your columns a suitable route from Saratoga to North Creek. G. J. R.
Albany, N. Y.

Complete running directions from Saratoga to North Creek have not yet been compiled, but a fair idea of the route can be had by reference to the New York State volume of the 1909 edition of the "Official Automobile Blue Book" (page 3).

The route from Saratoga to Lake George, which was traveled and written new by the Blue Book Car in the Fall of 1908, will be found complete on pages 431-433.

As one leaves Lake George for the Adirondacks the road to North Creek is noted on the left. This will probably be traveled and written new for the 1910 Blue Book.

THERMAL EFFICIENCY

Editor THE AUTOMOBILE:

[1,945]—In your esteemed paper dated June 10 appeared an article entitled "Thermal and Combustion Efficiency of a Motor," by Prof. W. Watson.

In the paragraph headed "High Efficiency Very Noticeable" are given some figures on which I would like to have some enlightenment, as my own work gives me the following results:

HEMISPHERICAL COMBUSTION CHAMBER

	A	B	C
V	11.23	12.39	14.20
A	19.25	20.50	22.45
Ratio	1.72	1.65	1.58

These results I have reduced to cubic inches for convenience instead of using centimeters as Prof. Watson does. Now these differ very widely from his results, which were:

Ratio	.99	.94	.88

Will you kindly try to explain this wide difference? A. P. PLANT.
Los Angeles, Cal.

Professor Watson states that his is "a rough estimate of the surface area," so that it is possible that the area was not calculated as carefully as in your case. Even this would not account for the large discrepancy, so we are forced to conclude that your hemispherical combustion chamber is not a true hemisphere, but contains valve pockets and other extensions which increase the area relative to the volume. That this has some basis in fact you will notice from a review of the table in question. In the first part of his table, Watson gives the measurements of the engines under test, and for these finds ratios as follows:

A	B	C
2.01	1.86	1.69

It is with these that the hemispherical chamber is compared, and in his comparison, Watson says: "That this ratio could be very materially reduced is shown by the numbers given for a combustion chamber having no valve pockets, a hemispherical top, and a flat-topped piston. In such an engine the ratio of surface to volume would be only *one-half* what it is actually."

To repeat, your figures, coming midway between the figures for an actual engine and a theoretically perfect hemispherical chamber, lead us to think that you have not a true hemisphere, but incline more to the enlarged shape, which is more usual. All this, of course, providing that your arithmetic is correct.

Another idea is this: the area of the surface of a cylinder is greater than that of a hemisphere of the same diameter and equal volume. So any tendency toward a cylinder and away from the hemisphere adds to the surface area and consequently to the ratio. So it is barely possible that you have an engine of very low compression as compared with those used by Professor Watson. Lower compression means, of course, greater volume in the compression space, but this in turn means a greater departure from the spherical shape, with accompanying increase in the area. The last, in turn, raises the ratio. So, it may be that the only difference is that you have a motor with low compression.

It might not be thought that the compression pressure would influence the amount of area of the combustion chamber, and with it the ratio of volume to area, in this manner, but a few moments' thought will convince the most skeptical that this actually is the case. The above explanation, then, is the true one, and Plant will have to increase compression to improve the ratio.

ROTARY MOTORS

Editor THE AUTOMOBILE:

[1,946]—Can you inform me of any rotary or turbine motor such as is or can be used for aeroplanes or balloons, and if so, the names and addresses of the manufacturing companies?

What style of motors are used for the above purposes and what lengths of propeller blades are used? L. WOLFLEY.
Los Angeles, Cal.

As yet there have been no gas turbines perfected to the point of use in aerial craft. The engines used come in one of two classes, either they are of the V type or of the rotary type. If you will consult the back numbers of THE AUTOMOBILE you will find these treated very extensively. Thus in the January 14 issue the two types of engines are discusssed and compared, while the following rotary engines are described in detail: Eight-cylinder Farcot, seven-cylinder Clement-Bayard, seven-cylinder Gnome, and others. In the February 25 issue there is an article on a revolving type of two-cycle motor, which has but four rotating cylinders.

Then in the April 8 issue will be found a complete description of the work being done in England in the aeronautical line. Following this, the issue of April 15 gives the details of the seven-cylinder revolving Gnome engine, a French production.

Nearly all of these articles also treat of the sizes of propellers used, but as a general statement the size varies from 5 feet to 7 feet in diameter. The lower figure is seldom if ever surpassed, while the upper limit is usually not reached, either. The usual size of propeller blades, considering the difference in the various uses, is not far from the average of the sizes given above, namely, 6 feet. This is the exact size used by Curtiss on his aeroplane, described in THE AUTOMOBILE of July 1.

DIFFERENTIAL AGAIN

Editor THE AUTOMOBILE:

[1,947]—I notice your answer to No. 1,915. He asks about the effect of puting the slip joint of the propeller shaft on a quarter turn wrong. I gather that you assume the slip joint to be on the final driven member, in which case your answer would be correct; but I think from the surging he describes and from the very common custom of having the slip joint on the intermediate shaft that he has misplaced the slip joint on this shaft. The driving and the final shafts should be in parallel positions so the angles with the intermediate shaft will be the same at each end.

But there is a rather more necessary requirement than this. And single joint drives cannot get rid of it. This is the requirement that the forks at the opposite ends of the intermediate shaft, commonly called the propeller shaft, should lie in the same plane. If they do not there is uneven driving and the surging effect he mentions would likely follow.

This is readily seen if we consider the first figure you published in the article. It will be easier if we assume the distances between the two parallel shafts to be much greater so as to increase the angularity of the intermediate B. The fork ends of A describe a circle about the axis of A and their motion, being steadied by the flywheel, is of a steady, angular velocity. The fork ends of B describe a circle of same size about the axis of B but with relation to A this is an ellipse. In a line at right angles to a plane through both shafts the two circles cross each other and at this point we find the long axis of the ellipse. Certain it is that when the fork ends of B are at this point they are moving as fast as the fork arms of A. But when they are in the plane of the two shafts, they are closer to the axis of A than at other times and are moving relatively slower. If the short axis of the ellipse is but half the length of the major axis, then at this point (the position shown in the figure) the fork ends of B will be moving but half as fast as the fork ends of A. Thus it will be seen that the speed of the shaft B at this point of a rotation is a matter of the angle between the shafts and is always slower than that of the shaft A. A quarter of a turn later and the fork ends of B are in a line where the connecting cross is squarely across the axis, and the ends of all four of its arms are moving at the same speed. At this point the shaft B must be moving with the same angular velocity as the shaft A. Therefore we find the shaft B accelerating for a quarter of a turn, then retarding for a quarter turn.

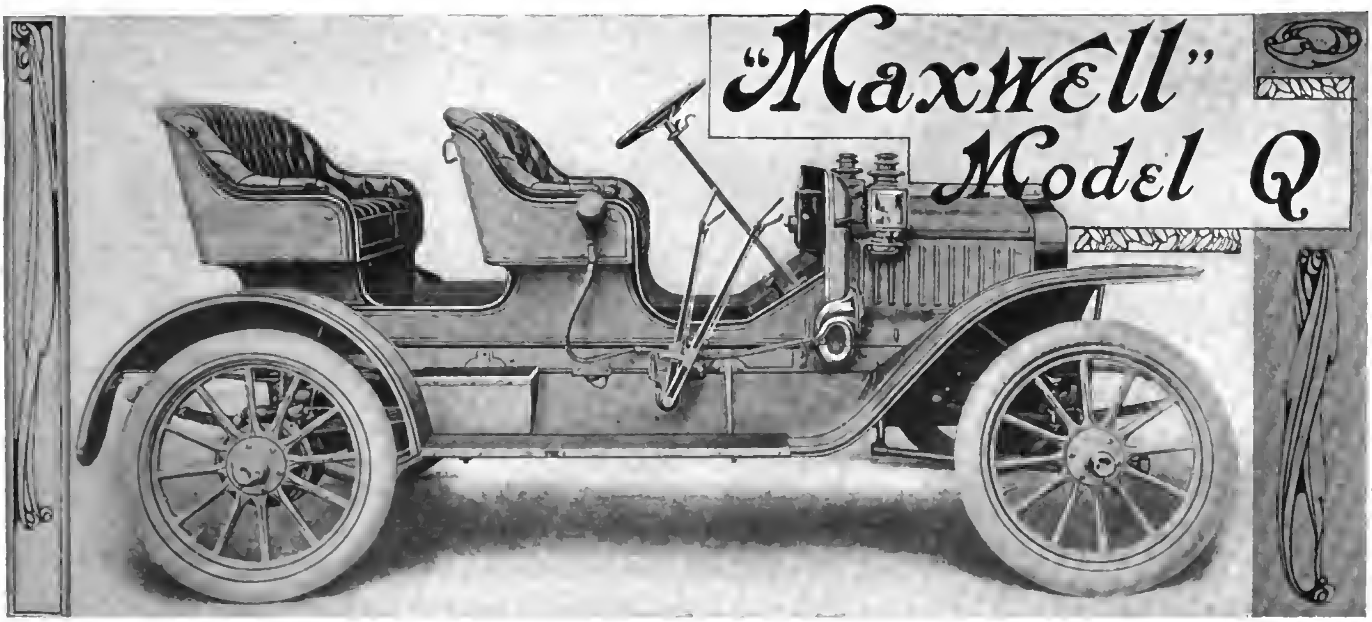
Now it should be apparent that the lower joint of B acts as a driver and has the same effect on the shaft C. That is if the angles are the same, as you correctly state. It should also be apparent that we can make the lower joint retard C while the upper joint is accelerating B. If we do this we get C rotated at the speed of A and the only irregularity of speed is found in the shaft B. This is very light and can vary its angular velocity quickly and without surging or grinding anything.

But if B accelerates C while being accelerated by A we get a doubled irregularity in C. This is decidedly bad. Twice in a revolution the engine is trying to force the wheels forward and twice it is trying to retard them. The flywheel is heavy and not easily stopped and started. The body of a heavy auto is still harder to move. The engine probably gets the effect most. It is a wonder that the gears and shafts will stand it. I have no doubt that many cases of defective gimbal joints and broken gears are due to this irregularity. And that the variation in engine speed can effect the mixture and firing is not too great to believe. The variation in motion becomes very perceptible if the angles are great. Yet many makers seem to ignore this matter as if it did not amount to much. Joint makers, who ought to know better, send out propeller shafts with the joints fitted wrong and no means for turning them right. Multiple drills are to be seen with this wrong arrangement although how drills can stand up at the fast speed if they are running at full speed when going slow I do not know. This is surely a case of going "steady by jerks."

With a single joint there is no remedy except to use a long shaft and so keep the angle slight as possible. The engine shaft should be as near in line with the propeller shaft as possible when under load.

Reading, Pa. CHARLES E. DURYEA.

As all of the matter above, or at least most of it, has been covered before, no comment is necessary. To those who find it difficult to follow the above, the figure will be found on page 987 of the June 17 issue.



WITH the gradual reduction in the price of small automobiles which came in response to the popular demand, has come an increase in the standard of material, construction and external appearance of these cars. The result is that a prospective buyer receives very much for his money. With this continuous "upward revision" of quality, accompanied by downward revision of prices, the buying public has begun to scan with care the details of each and every new model announced. So it is with the feeling of offering something out of the ordinary that the details of the new Maxwell model are made public.

This is a four-cylinder car, rated at 22 horsepower, equipped with runabout body, and in its mechanical features including all of the pronouncedly Maxwell ideas, such as three-point suspension, thermo-syphon cooling and unit engine, clutch, and transmission construction. In fact, the new car, called Model Q, follows closely after the larger and more powerful Model DA.

A special feature of this new runabout is that it is equipped with a sliding-gear transmission giving three speeds forward and one reverse. This type of transmission, while used almost exclusively on large cars, has been considered heretofore too expensive to put on an automobile selling for less than $1,000. Heretofore runabouts selling at approximately this price have been fitted with planetary transmissions.

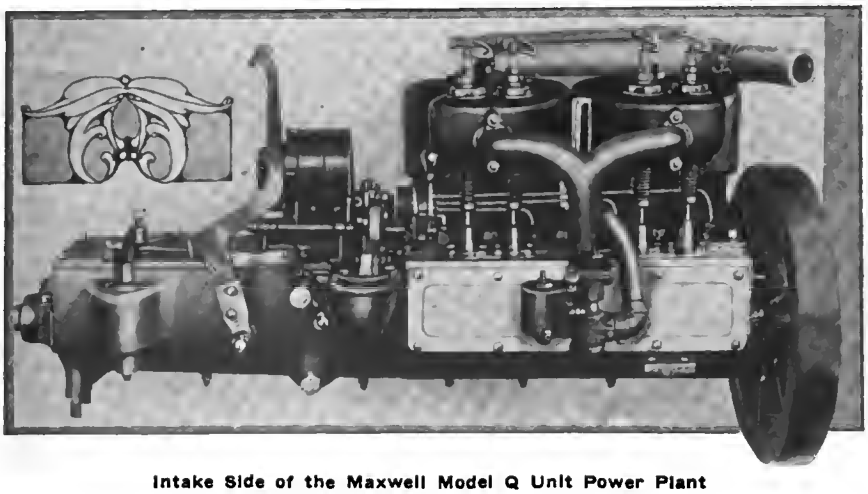
This new Maxwell Model Q will be equipped with a magneto, a set of dry cells also being provided for emergency use. The new car is put out in three styles of body, namely, the standard runabout type, having individual front seats with tool and carrying box in rear; with a rear seat for one; or with a rear seat for two. It is probable that this new model will be ready for delivery around the first of August.

What the New Motor Shows—The engine is of the four-cylinder vertical type, of 3¾-inch bore and 4-inch stroke. The cylinders are cast in pairs, the motor developing 22 actual horsepower at a normal speed of 900 R. P. M. The water jackets are cast integral with the cylinders. The valves, located on opposite sides, are interchangeable and exceptionally large. Both inlet and exhaust valves are mechanically operated. The tappet rods are of special steel, hardened and ground. The guides are of phosphor bronze. The cams are hardened and ground, and enclosed within the crank case, being thus fully protected and lubricated by splash. Three large bearings are provided for the camshafts, the shaft itself being hardened and ground. The crankshaft is of a special steel drop forging and finished by grinding. The connecting rods are of steel drop forgings, the bearings are a special grade of compressed babbitt. Throughout the entire motor simplicity and strength are the dominant features. The means of access to the connecting rods is provided on each side of the crankcase by plates which are quickly removable, thus exposing the rods for inspection or adjustment.

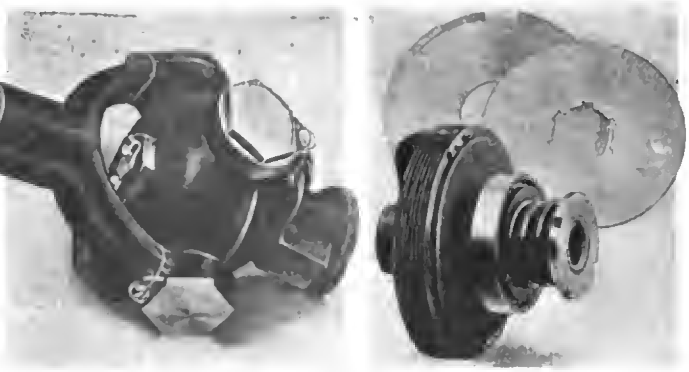
The lubricating oil is carried in a tank located under the hood; from this it is forced through a single sight feed located on the dash, whence the oil is distributed to each cylinder and to the clutch compartment. A nice feature in connection with this oiling system is a glass gauge which shows through at the dash so that the operator can at all times see the amount of oil contained in his oil tank. In connection with the lubrication of this new model is a positive oiling device for each cylinder. An oil ring is fitted at the bottom of each. This ring is constantly supplied with oil by the mechanical oiler. Into this ring the end of the piston dips at each stroke, carrying with it enough oil to lubricate freely the cylinder. This device prevents flooding of the cylinders with oil and eliminates the tendency to carbonize. This particular feature is similar to that used on the larger and more expensive cars manufactured by this company.

Natural Cooling System Utilized—The thermo-syphon cooling system which has always been a feature of these cars has been retained in practically the same form as that used on the 30 horsepower, four-cylinder model.

The carbureter is of the constant-level



Intake Side of the Maxwell Model Q Unit Power Plant



Universal Joint and Disc Clutch Used on Maxwell Car

float-feed type. The needle valve adjustment regulates the amount of gasoline, the air being controlled by a simple adjustment at the top of the carbureter.

With the simplicity and compactness of the multiple disc clutch, together with its freedom from the usual run of clutch troubles, this form has been growing in popularity steadily. It is not surprising then to find this new model fitted with an all-metal multiple disc clutch. It consists of 15 saw steel discs, each disc being concaved about 1-32 of an inch, a construction which causes the clutch to engage very gradually, without undue slipping.

Suspension from three points, allowing as it does freedom for slight twisting, is used, allowing the frame of the car to be warped or twisted by the road inequalities without injuring the vital parts of the mechanism. By using the unit construction it is possible to enclose the clutch in an oil-tight compartment, the steel disks running continually in a bath of oil. This not only eliminates wear, but permits of the slipping of the clutch without injury to the plates. The thrust from the clutch spring is taken up by a large ball thrust bearing.

Transmission Is Included in the Unit—Not only are the engine and clutch included in this unit construction, but to make it complete the transmission also is made an integral part. This transmission is of the sliding-gear type giving three speeds forward and one reverse, direct drive being on third speed. Roller bearings of the latest improved type are used throughout. Gears are drop forged from special steel carefully cut and hardened. A feature of this transmission is the positive gear lock which prevents the shifting of gears when the clutch is engaged. This safety device precludes the possibility of gear stripping, as it is impossible to change from one speed to another without first releasing the clutch.

The drive is by a propeller shaft fitted with two self-oiling universal joints. The rear axle is of the bevel gear type and the gears are drop forgings made from special steel, carefully cut and hardened. Both the main drive gear and the drive pinion are exceptionally large. The drive pinion bearing consists of two roller bearings of the latest improved type. The models, which have been driven thousands of miles, have failed to show any perceptible wear on these bearings. These bearings are lubricated by a large self-feeding grease cup. The second feature in connection with this rear axle is a special thrust roller hardened and ground and fitted against the main bevel gear. This device holds the main drive gear firmly against the drive pinion.

The frame is of pressed steel and hot-riveted throughout. The springs are exceptionally long, the front springs being 32 by 1¾, and the rear springs being 36 by 1¾. Strut rods are placed between the rear axle and the frame so as to take the driving effort off the rear springs. The wheels are of the artillery pattern and of selected second growth hickory. The tires are 30 by 3½, standard clincher, wheelbase 93 inches; tread 56 inches.

Two sets of brakes of the internal expanding and external contracting type are mounted on the rear hubs. The internal brake shoes are of cast iron expanding on a steel drum. The external shoes are lined with a special asbestos lining and contract on the same steel drum. The brake dimensions are 1½ inches wide by 9 inches in diameter.

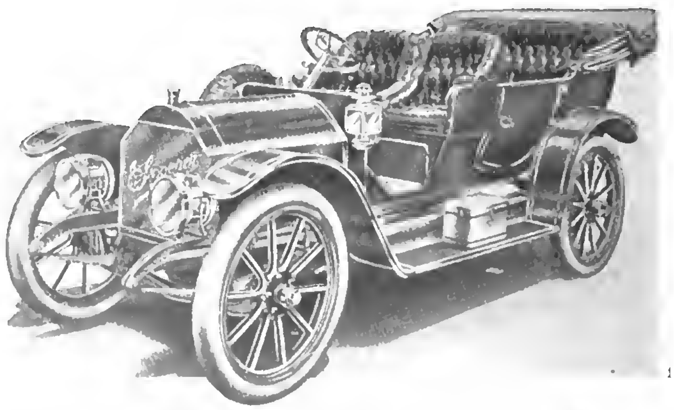
A single lever controls both the clutch and the external brake. The emergency brake also automatically releases the clutch. The spark and throttle are located on opposite sides and immediately under the steering wheel.

Metal Underpan Protects Vital Parts Efficiently—Thorough protection to the engine and transmission from mud and dust is afforded by a pan extending from the radiator to the rear end of the transmission. Metal extensions are also provided from the frame to the running board and from the frame to the fenders, so that the car can be driven through deep mud without splashing the body or the passengers. It is not generally conceded that this full underneath protection is as needful for the comfort of the passengers as for the working parts.

The body is made of sheet steel with moldings. This new model will be supplied with three styles of body: Runabout, rear seat for one, and rear seat for two. Upholstery is of high-grade leather and the best quality of curled hair. All cars will come ironed for top. The price of this new Maxwell model will be $850 for the standard runabout, $875 with rear seat for one, and $900 with rear seat for two.

PARTICULARS OF THE SPOERER FOR 1910

BALTIMORE, July 12—The new Spoerer 1910 demonstrating car, manufactured in this city by the Carl Spoerer's Sons Company, has proved substantial. Already it has been taken over all kinds of roads, up mountain sides and through stretches of mud, sand, clay, etc., for thousands of miles and no repairs have been necessary. The motor is four-cylinder vertical, rated at 30 horsepower. The cylinders are cast in pairs and are 4 7-8 diameter and 5 1-2 stroke. This is an increase over the size of the cylinders of last year, which were 4 1-2 by 5. The clutch is cone with leather face. The transmission is selectively operated and of the sliding-gear type. It has three speeds forward and reverse and is equipped with Hess-Bright bearings. The front axle is I-beam section, low drop, with Timken roller bearings, while the rear axle has a pressed steel housing, is clutch driven and of the floating type. The frame is of pressed steel of ample section. The powerful brakes are internal and external on each rear wheel. There are two separate systems of ignition, both battery and magneto. The lubrication is positive gear driven and the oil goes direct to bearings. The tires are 36 x 4. Goodrich q. d. rims. The springs are semi-elliptic front and full elliptic rear. Steering column, worm and sector, with mahogany wheel. The side levers are of manganese bronze I-beam section, while the radiator is of the honeycomb type, Mercedes pattern. The cars are made with limousine and landaulet bodies as well as touring car and runabout types. The wheelbase for the five-passenger car is 117 and for seven-passenger vehicles 124 inches. The car has a gasoline capacity of 18 gallons with pressure feed. The equipment includes side and tail lamps, horn and tool kit, together with the foot rail, robe rail and mats.



Spoerer Car Is Modeled After the Mercedes (German)

SIXES seem to have the call in the line of big cars now; at least, the number of announcements of this type seem to be in greater number than those of any other, unless it be the small car with the block motor. This being the case, one cannot help but think that the Munch-Allen Motor Car Company, DuBois, Pa., has shown wisdom in deciding to adhere to that style to the exclusion of all others. This is the case, however, and the builders of the Keystone Six announce two models, both sixes, for the season.

These include a large and a small model. The former is equipped with a sixty horsepower engine, the cylinders being cast individually, with the valve on opposite sides. This form of construction allows the use of an unusually large valve, the advantages of which are too well known to require additional comment. In this particular engine they have a clear diameter of 2¼ inches, and are operated by means of harmonic cams. These permit of an unusual range of speeds, from the lowest, 125, up to the highest, which is 2,000 loaded. Even this may be exceeded as a speed of 2,318 revolutions has been obtained running the engine light. A range of speed like this gives a similar range of speed to the car, without changing gears, and aptly illustrates the flexibility of the six.

Nickel steel is the material of the crankshaft, 1⅞ inches in diameter and running on seven long and large bearings. These are of die cast bearing metal and are positively lubricated.

Two Distinct Ignition Systems—To make certain of always getting a spark, two separate and distinct ignition systems are fitted, the magneto, a Bosch high tension, and a timer as well. They fire the compressed charge in the cylinder through the medium of twelve spark plugs, all set into the inlet side of the engine. This position was selected as likely to reduce the chances of fouling the sparking points.

The engine is water cooled, with the water circulated through integral jackets by means of a large gear pump, gear driven as well. A large radiator of the tubular type, with square tubes, and of a very pleasing shape is employed to cool the water. Back of this is placed the rapidly rotating fan of six blades, belt driven from the camshaft. The whole comprises an unusually efficient cooling system, and one that is dependable as well.

Following the best foreign practice, a multiple disc clutch is used to transmit the engine power back to the transmission. This is enclosed in a drum bolted to the rear side of the flywheel. Thirty-two conoidal discs are used, and run in a bath of oil. The enclosing of the discs gives this desirable feature of oil bath lubrication at all times, and by making the case dust proof an additional point is gained.

Highest Grade of Materials Used—The material of the transmission parts is symbolical of the material of the entire car, which is of the very highest grade obtainable. Thus, the gears and shafts are of chrome nickel steel, and are mounted upon Timken roller bearings of ample size. The gear box affords three speeds and reverse, operating on a selective quadrant. This gear shifting means is so interlocked with the clutch control that gears can only be changed while the clutch is out. This is a positive and perfect preventative of stripped gears, the bugaboo of many an amateur. Moreover, the interlocking is retroactive in that the clutch may not be let into engagement unless the gears are in mesh—that is, it prevents clutch engagement when the gears are out of mesh.

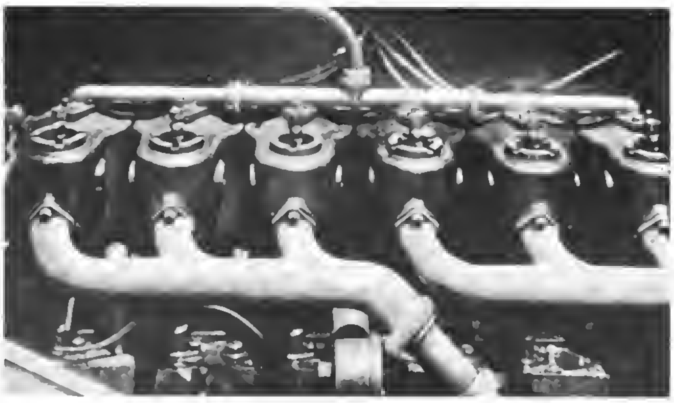
From the transmission the drive is through a single inclosed universal joint, and then through enclosed propeller shaft to the final reduction. This is a pair of bevel gears, of large diameter to insure smooth and quiet running. They are of four pitch and two-inch face. The differential is of the bevel style. Steering is effected by means of a worm and complete gear. The steering post is inclined at a small angle with the horizontal which gives the car a low, fast appearance. To this is fastened the steering wheel, 18 inches in diameter, constructed of aluminum, webbed for strength. On the steering wheel, upper side, are mounted the spark and throttle levers, these working on a stationary quadrant. Three foot pedals and the usual two side levers complete the control.

The right foot operates the service brake pedal, and the left the clutch, both pedals being made with adjustable pads, so that their height may be arranged to suit the physical convenience of the driver. A small toe pedal operates the accelerator, but this is only intended for use in close traffic and on rough roads. The inside lever controls the gears, and the outer, the brakes.

These last are of the internal variety, 14 inches in diameter by 2 inch face, working on large diameter drums bolted to the rear wheels. They are actuated through equalizers, which secure an equal pull on both brakes, regardless of road or other conditions. These also allow of unequal adjustments without disturbing the equality of the braking pulll.

With a wheel base of 122 inches the cars have a very long, roomy appearance. Large tires are used, 36 by 4 all around. The frame is of pressed nickel steel, narrowed at the front. Complete the six-sixty sells for $2,250, and is guaranteed for one full year against defects in material or workmanship.

The company is also placing on the market a light six-cylinder car of the same high-grade materials and workmanship. This is equipped with a 35-40 horsepower motor, magneto, disc clutch, selective gear box, and will have 117-inch wheel base and standard tread, with 34 by 3½ inch q. d. tires on all four road wheels. The weight of the little car is but 1,900 pounds.



Keystone Six Engine Has Two Separate Exhaust Pipes

QUARTER MILLION FOR AVIATION PRIZES

PARIS, July 7—A shower of gold—no less than $240,000—has fallen on the aviation movement. Henry Deutsch de la Meurthe, who joined with Ernest Archdeacon in offering the $10,000 won by Henry Farman in 1907, is responsible for $100,000 of the amount just donated to the University of Paris. The gift has been made for the purpose of founding an aeronautical institute in France, under the control of the University of Paris. To this amount the donator has added an annual subvention of $3,000, and the University has supplemented this by a further subvention of $2,000.

M. Deutsch de la Meurthe

In addition to these amounts, a rich Greek, Basil Zaharoff, has offered the sum of $140,000 to the University of Paris, the revenue from which shall be devoted to maintaining a professor of aviation at the University.

The two generous donations do not please everybody, for a certain group of aviators have for some time been harboring the scheme of making an appeal to the French nation for several million francs to found a national aeronautical institute. Deutsch de la Meurthe and Andrew Carnegie were to be approached for large sums with which to head the list, and the public was to be appealed to immediately after the aeronautical races at Rheims next month. By these two donations to the University the public appeal practically becomes impossible, to the disappointment of those responsible for the larger movement, for they declare that the amount given is insufficient to do any real and lasting good.

ENGLAND'S BUGABOO NOT A GERMAN CRAFT

LONDON, July 7—Stories concerning a mysterious air craft that was seen by night in various parts of England, notably in Suffolk, have turned out to be true and the ship a reality, it belonging to Dr. B. M. Boyd, the managing director of a firm of motor engineers. The first time the ship was seen was on May 18, at Belfast. The doctor now admits that he crossed the Irish sea on that date. While the craft has not been examined, it is said to be a dirigible balloon 120 feet long with a cigar-shaped gasbag divided into three compartments and driven by a 300-horsepower motor. The doctor has submitted plans to the War Office and will increase the length to 200 feet and the power to 500 horsepower before giving any exhibition. Experiments in this direction have been going on since early in March, and Boyd says he has made a trip of over 300 miles without stopping. The recent scare concerning the unpreparedness of England in aeronautical matters has been mollified by this announcement.

NOTED AMERICANS TO ATTEND AERO RACES

PARIS, July 6.—Jefferson de Mont Thompson, former chairman of the A. A. A. racing board, after spending a week in Paris, has now left for an automobile tour through Germany, Austria and Holland, returning to France in August to be present at the Gordon Bennett and other aeroplane races to be held at Rheims from the 22d to 29th of that month.

Cortlandt Field Bishop, president of the Aero Club of America, is also in Paris at present, but will leave shortly for Rheims in order to occupy himself with the necessary arrangements for the reception of the Herring-Curtiss aeroplane to compete at Rheims and elsewhere. Mr. Bishop, who is interested in the Herring-Curtiss Company, declares he will enter the machine for every race in Europe, including the crossing of the English Channel.

LATHAM PREPARING TO CROSS CHANNEL

PARIS, July 7—Twenty miles of water seyarate France from England—twenty miles which will doubtless be crossed by a gasoline engine and a couple of artificial wings before the month is out. There have been numerous aviators possessed with a desire to connect the Continent with John Bull's tight little island, but up to the appearance of Hubert Latham none have gone from desire to acts.

The Frenchman with an English name—for Latham though descended from British stock is a fully fledged Frenchman—took lessons on an Antoinette monoplane a few months ago. He was possessed of extraordinary daring, and after a few flights he held the French record, only being eclipsed by Wilbur Wright in ability to stay in the air. While Wright, however, is the embodiment of caution, and would not attempt to cross the Channel under any conditions, Latham sees no danger in such a hazardous trip. Instead, therefore, of continuing his training over the plains of Chalons, he has shipped his machine to the neighborhood of Calais, and as soon as everything is in readiness and the weather is right will take his flight from the high French cliffs with the object of settling on the shores of England.

The machine he will use is a monoplane, built by the Antoinette Company, and engine by the same firm, the power plant consisting of a 50-horsepower, eight-cylinder, water-cooled engine. At Chalons the machine has shown itself possessed of remarkable speed and stability, its pilot performing evolutions with it that have never been attempted since Wilbur Wright demonstrated at Le Mans.

To cross the Channel it is only necessary to remain in the air 35 to 45 minutes, according to the strength of the wind. The distance, however, is not the greatest difficulty, Latham having already flown distances equal to three crossings of the narrow strip of water. It will be impossible to make the trip in a dead calm, even if advantage is taken of a calm for the start, while it remains to be seen if the aeroplane can battle against the strong winds which usually blow in the English Channel as successfully as the more moderate breezes in which it has flown over land. A service of motor boats will follow the aviator, while the French government will allow torpedo boat destroyers to lend assistance.

Comte de Lambert, the first of the Wright pupils, intends to make an attempt to fly the Channel, but will not begin the construction of his shed until July 15, flights, therefore, being impossible before the end of the month or early in August. Since the Wright brothers returned to the United States very little has been done with their machines, the only flight of importance being made on Wilbur Wright's old machine by Paul Tissandier, who remained in the air a little over an hour.

AERONAUT SAILS OVER NEW YORK CITY

New York City enjoyed a free circus stunt Monday morning. The star performer was Frank W. Goodale, assisted by his dirigible balloon. Goodale has been giving exhibition flights at Palisade Park, a resort on the New Jersey side of the Hudson, and on this occasion, the weather being favorable, he decided to visit the city. He crossed the Hudson at a high elevation to escape the cold air currents, and then, descending to about 100 feet, followed Broadway down to Times Square, racing with the trolley cars. What is more, he got back to Palisade Park under his own power, without having to call in the services of a ferryboat. That afternoon Goodale started for the Polo Grounds, hoping to see the ball game without paying admission, but a strong wind turned him back. Goodale is a pupil of Roy Knabenshue, who several years ago sailed from Central Park around the Flatiron building and back.

Glenn Curtiss, with the aeroplane which he flew successfully for the Aeronautic Society, made three short flights of two or three minutes each on the grounds at Mineola, L. I., Tuesday.

NAZARRO'S RECORD ATTEMPTS FRUITLESS

London, July 2—The race meeting at Brooksland on Wednesday proved unsuccessful in its main featuré—the record attempts by Nazarro on the big red Fiat. This monster, whose cylinders are said to exceed 190 mm. in bore, is far and away the most powerful car yet turned out from the Turin factory, and speeds in the neighborhood of 130 m. p. h. were anticipated. During trial spins a 120-mile an hour gait was recorded for several laps, but a defective cylinder prevented 110 miles an hour being exceeded at the record attempts. The car was therefore withdrawn, but Nazarro, who certainly is not one to boast, states his confidence in the car's capabilities.

The Montagu Cup race brought out several Grand Prix cars, but finally a newcomer in the shape of a 70-horsepower Bianchi won with ease at an average speed of 84 miles an hour.

Both novelty and excitement were combined in the Taxi race, in which a score of the best-known British motorists were mounted on 12-14-horsepower Fiat taxicabs. The race was a close thing right through, Harvey du Cros, of Dunlop fame, beating Chas. Jarrott for first place by a couple of yards.

The Grand Prix sweepstakes proved another disappointment, for of the four entries Astley's Napier came to the line too late to start and Stirling's Brasier was stopped in mid-career with a fractured fuel pipe. The other Napier, driven by Baker White—who also owns the monster Fiat—won after a lengthy struggle with Rose's Weigel.

Several other handicap races were run off, one of these being won by an old De Dion voiturette which had been a contestant in the ill-fated Paris-Madrid race years ago.

Curiously enough, while the race meetings themselves have been singularly free from accidents during the past year, two unfortunate occurrences have taken place since Wednesday. Immediately after the last race of the day, Cook, riding an N. L. G. 7-horsepower motorcycle, was thrown off when traveling at over 70 miles an hour down the finishing straight. The pneumatic skull cap which he was wearing saved his life and his injuries were confined to a broken arm and sundry bruises.

The other accident occurred yesterday and was more seriouus. An amateur driver was trying the paces of Astley's big Napier and after coming along the finishing straight attempted to turn the sharp corner leading back to the main track. The car promptly rushed up the banking and overturned. The driver was almost unhurt, but the passenger was very badly injured.

GUINNESS STILL RUNS 8-CYL. DARRACQ

London, July 2—Speed trials on the various beaches of the eastern and southern coast lines, once most popular, have lately been of rare occurrence, so that special attention was paid to the meet promoted by the Yorkshire A. C. at Saltburn, on Saturday last. The numerous races for touring cars were well patronized, but, as usual, interest was centred on the performances of the racing cars. Of the "four-inch" cars, Colmore's Darracq did extremely well by averaging 67 miles an hour for the kilometer. Tate won the race for Grand Prix cars, his speed being just under 95 miles an hour. Finally came Lee Guinness, alone in the "free-for-all" class, with his eight-cylinder Darracq of Florida fame. The best of four runs over the kilometer averaged 120 1-4 miles an hour, the mean speed for the four attempts being 118 miles an hour. This is a European record, although not equal to the 122 miles an hour speed recorded by Guinness at Saltburn last year, but which was not recognized by the R. A. C.

SCOTTISH TRIAL AWARDS ANNOUNCED

Glasgow, June 30.—The Trials committee have awarded the efficiency gold medals as follows:

Class A	10 H.P.	Riley	990	marks.
" B	18 "	Riley	977	"
" C	10-12 "	Humber	996	"
" D	14-16 "	Argyll	986	"
" E	16 "	Humber	995	"
" F	24 "	Vauxhall	995	"
" G	30 "	Adler	977	"

Total marks were 1,000 in each class.

The Scottish Cup, awarded to the car showing least fuel consumption for the whole distance, was awarded to the 38-horsepower Knight Minerva, with a consumption of .0224 gallons per ton-mile, equal to 44.6 ton-miles per gallon. In car miles this is approximately equal to 25 miles per gallon.

MONTREAL RACE ENDS FATALLY

Montreal, July 12—The danger of automobile racing on horse tracks was again exemplified at the second annual meet of the Canadian Automobile Club on the Blue Bonnets track last Friday. The victims were C. K. Batchelder, of Newport, Vt., and J. Twohey, of Montreal, driver and mechanician respectively of Lorne Hale's Stearns in the 10-mile open race. On the eighth mile the car swerved through the fence in attempting to pass a contestant, and both men were killed. The exact cause of the accident cannot be determined. Burman, on his Buick, won four of the nine events, and De Palma, after an ineffectual attempt to beat the mile record with the Fiat Cyclone, won the free-for-all. The track was in good condition, and there was a large crowd.

Orville Wright made two unsuccessful flights Tuesday evening at Washington, neither lasting more than a few hundred yards. The wind was unfavorable, and he could not get sufficient speed or elevation to direct his course satisfactorily. The second flight started more favorably than the first, but again Wright came to the ground rather than attempt the turn. This time, however, he did not stop the motor quickly enough, and the aeroplane came down with some violence, breaking the left runner. The injury will not delay the trials.

GREAT REVIVAL IN USE OF ELECTRICS

Of late a gradual tendency back to the electric vehicle for city use has been very noticeable. This was evident from the increasing number in use in the larger cities, in the returns from manufacturers, from the increasing number of communications dealing with the subject, and from other sources, none the less well-defined, though perhaps small.

Considering this, then, the reappearance of the "improved" Edison battery is probably very well timed, since the claims for this, less preposterous than some of its predecessors, are simply increased discharge per unit weight. Even this is admitted to be obtained at a rather large loss between the total charging and the discharge current. However, since tests of this battery, technically known as the nickel-iron cell, have shown a very superior output over the old cells, it may be well to look into the fact that this will have a large and favorable effect upon a branch of the automobile business now experiencing a marked revival. At the very least this should add impetus to that revival, and as time proves the truth of the first tests, and, perhaps, improves upon them, it may become a stepping stone to a greater electric vehicle business, both pleasure and truck.

The fault with the electric has always been limited range or the inverse, excess dead weight. The new nickel-iron battery, if it doubles the output for the same weight, will alter one of these. For limited distance use this will reduce the useless dead weight to one-half, and in cases where the weight is not so objectionable, placing it at the same figure as before, places the radius of obtainable action at double the previous mileage. Inasmuch as this has upon numerous occasions been set up to over 100 miles, doubling it would bring the figure up to about the maximum ordinarily obtained in a day's travel. This, then, would place the electric vehicle upon a par with its gasoline rival, a state of affairs long sought after and never obtained.

It is with bated breath, then, that the manufacturers and well-wishers of the electric car await future tests of the new nickel-iron Edison battery.

In so far as the electrical car, at best, must so conserve its energy as to attain the maximum result either of speed or mileage from a given weight of battery, anything which will conduce to an extension of that conservation is of immediate interest. So, it is that a new type of tire especially designed for use of electrical vehicles is worthy of mention. These are made with very thin walls and are of the single tube type, popularly called "hose pipe." They may now be had in the detachable form. The low speed, comparatively, at which electrics operate allows the use of these thin-walled tires with very satisfactory results. A combination of the low-wattage tires with the new nickel-iron battery should give to the business as a whole such an impetus as it has not received in many years, if ever. Both instances just go to show that the work being done upon electrical cars is of great value to the person who uses them.

FRANCE STILL LEADS IN AVIATION

While the Signal Corps officers at Fort Myer are anxiously waiting for the Wright brothers to impress on Congress the practicability of their aeroplane in the hope of securing a reasonably generous appropriation, word comes from France that the University of Paris has received endowments amounting to a quarter of a million dollars for the purpose of encouraging progress in aviation, and that, still unsatisfied, certain leaders in the new science hope to obtain an even larger sum from the government for the foundation of a special institute. Truly a contrast!

The sceptical attitude affected by Congress is fast making that body ridiculous. Years ago, when the Wrights were called indifferently "cranks" or "bluffers," the War Department laughed to scorn their proposals; yet it cannot really be blamed. To-day, after they have abundantly proved every claim and made themselves famous the world over, Congress still doubts. The incredulity of the War Department cost us the exclusive use of the Wright aeroplane. Congress may well profit by their lesson and save us what is left.

The United States has far more need of an aeronautical institute than has France. With the exception of the Wrights, who belong no more to us than to any other country, our inventors who have succeeded in lifting themselves off the ground by mechanical means might be counted on the fingers of one hand. In France they are numbered by scores, and, far from being copyists, they are constantly evolving new types and experimenting in new directions. For once Yankee ingenuity seems outdone, and Congress, instead of helping us regain supremacy in the science of the future, discusses the tariff on collar buttons.

DATE SELECTED FOR GOOD ROADS CONVENTION

MOST important to all concerned over the progress of good roads was the conference recently held in Cleveland. At this meeting of the American Automobile Association officials and the members of the Good Roads Board, the dates September 21 to 23 inclusive were selected for the Second Annual Good Roads Convention. This will also be held in Cleveland.

The United States Government has shown its keen interest in the beneficial results to be accomplished through the convention by delegating as its official representative Logan Waller Page, director of the U. S. Office of Public Roads. Co-operating also with the A. A. A. will be the National Grange, the American Road Makers' Association and all of the automobile organizations representing the various manufacturing interests.

Chairman Geo. C. Diehl, of the A. A. A. Good Roads Board and the National Convention Committee, Lewis R. Speare, president, and F. H. Elliott, secretary, of the A. A. A., and W. F. Bonnell, president of the Cleveland Automobile Club, were among those present at the conference. Among the other members of the National Convention Committee are James H. MacDonald, president of the American Roadmakers' Association; S. D. Waldon, president National Association Automobile Manufacturers; Alfred Reeves, General Manager American Motor Car Manufacturers' Association; Robert P. Hooper, ex-chairman A. A. A. Good Roads Board; Charles Thaddeus Terry, chairman A. A. A. Legislative Board, and N. J. Bachelder, president of the National Grange.

Governor Harmon of Ohio has consented to represent his State at this convention, and he will speak on the Good Roads in Ohio. Mayor Thomas L. Johnson, of Cleveland, will deliver the address of welcome. Congressman R. P. Hobson, of Alabama, will deliver an address on "National Aid and Post Roads." Among the other speakers selected for the tentative programme with their subjects are:

The National Grange and Good Roads—N. J. Bachelder, Master of the National Grange.

State Aid—James H. McDonald, State Highway Commissioner of Connecticut.

Economics of Road Building—Samuel E. Hill, President National Goods Association.

Road Situation in the United States as Compared with Foreign Countries—Logan Waller Page, Director U. S. Office of Public Roads.

Macadam Roads—A. B. Fletcher, Secretary Massachusetts Highway Commission, or some other speaker to be selected by the Massachusetts Highway Commission.

Bituminous Road Materials—Provost Hubbard, Chemist of the U. S. Office of Public Roads.

The closing day of the convention will be devoted to a series of important tests on macadam roads to determine the best methods of counteracting the dust problem, and there will also be practical demonstrations with different materials of road building conducted by Director Logan Waller Page. The Cleveland Automobile Club will take the delegates on a tour of inspection over the improved roads in the vicinity of Cleveland.

PREPARING BRIGHTON BEACH TRACK FOR RACES

BRIGHTON Beach race track had a hairbreadth escape from being parceled out into building lots this Summer. A gang of workmen were already busy tearing down fences when the Motor Racing Association, of New York City, announced that it had signed a lease for the property. This association, it will be remembered, conducted two successful meets on the track last Summer. For this Summer's events the turns will be banked and the homestretch widened, and the entire track will be rolled hard and treated with a dust-laying compound. A new field stand will also be erected.

The first meet on the restored track is scheduled for Friday and Saturday, July 30 and 31. It will include a twenty-four hour race, limited to sixteen entries. More than half this number have already been pledged, although the entry blanks have not yet been issued. On the opening day, July 30, a number of short events will be held, and also, if it can be arranged, a 200-mile race for cars not eligible for the twenty-four hour contest. Opportunities will be provided for cars of all sizes and descriptions to show their mettle. The long race will start Friday evening, ending Saturday in time for the usual half-holiday crowd. The management will endeavor to have an elevated express station established at the race track, to give convenient transit.

A. B. Cordner, of the Cordner Motor Car Company, will be chairman of the race committee, and will have as his assistant T. F. Moore, organizer of the Briarcliff race and manager of the races at Brighton Beach last year. Their headquarters are now open at 1540 Broadway, New York. Mr. Cordner intends to have the work of reconstructing the track pushed forward as rapidly as possible, so that entrants may have an opportunity for practice before the opening meet. The membership of the Motor Racing Association includes C. F. Wyckoff, handling the Stearns; A. B. Cordner, Acme; E. R. Hollander, Fiat; C. H. Page, Chalmers-Detroit; H. A. Lozier, Lozier; W. B. Hurlburt, Thomas; Paul Lecroix, Renault; H. S. Houpt, Herreshoff; C. A. Singer, Palmer-Singer; W. F. Sykes, Zust, and W. C. Allen, Allen-Kingston. The makes handled by the members are expected to form a nucleus and insure a good field, but the entry list is to be open to all without favor.

ATLANTA TO HAVE A TWO-MILE TRACK

ATLANTA, GA., July 12—Without the usual blare of publicity, a body of Atlanta men have for some time been working on a two-mile automobile race track, which it is expected will be one of the finest in the country. The Atlanta Automobile Association is in charge of the enterprise. According to Secretary E. M. Durant, $300,000 has been raised, and 500 men, with three steam shovels and 200 teams are now busied on the excavation.

The plans call for a track two miles in circumference, one hundred feet wide on the home stretch and sixty feet elsewhere, the turns to be scientifically banked. The track will be opened with a series of international races on November 9, during the week of the Atlanta automobile show and the New York-Atlanta endurance run.

PRESIDENT TAFT INVITED TO LOWELL

BOSTON, July 12—An invitation has been extended to President Taft by Governor Draper and other prominent officials of Massachusetts and the officers of the American Automobile Association to attend the automobile carnival at Lowell, Mass., during the week of September 6. President Speare of the A. A. A., whose home is in Boston, was one of those who signed the invitation.

COLUMBUS, O., ENCOURAGED BY SUCCESS

COLUMBUS, O., July 12—Because of the success of the races of the Columbus Automobile Club on July 2-3, it has been decided to hold another meet some time in September. The racing committee of the club is now at work on the details.

INCREASING POPULARITY OF AUTOMOBILE CONTESTS

By BENJAMIN BRISCOE, President, Manufacturers' Contest Association.

At no time in the history of the American Automobile Association has there been such a demand for sanctions as this year. These sanctions cover every conceivable kind of tests, such as reliability tests, fuel economy tests, hill climbs and track races, both at long and short distances. The mere fact that an unlimited number of sanctions are being granted is not so interesting in itself, but it brings to mind the fact that there is a widespread demand for competitive events.

Each local event held is under more strict regulations than its predecessors, which goes to prove that each season's product is better than the last or else the cars could not make the wonderful showing which they do. Never has the self-propelled vehicle been given such rigid tests and exacting mechanical scrutiny. When an event is held the technical committees are made up of men who thoroughly know the car from the motor back to the differential, and the car of to-day must be mechanically right before it can stand an examination such as is given to the cars nowadays.

It seems to be the desire of the public to see all the competing cars "killed off," or, in other words, have rules so rigid that none can finish with a perfect score. This not only means more for the cars themselves if given a high percentage, but it encourages competition inasmuch as that no discredit falls on the maker if his car fails of a perfect score. Misery always likes company, and if there are not any perfect scores or few high percentages, those with lower scores do not regret entering, as would be the case if the rules were so lenient that several finished with no demerit marks.

With so many events being sanctioned from the Atlantic to the Pacific and from the Great Lakes to the Gulf of Mexico, it is evident that the motor car industry is in an unusually flourishing condition and that the public is interested in and believes that road and track events are good barometers for getting an idea of what the present-day car can do in competition with rival makes.

Judging from the interest taken in the various road and track events, it is evident that the public care more for fuel and reliability tests than it does for track racing, or, at least, track races at short distances. Any car can travel a distance of five or ten miles on a track at a good rate of speed. The public do not buy cars as a rule for speed, but for power and durability. Track events, unless those of 100 miles or such as the 24-hour race, do not bring out the staying qualities and endurance of the machine as do road events such as the Glidden tour or the three-day run of the New York Automobile Trade Association through the Catskills and Berkshires.

While thousands will flock to the racetrack to watch short distance racing, it is because of the fascination of seeing the racing cars whirl around the track at a great burst of speed. I doubt, however, if there are many purchases made on the strength of the speed developed in track races. There is no question but that sales are made through the results of fuel and reliability contests, as a car which can stand up under the exact mechanical examinations, both before and after the test, demonstrates to the public that if they can endure under the rigid regulations of the contest they will answer every purpose for touring under general conditions.

It seems to me that makers and the public should encourage and support all wholesome road endurance contests, as it not only demonstrates to the public what the car can do, but each event teaches the maker wherein he can make his product stronger and more durable.

FAST RACING IN SOUTHERN CALIFORNIA

Santa Monica, Cal., July 12—Two of the fastest stock car races ever run in this country were brought off here last Saturday in the presence of more than 50,000 spectators. They were held over a course 8.4 miles to the lap, and the good condition of the road is vouched for by the phenomenal times recorded. An Apperson "Jack Rabbit," driven by Harris Hanshue, won the $1,000 Dick Ferris trophy, covering the 202 miles in 3:08:03, at an average of 64.2 miles an hour. Bruno Seibel's Chadwick took second place, and a Stearns third. In the small-car race, at the same distance, Bert Dingley brought his Chalmers-Detroit across the tape in 3.38:35, winning the Leon Shettler cup.

MILWAUKEE PLANNING A SEPTEMBER MEET

Milwaukee, Wis., July 12—The Milwaukee Automobile Club has been advised that it cannot have the use of the State Fair Park track until after September 17, the closing day of the fair, and all plans for a meet before that date have been dropped. The annual meet, which will probably include Milwaukee's third twenty-four hour race, will be one of the biggest in the Northwest, as the club's racing board will hang up big purses and invite the leading drivers of the country.

BALTIMORE HAS TWO EVENTS SCHEDULED

Baltimore, July 12—As many Baltimoreans and Washingtonians are away from town during July and August, the Motor Car Racing Association of Maryland has decided to postpone its twenty-four hour race at Benning, D. C., from July 16-17 to September 10-11. The program will be as originally planned, including on the first day six stock-car races at varying distances and a ten-mile record trial, and ending with the long event.

RACES AT OAKLAND, CAL., WELL ATTENDED

San Francisco, Cal., July 12—In the races of the Oakland Athletic Club on the Emeryville race track last week Buick, Mitchell, Cartercar, Comet and Detroit electric carried off the honors before a large holiday crowd. Inefficient policing caused the death of a spectator who attempted to cross the track, with the usual result. The driver of the automobile was stunned, but not seriously hurt. Although the racing was not of the record-breaking order, it satisfied the crowd. The best event of the day was the ten-mile free-for-all, which Christianson on a Buick won from Cooper's Comet after a close and exciting contest.

STRANG CUTS THE FIFTY-MILE RECORD

Springfield, Ill., July 12—At the Illinois State fair grounds last Saturday Lewis Strang, driving a Buick, broke the world's fifty-mile circular-track record which he established at Columbus, O., recently. The new record mark is 52 minutes, 48 seconds, a reduction of nearly a minute. His fastest mile was made in one minute, one second. Strang, however, lost his five-mile race with Chevrolet, the latter's time being 5:51. The stock car races also provided some interesting contests.

COLUMBIA, S. C., SEES A HILL-CLIMB

Columbia, S. C., July 12—A good crowd turned out for the annual Fourth of July climb on Monticello Hill, and saw some close racing. In the event for cars under $1,500, McMaster's Ford carried off the prize, with a Buick and a Ford tied for second. An Aerocar driven by Gibbes won the free-for-all, a White taking second. An unusual and highly commendable feature of the day was that the trials were started on time.

FRANKLIN WINS BUFFALO'S ONE-GALLON ECONOMY

BUFFALO, N. Y., July 12—Howling success best describes the one-gallon fuel economy contest held by the Buffalo Automobile Club recently, for in this not only was a distinct winner evolved in each class, but a contest winner as well, the latter, the Franklin 1910 model, breaking all economy contest records at the same time. There were four classes, with a professional or manufacturer's division and an amateur's division in each.

These drew twenty entries, all starting, and all but one finishing, this one being so delayed by a puncture that it was impossible to finish within the scheduled time. A fine course had been laid out by the club officials, 16.5 miles in length, straight out Main street from the club headquarters to Williamsville. This made the round trip 33 miles, but in this they reckoned without their host, for six of the competitors started on the third trip, while the winning Franklin came within 4 miles of starting back over it a fourth time.

Driver Averell and the Winning 1910 Franklin Car

There were four classes, divided according to the new price classification, but Class B, $1,000 to $2,000, was the only one that filled properly, and it was in this class that the real contest was found, this furnishing the winner as well.

The latter was S. G. Averell, driving a 1910 model G Franklin, and when this car, weighing all told 2,498 pounds, went 46.1 miles on the allotted one gallon of gasoline, it broke the record held by the same driver with a 1909 model G Franklin, made in New York exactly two months previous. In the latter case Averell went 35.8 miles with a weight of 2,880 pounds, giving a score of 103,104 pound miles, or 51.55 ton miles. In the Buffalo run this record was 135,902 pound miles, or 67.95 ton miles.

A single-cylinder Brush made the second longest distance of the day, but owing to its very low weight, 1,432 pounds, the smallest in the contest, it was beaten in its class by Parkhurst's Reo, which went 5.8 miles less but scored 12,368 points more, equal to 6.19 ton miles.

Figures for the run compiled by John M. Satterfield, of the Buffalo club, show that the total ton miles were 646.5, which with gasoline at 15 cents per gallon makes the average fuel cost 4.4 mills per ton mile, and the lowest figure 2.2 mills per ton mile. The total passenger mileage was 1,785.2 on 19 gallons of fuel, which works out to an average cost of 1.59 mills per passenger mile. All of the cars were water cooled except the winning Franklin, and all had special tanks for the fuel.

WASHINGTON-BOSTON RELIABILITY CONTEST

WASHINGTON, D. C., July 12—The chain of newspapers owned by Frank A. Munsey, the publisher, is the prime mover in a reliability contest scheduled for the week of September 22-29. The event will be known as the Munsey reliability contest, and the route will be from Washington, D. C., to Boston and return, taking in Baltimore, Philadelphia, New York, Albany and Springfield. The contest has been sanctioned by the A. A. A., and the officials of that organization have expressed the belief that it will prove an important Eastern event, filling the gap caused by the running of this year's Glidden Tour in the West. Entries are now being solicited by the representatives of the Munsey papers. Two were secured in Detroit last Friday—a 1910 Chalmers-Detroit, which Joe Matson, winner of the Indiana trophy, will drive, and a 1910 Hudson roadster, entered by the makers. The pathfinding car will be the Chalmers-Detroit flag-to-flag car, which has just returned to Detroit from its strenuous trip.

CALIFORNIA CLUBS PLACING ROAD SIGNS

RIVERSIDE, CAL., July 10—Through the energy of the automobile club here in starting an energetic campaign to place legible signs on all the popular touring roads in its locality, the board of supervisors of the county lately became imbued with the same spirit of progressiveness and appropriated $1,000 for road signs. The Riverside Automobile Club will contribute another $1,000.

Table of Results and Details of Cars Competing in Buffalo One-Gallon Economy Contest

NEARLY 20,000 REGISTERED IN MASSACHUSETTS

BOSTON, July 12—All previous records for automobile registration in Massachusetts have been broken, for during the first six months of this year, ending June 30, more cars were registered than during the whole of last year. The total registration last year was 18,025, and on July first this year 19,322 machines had been registered with the Highway Commission. And the rush for certificates continues so strong that the commission is about 500 behind in the issuance of number plates, though its clerks are working nights. There has been little abatement in the demand from owners of cars, the number registered on the last day of the month being 121, while for the last two weeks in June the registrations averaged 86 daily.

It is figured that under the new law with the sliding scale plan of registration, the revenue from the same amount of business that has been transacted since January 1 of this year would be $100,000 greater. The Highway Commission estimates that about 54 per cent of the cars will pay the $5 fee, 25 per cent the $10 fee, 13 per cent the $15 fee, 6 per cent the $20 fee, and 2 per cent the $25 fee. On this basis the 19322 machines registered so far this year would pay $171,005 instead of $96,610. In addition there will be greatly increased revenue from licenses as they become annual.

The receipts of the automobile department have shown a corresponding jump and for six months are ahead of the total of last year, and nearly $23,000 ahead of the receipts for the first six months of 1908. Up to last Thursday morning there had been turned over to the State Treasurer by the Highway Commission for road maintenance fees aggregating $127,913.50, against $105,201 on the same date last year. In motor cycle registrations, manufacturer's and dealer's registrations and licenses to drive the figures are much ahead of last year, as shown in the following comparison for July 1, 1909, and July 1, 1908:

Registration	1908	1909
Automobiles	14,547	19,322
Motorcycles	1,492	1,872
Manufacturers and Dealers	359	461
Licenses		
Private Operators	3,212	4,855
Chauffeurs	3,444	5,037
Receipts	$105,201	$127,913.50

It is estimated that since 1903, when the first automobile law was passed, and in which the private operator's license was made perpetual, about 30,000 people have been licensed in Massachusetts to drive automobiles. There are approximately 7,000 licensed chauffeurs. Many tens of thousands of dollars will also be added to the State highway funds by the diversion of the fines received from motorists to the State.

Only a part of the new law is now in effect, but motorists are well pleased with the way in which it is working and believe that when the whole is in operation Massachusetts will have the best auto law ever put on the statute books of any State.

NEW BOOKS FOR AUTOMOBILISTS

"American Cyclopedia of the Automobile"—In the six volumes published under this title will be found not only a new and excellent method of treating the subject matter, but much that is new and different in the way of description of automobile parts. So full are the descriptions, that possessing one of these encyclopedias, one would have no further use for the numerous instruction books, troubles, diseases, and repairs being treated very fully in turn, under their respective heads. Of the six volumes, the first five are concerned wholly with cyclopediac matter, from the first definition of volume one, A. A. A., the abbreviation of American Automobile Association, to the last of volume five, Zylonite, same as Xylonite, another name for celluloid. The last, or sixth volume, is more on the order of interesting reading, for it is devoted to the history of the automobile, in which it is the most extensive that has ever been written. Following this naturally some space is given over to a description of the road and track races which have taken place, this being written in an historical fashion. A few pages are also allowed for an intelligent though brief résumé for the legislation pertaining to the automobile, while the windup is Study Helps. The latter consists of questions and answers, so arranged as to produce a steady, forward progress in the knowledge of the automobile from the very rudiments to the highest theory, and complete construction. The writers number the best men in the country, including Charles E. Duryea, C. P. Root, Thomas H. Russell and Victor Lougheed. It is being placed on the market by Bacon & Fynney, 121 Bolyston street, Boston.

"Accidents and Emergencies"—Everyone should have a book of this sort, not only automobilists, but everybody engaged in work around machinery, or wherever there is a liability of accident. The title and sub-title, a manual of the treatment of surgical and medical emergencies in the absence of a physician, indicate clearly the scope of the work. Into 200 small pages the publishers, P. Blakiston's Son & Co., Philadelphia, have crowded a wealth of valuable information on the subject of first aid. A brief glance at some of the chapter headings will give an idea of the worth of this little volume.

AUTOMOBILE CALENDAR OF EVENTS

Shows, Meetings, Etc.

Aug. 5-7..........Chicago, Midsummer Meeting Society of Automobile Engineers.
Sept. 21-23.......Cleveland, Good Roads Convention, American Automobile Association.
Nov. 6-13.........Atlanta, Ga., Auditorium-Armory, National Automobile Show.
Dec. 31-Jan. 7....New York City, Grand Central Palace, Decennial International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

July 30-31........New York City, Brighton Beach, 24-Hour Race, Motor Racing Association.
July 31...........Richfield Springs, N. Y., Hill Climb, auspices of the "Earlington."
Aug. 5...........Chicago, Fourth Annual Algonquin Hill Climb, Chicago Motor Club.
Aug. 26-28.......Minneapolis, "Little Glidden Tour," Minnesota State Automobile Association.
Aug. 19-21.......Indianapolis Motor Speedway, First Race Meet.
Sept. 6-11........Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
Sept. 15..........Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-mile Race, Fairmount Park, Quaker City M. C.
Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

FOREIGN

Races, Hill Climbs, Etc.

Aug. 22-29.......France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Sept. 5...........France, Mont Venteoux Hill Climb.
Sept. 19..........Austria, Semmering Hill Climb.

MASSACHUSETTS PARK COMMISSION RAISES SPEED LIMIT

BOSTON, July 10—Although exempted specifically from the provision of the new automobile law which annuls all local speed and exclusion regulations in Massachusetts, the Metropolitan Park Commission today gave evidence of its desire to assist in the cause of uniformity of automobile regulation in the State. The commission controls many of the main arteries of automobile travel in the suburbs of Boston, its boulevards and parkways being the favorite avenues of travel in and out of the city on nearly every side. Heretofore the maximum rates of speed have been fifteen miles on the principal parkways and ten miles on others, with many roads closed to motor vehicles. By an order issued today, to become effective August 1, the maximum limit is increased to twenty miles an hour, which is the same as the maximum under the State law. No intermediate limits, as in the State law, are made, the commission being convinced that it is better policy for it to enforce rigidly the twenty-mile maximum and depend upon the reckless driving clause of the general law to curb driving at improper speeds in the more crowded parts of the parkways under its jurisdiction. The new maximum limit applies to all roads under the care of the commission to which automobiles are admitted. The commission, however, makes it plain that it does not consider twenty miles an hour a safe rate of speed at which to drive around curves, across intersecting streets and upon certain parkways where there is heavy travel by pedestrians and vehicles. The park police will be instructed to prosecute drivers who drive their vehicles in a manner to endanger the public, no matter what the rate of speed.

In addition to increasing the speed limit, the commission has opened several more park roads to motor vehicles. These include the Lynn Fells parkway in Melrose, a new road entering the Middlesex Fells reservation, the great public park to the north of Boston, the border road in Middlesex Fells reservation, between the Lynn Fells parkway and Wyoming avenue in Stoneham, and the road in the Quincy Shore reservation to the south of Boston. Other parkways upon which the speed limit is increased to twenty miles are the Middlesex Fells parkway and Revere Beach parkway, the main automobile road followed in going from Boston to Lynn, Salem and the north shore; Neponset River parkway in Milton, Charles River parkway in Watertown, a favorite automobile route; Lynnway, another part of the north shore route; Furnace Brook parkway, leading to the Blue Hills reservation, the great southern park of the Metropolitan system; the driveway of the Lynn Shore reservation and the driveway of the Revere Beach reservation. Furthermore the hours at which automobiles are excluded from the Revere Beach reservation driveway, formerly from 2 to 11 p. m. on Saturdays, Sundays and holidays from June 16 to September 14, are changed to from 3 to 10 p. m., allowing autoists two hours more during which they may use this important link in the chain of parkways to the north of Boston.

With these concessions by the Metropolitan Park Commission a uniform maximum rate of twenty miles an hour is established in Boston and vicinity and practically throughout the State. The rules of the Boston Park Commission, limiting the speed on its parkways to eight, ten and twelve miles an hour, were made void by the new automobile law, and in the new set of rules prepared by this commission and now before the Highway Commission for approval, no provision is made as to speed limits. Other cities and towns have not shown a disposition to enact special speed regulations, though some have passed rules excluding motor vehicles from certain highways where their presence is considered dangerous. As a whole, they show a welcome desire to be fair and reasonable.

GEORGIA INTERESTED IN PROPOSED LAW

SAVANNAH, GA., July 5—Automobilists of this State are waiting with interest to hear the particulars of a State automobile law, which is being compiled by Senator J. D. Boyd, of Griffin. This, it is expected, will be introduced at the Capital in a very short time, and will provide for the registration, licensing and speed regulation of the cars. It will also probably arrange for the registration of automobile drivers, and the license number to be carried will correspond, for the purpose of identification. President F. C. Battey, of the Savannah Automobile Club, has drawn up a bill which will be presented to the Council of this city, to govern autoists while operating in the municipality. It will arrange for the licensing of everyone who operates an automobile, after they have been examined by a board of commissioners. It would be necessary for the applicant to show a sufficient knowledge of the rules of the road, and mental and physical ability to run a machine. The commission would also have the right to revoke a license of anyone convicted of speeding, or other improper conduct, upon two or more occasions.

STATE WILL NOT GRANT REBATES

COLUMBUS, O., July 10—In a decision rendered by Attorney General Denman of Ohio, upon the request of State Registrar of Automobiles, Fred H. Caley, it is held that the State law gives no rebate to motor car owners for the time after the end of the year. According to the law, every license expires on the last day of December and a new one is required after the first of the year. For instance, a person securing a license in October can only use it until the end of December. Mr. Caley said: "Some regard this as an injustice, but it is the only way in which the automobile department can be conducted on a business basis."

MOTORCYCLE COPS TO ENFORCE LAWS

INDIANAPOLIS, IND., July 12—Local authorities are giving much attention to the regulation of automobiles. Two ordinances are now pending before the city council and a third will be introduced next week increasing the motor cycle corps from two to six officers.

Pending ordinances require the registration of automobile drivers, for which an annual fee of $1 is to be charged, and prohibits the driving of cars by any one less than seventeen years old. The measure also requires the use of mufflers, lights at night when cars are left standing in the street, and prohibits the running of machinery while cars are standing unattended. The motor cycle corps is used for running down violators of the speed law. Two officials are employed in the work but after August 1 there will be six men.

CONNECTICUT CLUBS OPPOSE NEW LAW

HARTFORD, CONN., July 12—The Connecticut Automobile Association has just issued a circular letter setting forth a number of objections to the new law at present under consideration in the legislature. It is claimed that the law is unjust to automobilists in the matter of taxation, and that altogether it is so complex that even a lawyer cannot find out what it really means. It is the consensus of opinion that it would be preferable to retain the law of 1907 at present in force. This is substantially what various members of the legislature have hinted at all along. They believe that the law is inadequate and that it would be well to prevail upon the Governor to veto the measure. Automobilists are numerous and well organized in this State, and it is believed that they will be able to defeat the measure, and secure a longer trial for the present law.

The Transcontinental Regal Leaving Detroit

While in Detroit on Friday of last week the Regal car, which is after the coast-to-coast record, was the recipient of much attention from the visiting Gliddenites. The picture shows the Regal lined up with a number of escorting cars, ready to make its departure from the "City of the Straits."

REGAL TRANSCONTINENTAL LEAVES CHICAGO

Chicago, Ill., July 13—George D. Wilcox, in command of the Regal which is making a transcontinental journey as a demonstration test of the 1910 model, arrived in Chicago late Monday night and left Tuesday morning on the second leg of its trip. Seven days out of New York, the car has covered 1,152 miles, running on its prearranged schedule with a daily average of 164 1-2 miles. So far the car has suffered but two punctures to its Empire tires, both coming in the same tire. After a night's rest here, the Regal started at 11 o'clock from the *Motor Age* office, bound for Clinton, Ia.

GENERAL MOTORS ABSORBS CADILLAC

Detroit, July 10—By far the largest deal in the local history of the automobile, if not in the trade at large, was consummated when negotiations pending for some time ended in the General Motors Company acquiring the Cadillac Motor Car Company. The price paid was between $4,500,000 and $5,000,000, stockholders in the Cadillac Company receiving slightly in excess of three for one on the $1,500,000 capital of the concern.

Back of this deal is an interesting story of how previous negotiations failed through a financial hitch. Some time ago the General Motors Company offered 160 for the stock of the concern. The proposal was viewed favorably by a majority of the stockholders, and it looked for a time as though the transfer would be made. Then came delay in securing money to finance the project, and it fell through. It is reported on good authority that the General Motors Company came back later with an offer of 200. In the meantime the Cadillac Company had been riding the crest of prosperity, and what would ordinarily be considered an exceedingly advantageous offer fell on unheeding ears. Then came the third attempt, which proved successful, and, incidentally, compensated the stockholders for the delay in closing the deal.

According to William C. Durant, chairman of the executive committee of the General Motors Company, and who conducted negotiations for that corporation, there will be no change in the management or factory organization of the Cadillac Company. The management of the company will be in the hands of W. C. Leland, with H. M. Leland acting in an advisory capacity.

The Cadillac Motor Car Company has one of the largest automobile plants in the world, and none is better equipped for the production of high-grade cars. Henry M. Leland, one of the founders of the concern, is a manufacturer of the old school, and under his direction automatic and time-saving machinery second to none has been installed.

The acquisition of the Cadillac Motor Car Company adds another to the string of factories taken over by the General Motors Company in the last few months. Those located in Michigan are the Buick Motor Company, Flint; Olds Motor Works, Lansing; Welch Motor Car Company, Pontiac; Reliance Motor Truck Company, Owosso; Rainier Company, Saginaw; Oakland Auto Company, Pontiac; Cadillac Motor Car Company, Northway Motor & Mfg. Co., and Motor Parts Company, Detroit.

Ten-year-old Mary Freda Brown at Wheel of Her Overland

This diminutive driver is the daughter of Will H. Brown, vice-president of the Overland Automobile Company, Indianapolis, and she has demonstrated repeatedly that she can handle an Overland with unusual dexterity. She recently drove her car in a parade in which 400 autos participated. During her trips she is always accompanied by her young brother Albert and the factory mascot, a pet dog called "Overland Bob."

Sir Lomer Gouin in his Six-Cylinder Stevens-Duryea

As was noted in last week's issue of "The Automobile," the popular Premier of Quebec was presented with the car shown in the above picture by admiring friends. Sir Lomer is seen raising his derby in the rear seat of the tonneau, while passing through the streets of Montreal.

ANOTHER AUTOMOBILE FROM INDIANAPOLIS

Indianapolis, July 12—To enter more strongly than ever the field for low-priced cars, the Empire Motor Car Company has been formed by prominent antomobilists of this city, notably A. C. Newby, Carl Fisher, James Allison and Robert Hassler. The concern has already started business in the Rumsey or old Mohawk bicycle works at West Twenty-ninth street and the canal, and the first two cars are expected to be finished early in August. The present work being done is mainly in arranging the machine shops, and preparing to handle the castings. The car will be marketed under the trade name of Empire, and will sell for $800. It will have a four-cylinder, 3½ by 4 inch motor, selective sliding gear transmission, shaft drive, a wheel base of 96 inches, and will be equipped with 32 by 3½ inch quick detachable tires. The company plans to make 2,000 during the coming year, and will begin an active campaign to establish agencies throughout the country.

Wausau, Wis.—John Fehl has leased the Liederkranz Building and will convert it into an up-to-date garage.

News in General

Rapid Fire Gun Mounted on Packard Three-Ton Truck Chassis

Packard as a Military Car—Foreign governments have been very active building automobiles to carry rapid-fire guns, but a test recently made in Cleveland was the first to be officially made in this country. The automobile used was a Packard three-ton truck, and the gun is said to be the largest automatic gun in the world. It fires three-pound shells at the rate of 100 per minute. Experiments were made with the brakes of the truck set and also with them released. In the first case the truck did not move and no shock was felt by those surrounding the gun on the truck platform. With the brakes released the recoil caused a slight movement of the truck. Lieutenant-Colonel O. W. Lissack, of the ordnance department of the United States Army, and Dr. S. W. McClean, the designer of the gun, were in charge of the tests, assisted by the Standard Automobile Company, the Packard Cleveland agent.

Spare Wheel Comes Handy—The Rambler spare wheel proved its adaptability, as well as usefulness, in an incident during the Crown Point races near Chicago. F. L. Winslow, of Riverside, Ill., was driving to the race in his Rambler, which has already seen two years of service, when one of his front wheels was struck by another car, shearing off all the spokes, and he was left stranded by the roadside. Some time later C. T. Jeffery, the general manager of the Rambler Company, came past in his Model 45 and at once offered his spare wheel. Although it was two inches larger in diameter than the broken wheel, the adjustment was made with little difficulty and Mr. Winslow was able to drive home in his own car.

Meiselbach Stays in Milwaukee—The Meiselbach Mfg. Co., of Milwaukee, Wis., has filed articles of incorporation, with a capital stock of $50,000. The company has been considering removal to Sparta, Wis., or Kilbourn, Wis., but has now decided to continue manufacturing its automobile trucks in its present factory at North Milwaukee. Up to this time the company has built trucks in limited quantities mostly for the home trade, but with the backing of new capital it is expected to make an active entrance in the manufacturing field, with light delivery and commercial vehicles of all kinds, as well as heavy trucks.

E. V. Co. Resumes Operation—The plant of the Electric Vehicle Co. at Hartford, Conn., which since July 1 has been closed to permit the receivers to take an inventory, started up full blast last Monday. H. W. Nuckols, the newly elected general manager and vice-president of the Columbia Motor Car Co., which has taken over the business of the old concern, expressed himself most optimistically of the outcome and assures many refinements in the 1910 output. A good part of the creditors have already been paid a dividend of 20 per cent.

Factory for Vanguard Company—The Vanguard Mfg. Co., of Joliet, Ill., has purchased a tract of land adjacent to two railroad lines at Joliet and is erecting a 60x250 factory building of brick and concrete. The new plant will contain a brass foundry and other conveniences, and the company expects to have one of the most complete accessory manufacturies in the country. The 1910 line will include a new brass-frame windshield called the "Breech-Lock," for which many points of superiority are claimed.

Now the Thermoid Company—The Trenton Rubber Mfg. Co. of Trenton, N. J., has been authorized to change its name to the Thermoid Rubber Company, and will continue to manufacture their brake lining material known as "Thermoid," as well as other automobile goods of rubber. The company recently suffered a fire, but only the old part of the plant was destroyed. However, work is to be started at once on the erection of a new concrete structure.

Harris Oils Score Again—The A. W. Harris Oil Co. has received a telegram from the Chanslor & Lyon Motor Supply Co., its Pacific Coast agent, telling of another victory, this time in the Santa Monica race. The winning Apperson and the Chadwick & Stearns that took second and third places, as well as the Chalmers-Detroit, that won the light car race, all were lubricated with Harris oil.

Palmer-Singer to Have New Plant—The Palmer & Singer Manufacturing Company has filed plans for a new factory in Long Island City. It will be located on the south side of Webster avenue, between Second and Third. The construction will be of brick, three stories high, and cost $100,000.

A New Emergency Tire—A company is being formed in Laporte, Ind., to manufacture an emergency automobile tire of wood, and the necessary capital has been guaranteed. The device is intended to be fastened to the wheel to relieve a punctured tire. It is easily attached and can be manufactured very cheaply.

Factory for Elkhart, Ind.—Elkhart business men are planning a new automobile factory to be financed by local magnates, and it is reported that a building has already been leased. F. A. Howe, formerly superintendent of the Elkhart Motor Car Co., is said to be interested in the new enterprise.

Heinze Company Enlarges Plant—The Heinze Electric Company, of Lowell, Mass., maker of ignition appliances, has just completed an extensive addition to its No. 1 plant, making a welcome increase in its manufacturing facilities.

A. O. Smith Company Plans Enlargement—The A. O. Smith Company, of Milwaukee, manufacturer of automobile frames, has arranged to erect several new shops at a cost of about $500,000.

IN AND ABOUT THE AGENCIES

Maxwell, Chicago—J. I. Handley, district superintendent for the Maxwell-Briscoe Company in Chicago, has stated that contracts have been made for the erection of a branch house at Eighteenth street and Michigan avenue. The structure will be fireproof and thoroughly modern in every particular. Workmen have already started breaking ground, and it is likely that the whole building will be ready for occupancy on October 1. It will be four stories high, 80 by 163 feet in dimensions, and the main floor will be used for garage and salesrooms while the offices will be located upon the upper floors. The size of the building will give room for keeping cars in stock for shipment to outlying towns on rush orders, and for giving a more uniform delivery at all times.

White, Chicago—James E. Plew, who has been manager for several years of the White Company's business, has purchased the entire retail sales business of that concern, and will hereafter conduct it under the name of the "White Garage and Salesrooms." He is negotiating for a large building, the location of which has not been announced, but according to the plans, it will be the largest and best-equipped building for automobile purposes in this country. The White wholesale business will be conducted by W. J. Urquhart, as formerly, and its selling organization considerably strengthened to take care of the 1910 line of steam and gasoline cars.

Darracq, New York City—The exclusive American agency for the Darracq car has been secured by Henry Ducasse & Co., 140 West Forty-second street. According to the terms of the agreement, this company is to handle the Darracq throughout the entire country, not only the regular touring car, but also the taxicab, which has been such a success.

Oldsmobile and Oakland, Cleveland—A. A. Auble, Jr., and Fred Wood, formerly Akron, O., agents for the Oldsmobile, have taken the Cleveland agency for that car and for the Oakland as well, and will have the entire State of Ohio as their territory. "Andy" Auble drove a clean-score Oldsmobile in the Glidden tour last year.

Studebaker, Columbus, O.—A. J. Pray has taken the Studebaker agency for this city and has a garage in course of construction at No. 254-266 North Fourth street, which will be completed about August 1. A full line of both gasoline and electric models will be handled.

Hupmobile, Trenton, N. J.—F. C. Martin, who handles the Mitchell at his garage on East State street, has taken the agency for the Hupmobile for the entire State.

Hudson, Chicago—The Levy & Hipple Motor Co., now acting as agent for the Chalmers-Detroit and the Lozier, has decided to take on the new Hudson roadster.

Velie, Brooklyn—The Empire Garage, at 449 Madison street, has taken the agency for the Velie car, a newcomer in this city.

RECENT BUSINESS CHANGES

Franco-American Taxicabs — The Franco-American Taximeter Company has moved to new quarters at Seventh avenue and Forty-ninth street, New York, and will now take complete charge of its taxicab business, which has hitherto been in the hands of Lavalette & Company as rental agents. The new building contains a garage and repair shops, calculated to care satisfactorily for the fast increasing business. This company now has branches in Boston, Washington (D. C.), Chicago, San Francisco and New Orleans.

Carlyle Johnson Machine Company Moves—Necessity for larger quarters has required the makers of the Johnson friction clutch, the Carlyle Johnson Machine Company, to move to Manchester, Conn., nine miles east of Hartford. The new plant was occupied on July 1.

PERSONAL TRADE MENTION

Benjamin Whittaker has resigned the position of treasurer of J. H. Williams & Company, Brooklyn, makers of drop-forgings, and will now give his entire time to handling the exporting business of this company and others, with headquarters at 17 State street, New York.

Henry H. Hower is the new advertising manager of the F. B. Stearns Motor Co., Cleveland. Mr. Hower has resigned the automobile editorship of the Cleveland *Plain Dealer*, and W. S. Gilbert, formerly of the Cleveland *Leader*, has succeeded to the place.

Carl Kaufman, general manager of the Motor Car Equipment Company, 55 Warren street, New York, sails for Europe July 14. During his two months' stay he will visit foreign manufacturers and arrange for the handling of the latest creations in automobile accessories.

E. Leroy Pelletier has been made assistant general manager of the Studebaker interests and will, of course, make his future headquarters at South Bend, Ind. Mr. Pelletier's energies have been notable in the industry.

R. S. Drummond has taken the sales managership of the Detroit Steel Products Co., Detroit, which reports an unusually heavy demand for its motor car springs and drop forgings.

TAXICAB AND TRANSIT

Cabmen Secure Injunction—The independent cabmen of New York City, through their attorney, G. F. Holbert, have secured a temporary injunction restraining the drivers of the New York Taxicab Co. from picking up fares elsewhere than at their regular stands. The cabmen claim that, although only a small number of the taxicabs are licensed as "free-lances," they all nevertheless take fares wherever they find them, thus illegally injuring the business of the independents.

New Orleans, La.—Following a series of trails by the police department, the Abbott Cycle Company agents for the Studebaker car have delivered the new patrol wagon to the department and it has been put in regular service. The city authorities expressed their satisfaction over the adoption of the motor vehicle, which it has been desired to purchase for some time, but the appropriation therefor was not forthcoming until the last budget was made.

Andalusia, Ala.—Business men of Andalusia are interesting themselves in the proposal to connect their town with Pensacola, Fla., with an automobile line. As it is now it is necessary to make an all-day trip between the two places by rail, stopping over night in going via Florida. If the L. & N. Railroad does not put on a through train it is probable that an automobile passenger and freight line will be established.

Simplex Increases Capital Stock—The Simplex Motor Car Co., of Mishawaka, Ind., has filed articles giving notice of an increase in its capital stock, which in the future is to be $400,000.

RECENT INCORPORATIONS

Auto Parts Company, Chicago—Capital, $50,000. To do a general manufacturing business. Incorporators: B. Symonds, A. Symonds, F. W. Hartsberg.

Hartford Auto Parts Company, Hartford, Conn.—Increased capital from $50,000 to $100,000. Manufacturing automobile parts and specialties.

Northway Motor & Manufacturing Company, Lansing, Mich.—Increased capital from $100,000 to $250,000.

NEW AGENCIES ESTABLISHED

Regal: Roanoke, Va.—Model Garage, J. H. Marsteller, proprietor.

Jackson: Columbus, Ga.—Southern Automobile Company.

Waverley Electric: Houston, Tex.—Mosehart & Kellar.

Great Western: Peru, Ind.—Peru Automobile Company.

FISK ON TIRE TROUBLEITIS

The man who has changed tires in the broiling sun in summer and with half-frozen fingers in winter may be interested in some observations on tire troubleitis by one of the Fisk Rubber Company's experts. This specialist recognizes three forms of the disease, due to (1) poor tires; (2) improper sizes; (3) abuse. For the first the remedy is obvious. As for the second, one should not be afraid of getting too large a tire. It may look clumsy, but this is compensated for by its easier riding qualities. The tire manufacturer is blamed for many things directly caused by abuse of the tire, and the commonest cause is insufficient inflation. The specialist adds a few "don'ts" which may be instructive. They are:

Don't slide your wheels by locking your brakes.

Don't go around corners on two wheels.

Don't let your clutch in too suddenly.

Don't let your tires stand on oily places.

And above all keep your tires well inflated.

This is the sort of advice that cannot be repeated too often, and every autoist should remember.

RECENT PUBLICATIONS

Remy Electric Company, Anderson, Ind.—A most interesting little booklet from a pictorial standpoint, in connection with terse details, has been issued by the Remy Electric Company, describing a trip made with the Remy magneto. On November 3, 1908, A. T. Mosher and Harry Harter left Anderson for the South and they were gone until January, 1909, traveling over 6,000 miles of all kinds of country. They many times had to ford bogs and streams in the Florida everglades and like places, and although the battery on the car was submerged and silenced, they had no trouble with the magneto. It was under water many times and this test is a conclusive one. The pictures in the leather-bound booklet tell a realistic story.

The Auto Draft Company, Lake City, Minn.—For the autoist who runs over sandy or heavy roads, the Auto Draft will fill a long felt want. The device comprises a pair of drums which are attached or detached at will to special collars fitted to the hubs of the driving wheels, a cable and two metal anchor stakes. The drums fasten to the collars by an interrupted screw arrangement, the collars being bolted to the spokes of the wheels by means of clips. A car can be withdrawn from mud by anchoring the cable to the stakes and winding it on the drums attached to the wheels. The catalogue has a number of photographs showing the device in operation on a car in heavy sand.

Winton Sales Managers at Their Recent Convention at the Cleveland Factory

VOL. XXI NEW YORK—THURSDAY, JULY 22, 1909—CHICAGO No. 4

THE AUTOMOBILE

BIG TOUR COVERS THE GOLDEN NORTHWEST

In the Minnesota Wheat Belt.

Arrival at Hotel West, Minneapolis

Lake Minnetonka's Waters Provided a Pleasing Diversion.

MINNEAPOLIS, MINN., July 19—Next comes the second leg of the reliability tour. At exactly eight o'clock the first of the contestants headed southeasterly for Mankato, some 132 miles distant over roads that would quickly deteriorate if much rain fell. Confidently and refreshed with the hospitable two-day stay in this bustling city of the great Northwest the dust-saturated and discolored contenders began the obliteration of the 1,813 remaining miles, happy in the knowledge that 823 of the 2,636 total had been left behind.

'Twas with few losses that the fight was renewed, only two of the thirty having fallen by the wayside since the start from

All the Participants in the Glidden Tour Were Most Hospitably Entertained at the Tonka Bay H

Detroit just one week ago. These crippled ones never expected to be real prize winners, being hopelessly outclassed in horsepower and price. Answering admirably the purposes intended for them, they were at an impossible disadvantage in such a strenuous tour as this sixth annual of the American Automobile Association.

One week's driving found these cars still up and doing and without any demerits:

GLIDDEN

No. 1 Premier (Jay).
No. 2 Premier (Hammond).
No. 4 Marmon (H. Marmon).

No. 105 Chalmers-Detroit (Machesky).
No. 108 Pierce-Arrow (Williams).
No 109 Pierce-Arrow (Schofeld).
No. 114 Lexington (Moore).

DETROIT

No. 51 Simplex (Woods).
No. 52 Chalmers-Detroit (Bemb).
No. 53 Premier (Waltman).

By an exact count five of the 15 running days are over. The daily runs have been covered at an average pace of 30 miles per hour for the class A cars and from that down to 18 miles per hour for the class E cars, which are vehicles selling for less than $999.

Although the tour is one-third over it is not expected that one-third of the total penalties that will be recorded on arrival at Kansas City have been chalked up against the cars. As in previous years, the last few days will be trying ones on many cars. So far the cars have all made a most creditable performance; in fact, much better than was expected when they departed from Detroit.

Of the thirty cars that started on the Glidden-Hower-Detroit tour only nine—scarcely one-third—have suffered penalties in one-third of the test. But two have had troubles among the thirteen Glidden cars, and these have been due to two broken fender irons and a mud apron which struck a waterbreaker, was pressed against the flywheel, and had to be hammered back into place. Not one of these incidents or happenings had any effect on the running of the car, in that the motor and the transmission system were not in any way injured. This is a remarkable performance over roads that have been treacherous in many ways, due to hidden rocks buried in the sand and dust, to bad bridge or culvert approaches, to waterbreakers, and to miles upon miles of long sandy stretches.

The Hower runabout contestants are not faring so well, for of the fourteen that started seven have already received penalties. Fifty per cent. penalized in the first third of the tour is too much even if the runabouts have had to travel on a fast schedule as compared with many of the Glidden entrants. With the Hower candidates the penalties have been more directly connected with important parts of the cars. It was never expected that the Hower cars as a whole would show up so well as their Glidden brothers, for the reason that many are lower-powered and not a few are driven by men who have not had previous experiences in long-distance touring.

So far not a single point has been recorded against the trio of toy tonneauites contending for the Detroit trophy, and it would be a most commendable performance if all three could reach Kansas City with clean road records.

Notable Lack of Serious Mechanical Trouble

A great contrast of the mechanical troubles thus far as compared with previous tours is the entire freedom from spring troubles. There has not yet been recorded a single case of breaking spring leaves. In previous Gliddens in the first few days many cars suffered; but it appears that experience has had a valuable effect on this part of the car, and the makers have seen to it that springs are made adequately strong. Last year had several examples of broken wheels. Wheels are heavier this season. In the majority of cars the I-beam front axle is used and not a single one yet shows any weakness as a result of experiences with waterbreakers. In fact, in looking over the cars each morning as they check out, it is remarkable how spick and span they all appear. The fenders are in place, the bodies not dented, wheels are running true, no odor of burning brakes has

', July 18, After a Two-Hour Boat Ride on the Crystal Waters of Beautiful Lake Minnetonka.

been discovered, and many of the high-priced machines have not taken a drop of water since leaving Detroit. It is remarkable how little work is done on the cars.

It is proper to give great credit to improvements in the cars, but the drivers must not be overlooked. Old veterans such as "Teddy" Dey, Frank Wing, Walter Winchester, Webb Jay, H. Hammond, "Jack" Williams, and Gus Buse, Jr., are taking no chances, because each one sees a possibility of winning the Glidden trophy himself. Last year it was won by a team of three men with three cars, but this year it will be won by one driver and his car. This new phase of the rules gives additional interest, and each driver realizes that it entirely depends upon himself whether he wins or loses and that he cannot be prevented from winning by a team-mate who may have been running in hard luck. This is a big factor in the maintenance of the big clean score sheet.

HOW MINNEAPOLIS EXTENDED A REAL WELCOME

MINNEAPOLIS, MINN., July 19—This half of the "Twin Cities" is fulfilling the promises made to give the Gliddenites one of the finest entertainments on record. Never before this year have the travelers been so feasted and fêted, and with four points en route where special programmes have been arranged, each is striving to outdo the others. Elaborate preparations had been made at the Minneapolis Automobile Club for the two full days spent here, and there has not been a dull moment. From the time the cars appeared at the city limits there were interesting doings.

Dinners, trolley rides, military reviews, boat rides and an automobile parade were features, all of which were enjoyed and appreciated. The mammoth parade held Saturday evening in the center of the city took the top notch for beauty and excellent management. When it was stated by those who have seen similar celebrations in other parts of the country that the one here was the finest, the comparison was not overdrawn, and the tourists will take away with them an excellent impression of the enterprise of the autoists of Minneapolis.

There were 358 cars in line, of which forty were elaborately decorated, and all of the participants flew American, Minneapolis and welcoming flags. The lights of the long line, moving at a rate of about 12 miles per hour, made the down-town streets as light as day, when combined with the brilliant decorations on the buildings and the red flares. Such ingenuity as was displayed in the finishings of the automobiles has probably never been equaled, for all of the handsomest ones were illuminated, and the settings were particularly fine. The first prize, a wicker touring outfit, was won by Miss H. B. Whitted, whose Wilcox car, made in Minneapolis, was arranged with a canopy of fresh cut flowers, intertwined with electric lights. The second prize, a pair of Solar lamps, was won by C. E. Van Duzee, who had his Chalmers-Detroit entirely covered with tufted white material, only the tires showing, with all the occupants dressed in white. For the best decorated car driven by a woman, a cut-glass punch bowl and glasses were presented to Miss Ethel Cosgrove, who had a Maxwell handsomely trimmed with white flowers. The pleasing decoration included a large swan and two storks with all occupants of the car utilizing the numerous electric light bulbs which made the craft so markedly artistic. From the rear projected the stern of a canoe in which sat another young woman dressed in white and holding a paddle studded with small electric lights. A wonderfully beautiful effect was made by the American roadster which competed in the division for cars decorated by the children of the owner. Long and racy, it lent itself readily to the scheme, and was entirely covered with dainty white with purple trimmings, and with purple lights along the sides and rear. In front, on the radiator, was an immense letter "G" in lights, in honor of the Glidden tour. It was driven by John Fawkes, the son of L. H. Fawkes, and the prize was a camera.

To show that trucks can be made veritable fairy-lands was illustrated several times during the evening. The best appearing one was beautiful, indeed, a gorgeous affair, in the center of which a miniature fountain surrounded by greens spouted real

Rose-Decked Wilcox Car, a Leading Prize Winner

water from a little conservatory. This won first prize, a Bowser oil outfit, for the L. S. Donaldson Company, and its driver secured an order for a suit of clothes.

Only one untoward incident occurred, that of a fire to one of the handsome cars, driven by the daughter of C. M. Rawitzer. The red roses caught fire from the lamps, and quick work was necessary on the part of the young women in the machine to escape. It was too badly damaged to continue in line.

Charles J. Glidden, Frank B. Hower and Col. W. W. Brown were the judges. After the parade the Minneapolis *Tribune* served a Dutch luncheon to a number of the tourists. Joined with them were officials of the local club, the State association and newspaper men.

Friday evening, that of the arrival of the contest, was given to the men for rest. In honor of the officials of the tour, the officers of the Minneapolis Automobile Club gave an informal dinner that evening in the West Hotel. Among those present were Col. F. M. Joyce, Minneapolis State Association; H. W. Lowry, president of the Minneapolis Club, and Asa Paine, an ex-president.

Saturday morning the real entertainment began, with an excursion to Mennehaha Falls in chartered trolley cars. The club members had rightly decided that their guests would not appreciate rides to and from this beauty spot in autos. The walk was around the falls, to the ravine at the bottom, and then up on the other side to the cars again. Fort Snelling was next visited, to witness a review in honor of the autoists. There were eight companies of the 28th United States Infantry, a platoon of machine guns, and the 2d squadron of the 4th Cavalry on parade, and they made a beautiful showing. The bronzed veterans have but recently returned from Cuba, and had seen service both there and in the Philippines, so the maneuvers were a treat. The reviewing officer was Lieut. Col. Silas Wolf. Immediately following the review the guests of the day walked across the verdant parade ground to the officers' club, where they were entertained.

In the afternoon a special train took about 400 people, half of them belonging to the caravan, to Savage, Minn., to see a match race between Dan Patch and Minor Heir, the fastest horses in the world. One heat was run in 2:06 1-4, and the horses were seen for a time while warming up, while lesser lights of the stable held the attention during the process.

Sunday the tourists were given still another kind of an outing. At 9 o'clock several score of automoiles were brought to headquarters by their owners, and all the Gliddenites in sight were taken out to beautiful Lake Minnetonka for a two-hour ride. Dinner was taken at the Tonka Bay Hotel, and once more the cars were pressed into service to convey the guests to the Automobile Country Club for a buffet supper. The club has a superb location, and 'tis doubtful if any other automobile organization is so ideally situated.

As the Illuminated Parade Progressed Through the Streets of Minneapolis, the Sight Was Inspiring to the Beholder

The Last Day of the Tour—When Dai Lewis made the pathfinding trip he took six days to cover the 154-mile route between Madison and La Crosse which the tourists were required to cover in 8 hours and 42 minutes. "I admire your nerve in coming in on the hour," said one driver, "after having laid out that route. I certainly would never have taken the same chances, now you may depend upon that. All that saved your life was the fact that it did not rain." Lewis smiled, and his reply was disquieting. "You think La Crosse to Madison tough? Just wait until the last day of the tour. Then you will see something." On that basis those who have lost points have failed to worry, as they believe that they will have plenty of good company before the tour ends, especially if rain should set in and stir up the roads, converting them into a muddy paste that will be hard to drive straight on.

HOW TOUR PROGRESSED FROM CHICAGO TO FORT DODGE

ENTHUSIASM marked the progress of the tourists through the States of Wisconsin, Minnesota, and part of Iowa. Not only was the tour made welcome, but the rural population turned out *en masse* to watch the cars pass and to speed them on their way. The roads showed a vast improvement over those just traversed in Indiana and Illinois, which, with the enthusiastic reception accorded by the people, made the going more enjoyable for the contestants themselves and the numerous newspaper men. The only thought that spoiled the enjoyment was of the conditions to be met with farther on, which Dai Lewis felt free to state was much worse than anything heretofore. With this in mind, the drivers exercised much care.

THIRD DAY—CHICAGO TO MADISON, WIS.

175.2 Miles

MADISON, WIS., July 14—There was some keen enjoyment in the run here from Chicago. Furthermore, the escape from the so-called "Windy City" lay through its most beautiful sections, including the Lake Shore drive, Lincoln Park, and then Sheridan road. Surely the man who labors during the day in the murky and disheveled town must appreciate lovely Evanston when he arrives home at night; and Kenilworth, Glencoe, Highland Park, and other succeeding places located on the shores of Lake Michigan are similarly inviting. A look at Zion City gave one the idea that it no longer had the directing hand of a capable manager, for, despite his peculiarities, Dowie possessed rare business ability.

Kenosha, home of the big Rambler plant, and also noted in automobiling for the Solar lamps of the Badger company, figured as the first city entered in Wisconsin. While there were no Ramblers in the tour, one of the notables met in the main street was Thomas B. Jeffery, in a runabout driven by his son, and that the veteran maker, first of bicycles and then automobiles, was interested in a look at the dirt-daubed cavalcade required only a hello to the man who refused to become involved in the Selden litigation.

Mitchells were numerous in Racine, though few of the company's officers apparently took time to see the Gliddenities. Sales Manager Gilson had seen the start at Detroit, and admitted that this year the long route had no charms for him. He and Al Reeves, however, watched the cars fly into the outskirts of the town. The KisselKar plant being located at Hartford, it was natural that cars of this make in demonstration form were to be observed in the vicinity of Milwaukee.

Prompt and generous hospitality came to the tour party during its Milwaukee stop, the refreshments including all the beers that have "made Milwaukee famous." The officers of the Milwaukee Automobile Club saw to it that everything was done that "Jim" Drought has mentioned the night before in Chicago, for he was "taking a day off" by riding in the Premier pacemaker of "Napoleon" Hower.

Wisconsin supplied roads that proved an appreciated inprovement over the alleged highways of Michigan and Illinois, and, excepting a stretch of about 15 miles between Waterloo and Watertown, the going bothered the contestants slightly, though Madison certainly presented an inviting appearance when reached late in the afternoon. Here is located the University of Wisconsin, and it is not boasting for the Badgerites to say that their institution of learning has the most advantageous and picturesque site of any college in the whole country. Lake Mendota is a lovely sheet of water, and its sister lakes are scarcely less beautiful. Though no set form of entertainment was provided, many of the party were shown the beauties of the model little city, Glidden, the globe-girdler, arousing pardonable local pride by comparing it to Athens, which was not very far-fetched for a good illustration. The Governor was absent, but Colonel Munson, his private secretary, assisted the officers of the Madison

Veteran "Teddy" Day, Who Again Pilots a Pierce

Automobile Club in the courtesies showered. It followed as a natural sequence that "Jim" Drought had a hand in the proceedings.

Two Cars Met with Penalization—Rough as some sections of the route were, and as fast as was the time made when the fine roads presented themselves, the Gliddeenites had no perceptible trouble, and not a single penalty was inflicted in the ranks of the Glidden or Detroit trophy cars. There were two among the runabouts which felt the pen of the scorer, however, and one of these felt something still harder. This was the little McIntyre high-wheeler which jumped down an embankment before reaching Milwaukee and there remained. Its driver, Frank Goodwin, later stated that his car got caught in the tracks of a trolley line. When it did jump out and extricate itself a nut on the steering system dropped off, and the car was ditched and damaged beyond immediate repair. Neither driver nor observer were injured. It was not expected that the McIntyre would go very far without penalization, for the required speed was too great, but it was hoped that it would make a fine showing for the motor-buggy industry. On the first day it was 29 minutes late, and on the second this was increased by 423.7 points, so that its total, when the 1,000 for withdrawing was added, arose to 1,452.7, a penalty incommensurable with its trouble. The sturdy little Brush runabouts are in for endurance, and it is not expected that they will keep the time schedule. Consequently it is understood that the entrants intend to continue just to demonstrate their ability to cover the distance at a pace suited to their size and power. The one driven by Huss was the other of the two machines penalized to-day.

The running time for the 175.2 miles was 8 hours 50 minutes, an average of 20 miles an hour being required of the class A cars, those selling for $3,750 and upward, and, as usual, a proportionately lower rate for the smaller machines.

Charles Goldthwaite, Who Drives the Maxwell Runabout

FOURTH DAY—MADISON TO LA CROSSE

154.4 Miles

La Crosse, Wis., July 15—One could easily have imagined himself in Vermont to-day, for the country bore a striking resemblance to the Green Mountain State. Leaving Madison, the little gem of a city, and taking a parting view of its quartette of lakes, the Wisconsin river was crossed at Sauk City, just below which is Prairie du Sac, the two dwelling in peace and harmony and advertising their advantages jointly.

Baraboo is an enterprising and substantial town which deserves to have its name writ large for the reading of automobilists. With its own money, and no help from the State, it has constructed miles of good roads in its vicinity. As the flying procession passed through Baraboo's well kept streets there was a shout of welcome that had the genuine tone in it; and this same kind of greeting seldom had a dissenting voice all the way to this lively burg grandly located on the Mississippi. Reedsburg, however, particularly warned the travelers not to go faster than 12 miles an hour, but, with the exception of a short stretch of brick pavement through the main street, this was plenty fast enough.

Once the route led for several miles on a crossroad that divided fields of grain. The explanation of this sandy substitute for a road came from Pathfinder Lewis, who said that when he laid out the tour in the Spring the main road was impassible and someone directed him to this little used sand track. At any rate it contributed something to the diversified character of the day's running, which presented much to please the eye even if it included road surfaces of changeful moods. For the first time in the tour one met with and cussed the waterbreaks that infest Pennsylvania mountain roads.

Between Kendall and Sparta three ridges were climbed and descended, which caused distress to nearly every car in the tour. The presence of waterbreaks added to the task, and all uttered words of thankfulness when gliding into hospitable Sparta, the automobile club of which tossed lunches and drinkables into the laps of the car occupants. The remaining 25 miles of the journey had no incidents worthy of note, though mention should be made of the fact that there was some "beating" to keep free from time penalties.

To a number a pleasant feature to-day happened just beyond Wilton. After climbing a long hill two of the press cars and the Jewell roadster came upon a Pierce-Arrow picnic party. The photographers stopped a moment to take a picture, and in the meantime the hungry men discovered what they voted was the best cake in the State of Wisconsin. The car belonged to La Monte Rollands of Tomah, and with him were W. R. McCall and L. M. Compton, and party of ladies.

How the Contestants Progressed—A single penalization was inflicted in the Glidden ranks, and it was for work of little consequence. The Midland, driven by E. O. Hayes, in crossing one of the terrible waterbreaks in the semi-mountains, scraped its dustpan upon the ground. To straighten this required 15 minutes of work, thus giving the car a demerit of 1.5 points. Shortly after this the left front fender broke loose, and wire and strap were procured with which to fasten it. The cost of the material was 30 cents, for which the penalty was .6—double the one-tenth system because the material was purchased. It took 16 minutes to fix this, so that the total penalty against the car is 3.7 points.

The Detroit trophy trio kept their ranks intact.

Howerites were far less fortunate, for penalties were inflicted upon five of them, four of whom had previous clean bills of health. The lowest was that of the Mason, driven by Roy Snyder, which was given 2.4 points, divided into 2.2 for labor in changing a petcock from the radiator to a cylinder head, and in plugging up the vacancy in the radiator. For the wooden plug used in the latter instance the charge was .2. The Maxwell. driven by Goldthwaite, took slightly more—2.6 points. A spring clip on this machine gave way yesterday, and the crew was undecided as to whether to use a new one or not, for the car

might have traveled without it. The rough roads to-day were sufficient to show that no risks should be taken, and so W. F. Smith, the Maxwell manager, instructed Goldthwaite to put in a new one. For the clip the damage was .4, and for the labor it was 2.2.

The rules this year might confuse those not intimately familiar with them in certain points, as illustrated by the case of the Maxwell. The clip cost 20 cents, or, at least, over 10; but, inasmuch as it was not carried at first, the score was doubled and, as the 11 minutes spent in adjusting it were upon such an article, the time was marked up double.

The Jewell roadster, driven by John Shimp, was nine minutes late—its first penalty.

Two other cars whose records were touched did not fare so easily. These were the Hupmobile and the Brush, driven by Huss. The former had been able to maintain the hard schedule on the roads of the first three days with little trouble, but the precipitous hills of to-day were too much for the little car, and it was marked 358 points for lateness. Its companion in trouble was another of the little fleet, which found the grades very steep for a one-lunger when combined with time necessary for certain adjustments. Two connecting rod bearings were used, and in all the material and labor counted for only 8.9 points, with 335 points charged for tardiness, so that its score was increased to a total for four days of 957.6.

The other cars were all classes and had no difficulty in negotiating the route, although a number of them steamed on the heavy climbs. The conservative methods of driving were less in evidence, perhaps because time had to be made up whenever possible. Considerable tire trouble was noticed.

FIFTH DAY—LA CROSSE TO MINNEAPOLIS

177.8 Miles

MINNEAPOLIS, MINN., July 16—Pleasant valley to-day elicited the encomiums of the lovers of scenery, and one would have to go a long distance to find its superior in quiet beauty in this big land of ours. Dai Lewis had incidentally mentioned the existence of this valley, but few were prepared to enjoy such a gorgeous prospect of nature as was discovered some 25 miles from La Crosse. Next came the Stockton valley, with additional loveliness in the way of foliage-bedecked hills that closely approached mountains in size, and again followed a reminiscence of the Green Mountains and the Berkshires of Massachusetts.

Emerging from the hills, the miles of grain fields stretched in all directions, and then one began to understand the source of the real wealth of the Northwest. Signs of prosperity abounded in the waving seas of wheat. and oats, and corn, and the farmers gazed at the motor-driven brigade with friendly eyes, and their greetings bore tokens of unmistakable friendship. For the man on a Minnesota farm there could be no greater boon than the automobile; furthermore, he is appreciating the fact by buying cars, as was made apparent again and again at the crossroads gatherings where invariably there were one or more autos to be seen.

Lewiston, Utica, St. Charles, Dover, Eyota, Chester, Rochester, Orinoco, Pine Island, Zumbrota, Cannon Falls and Hampton were among the flourishing communities passed through on the way to St. Paul, which is only 10 miles from its sister city, though one is constrained to note the absence of very much sisterly affection.

It was a triumphal progress that punctuated the tour's arrival in Minneapolis, after being met in the outskirts by a delegation from the local automobile club, which included President Lowrie and other officers. President F. M. Joyce, of the Minnesota State Automobile Association, to-day came with the tour on its 177-mile run, and there seems to be no hesitancy whatever on the part of anyone to give full credit to him for the excellent condition of automobile affairs in the State.

Penalizations Were Few—When the route of the tour was first spoken of the officials stated that there would not be a perfect score, and when Pathfinder Lewis returned from his prospecting with long tales of the road conditions the contention was believed. There are those among the tourists to-day, however, who are thinking that this must apply to the country beyond. At any rate the 13 Glidden cars and the three Detroit trophy ones performed as usual without a smirch on their records.

There were three inflictions among the roadsters and runabouts, but no new ones, and one of these was a withdrawal. The Jewell added 6 points to its 9 of yesterday, giving it a total of 15. The items were as follows: For outside labor in rethreading a gasoline force feed pump, 3.8 points; for labor of the driver upon this, 1 point; for a hinge which cost 5 cents, .2 points; and for applying the hinge, 1 point.

The withdrawal was that of the Hupmobile, which stripped a low-gear pinion in the transmission in trying to climb the steep hills at the beginning of the journey. When this happened it was only a few miles from the start, and the car was able to get back without difficulty and obtain a new one. It is understood that the car will continue as a non-contestant. The Brush naturally contributed to its increasing total, the 294 points giving a total of 1,251.6. Of that to-day 285 was for lateness and 9 for labor. The score of the other Brush was given out this evening as incomplete because in coming into this city Trinkle went according to the route book to the Plaza Hotel instead of following a change to the West Hotel. It is probable that his application for an allowance, inasmuch as he waited after arriving at the Plaza, will be granted and his story is substantiated by the observer.

SIXTH DAY—MINNEAPOLIS TO MANKATO

132.0 Miles

Mankota, Minn., July 19—When Dai Lewis laid out the route of the tour in the Spring one of the toughest stretches that he encountered was between Minneapolis and this city. A good part of the way consisted of what are known in this country as "gumbo" roads, which in the rainy season are well-nigh impassable. Even with a hard downpour of a day the going is exceedingly difficult, and it was for this reason that the run to-day was made of only 132 miles, coupled with the additional fact that the next big town where hotel accommodations were procurable was too far away.

With fond recollections and thorough appreciation of the good time supplied by the Minneapolis club, the contesting part of the tour took its departure from the front of the Plaza Hotel at 8 o'clock. The trip here owing to the favoring weather conditions proved easily within the capacity of all of the cars. Of hills there were none worthy of the name, and the scenery had almost exclusively the look of the fields, seas of grain frequently encompassing the horizon on all sides. St. Paul waylaid the tour shortly after it left the rival sister city, and the cars were deviated from the street and into the big auditorium, where into the laps of the occupants were thrown cigars and candy and other souvenirs of the city, including a miniature of St. Paul himself.

Northfield, some fifty miles from Minneapolis, attracted attention because of the fact that it was here on September 7, 1877, that Jesse James and his gang met with their first Waterloo, two of the gang biting the dust, though two townsmen were also killed in repelling the attempt to rob the bank.

Enthusiastic welcomes pleased the tourists until one got tired of waving answers to the flag and handkerchief and other salutes which punctuated progress through every town and village, with equal enthusiasm, though necessarily intermittent, in the country.

A Big Tent Filled with Refreshments Was Provided for the Hungry Tourists by the Milwaukee Automobile Club

Owatonna contributed the noonday luncheon, its automobile association doing the honors, with wives and daughters of members serving the refreshments, which included the best buttermilk ever tasted. Owatonna is the biggest town in Steel county, which annually produces about three million pounds of butter and holds the national championship in the quality of its dairy achievements. The president of the local club is Senator T. H. Cashman and the secretary is Dr. A. B. Stewart. In the absence of the president, G. A. Merrill directed affairs in a most satisfactory manner.

Of course to-day some more of the three thousand odd lakes in Minnesota were sprinkled through the country traversed, and several possessed uncommon beauty, Elysian lake probably carrying off the honors.

Mankato with its solitary big hotel had some difficulty in housing the party, some of whom passed the night in homes of residents who volunteered to meet the needs of the overflow.

To-morrow night at Fort Dodge, Ia., will begin the ten days' occupation of Pullman sleepers, and it must be confessed that the prospect is not viewed with any vast amount of enthusiasm.

Webb Jay in Premier Checking Out at Minneapolis

To-night Globe-Girdler Glidden announced that if next year's tour is a San Francisco-New York affair he will drive a car himself in the non-contesting division.

The local club is supplying entertainment to-night to the visitors, a band concert, ride on the Minnesota river, and a Dutch lunch being included in the festivities. The journey to-day having been so easily accomplished, the recipients of the courtesies are in mood to enjoy the occasion.

Penalties Inflicted on the Sixth Day

The cars to-night are parked on a historic and bloody spot. On the day after Christmas, in 1862, thirty-eight belligerent Sioux Indians were captured by the United States troops and strung up on the very half-acre where the cars now stand shrouded in their tarpaulins.

All the machines seem to be in splendid order, and little change was made in the standings to-day. Only one Gliddenite had to suffer, and that was the Chalmers-Detroit, driven by William Bolger, which had to tighten a loose fender iron which has been giving trouble for some time. There was more alteration in the standing of the Hower trophy contestants. The Jewell roadster, in charge of John Shimp, spent so long tightening hub flange bolts this morning that 5.6 points were chalked up against it, with an extra 0.2 point for a washer used. The total of this car has therefore grown to 20.8 points. The Mason's score has been increased from 2.4 to 4.3 points, on account of some work done on the run from Madison to Lacrosse last Thursday. The 1.9 difference is the price of making a wooden plug for the bottom of the radiator to replace a petcock transferred to the cylinder head. The repair was so complicated that the committee has only just decided the penalty.

The two little Brushes have been withdrawn, the entrant stating that the schedule has been found entirely too strenuous for a 7-horsepower, single-cylinder runabout. The marks given them on the runs from Madison to Lacrosse and from Lacrosse to Minneapolis have just been announced. On the former, the mark was 3.0 points, being 0.6 for a new radius rod and 2.4 for the labor of putting it in place. On the following day another radius rod had to be used, but only eight minutes were spent putting it in place, so that this penalization was 1.6 points, making a total for the little car of 5.2. Dwight Huss, too, had considerable trouble, as expected. Both cars, of course, get the maximum penalty of 1000 points for their withdrawal. However, they will continue with the tour as non-contestants.

J. A. Wicks in Moline Car Near Pine Island, Minn.

The little Hupmobile arrived this evening and was given a warm reception by the crowd. It is now being driven by A. E. Nelson, the designer, in place of Frank Striman. Two of the non-contesting cars met with mishaps during the day's run. The second pilot car, used in following up Dai Lewis and in further distributing confetti, was nearing Faribault on the sun-baked gumbo roads when the right steering knuckle gave way, and the car had to stop on the border of a cornfield. Mortimer Reeves, with his bag of "scent," was taken on in Chairman Hower's pacemaker. The driver took the broken knuckle into Faribault and had it welded at the local smithy's. The car arrived late in the evening.

The Maxwell, carrying a number of Chicago newspaper scribes, reported with a bent front axle, the bend coming between the spring seat and the right wheel. The accident was in no way the fault of the car. It happened while turning from the road to allow one of the Pierce roadsters to pass. This courtesy is granted by all non-contestants to the real tourists, but the reward of virtue in this case was that the wheel dropped into a hole so large that it nearly disappeared from sight. The axle was straightened this evening, although the mishap did not prevent the car from coming into the city easily.

Strange to relate, tire troubles were numerous, due possibly to the fact that the pneumatics are beginning to feel the strain of the thousand miles that have already been put behind. Then, too, the speed was greater than usual, and at the same time there were numbers of right-angled turns. None fell behind the schedule because of punctures or blow-outs, but not a few had their innings along the roadside in the 132 miles.

SEVENTH DAY—MANKATO TO FORT DODGE

138.6 Miles

Fort Dodge, Ia., July 20—Down into Iowa to-day straggled the goggled-eyed caravan, with the same interminable line of roadside onlookers waving and shouting greetings, and at two places contributing to the demands of the inner man. The route was almost due south, and the gumbo brand of road continued its rough, though dustless, course into Iowa, the line being crossed just outside of Elmore, where the townsfolk supplied buttermilk in generous quantities. Occasionally the gumbo had been dragged, but more frequently its roughness compelled a speed of not more than twelve miles an hour. Algona, 93 miles from Mankato —thanks to the liberality of E. E. Connors—supplied luncheon and some drinkables, though the town is "dry."

Soon afterwards a sign across the road indicated the county line of Humboldt County, and for some twenty-five miles the going proved most enjoyable. Then there came an abrupt return to the gumbo, continuing almost into Fort Dodge. The town today is agog with the Barnum & Bailey circus and filled to overflowing. However, many must have put off the show till tonight, as the streets were alive with people when the cars began to arrive in the public square. The reasonable schedule for the 138 miles had in view the possible effects of rain on the gumbo, and as there was no waterfall, the tourists could take things quite easily. The weather to-day has been scorching hot, but a breeze saved the tourists from feeling its full effects. In Fort Dodge the thermometer showed 115 degrees in the sun and 95 degrees in the shade, and it is said that a hotter day has not been experienced in years. The party is finding sleeping cars a bit uncomfortable to-night.

E. L. Ferguson had a narrow escape from serious injury to-day. His Acme hit a culvert near Eagle Grove, Ia., and the car and its occupants were thrown through a barbed-wire fence into an adjacent corn-field. In trying to save himself Ferguson caught hold of a strand of the wire, which slipping tore long gashes in his hand and broke several of the small bones. The injuries were dressed by a local surgeon. Ferguson caught the special Pullman train on its way here. He will continue the tour, but *a la* Pullman instead of Acme.

Although the cars to-day at times had exciting escapades, and three of them learned that Iowa roads are not always what they seem, penalizations were few. The Maxwell roadster, driven by Goldthwaite, received 1.6 points for labor in stopping a leak around a cylinder valve cage. The Midland got 0.6 points for tightening a fender iron. The Chalmers-Detroit stopped to tighten a connecting ord bearing, for which it received 17 points, plus 187 points for the ensuing lateness.

During the day the Mason Hower contestant pulled to one side to allow another car to pass, and as reward for its politeness its wheels sank immediately into the gumbo so that it could not get out under its own power. The Midland, which is running under the Glidden flag, was the next along and it was successful in landing the Mason and its crew on firmer ground. The other cars to get in trouble were of the non-contesting division. The Rapid truck, which seems to be followed by a specially active hoodoo, turned out for a hay wagon just outside of Algona, and immediately slid off the road into the ditch. It was rescued by a couple of the other cars without suffering any injury. The Maxwell press car ran out of gasoline and was pushed to one side to allow one of the Chalmers-Detroit cars to pass. It also sank into the gumbo so that outside aid became necessary. H. C. Marmon gave some help, but his time was necessarily limited and he had to go on. Finally man's best friend, so alleged, the horse, was pressed into service for the first time on the trip. The Studebaker-E. M. F. car which was delayed yesterday had more serious trouble this morning. The left half of the drive axle crystallized and gave way at Vernon Center, only 21 miles from Mankato.

The machines which received penalties as a result of to-day's trip had all lost their clean records previously. To-morrow there will be some tough hills in the 185 miles to Council Bluffs and the predictions are many that the scores will be changed by nightfall. Rain has fallen recently in the roads to be traversed within the next few days and the roads are reported to have suffered severely.

Replenishing the White Steamer with Kerosene

A FEW OBSERVATIONS MADE EN ROUTE

In These Long Tours it has come to be business pure and simple, and no horse play. One man, and he was a maker, gave it out cold to his men that things of late had changed and that all horse play, late hours, and cutting up would have to be dispensed with." I am not out for the fun of spending a few thousands of dollars for my firm just to let some men have a good time," said this man. "My men are out to win the trophy, and they are going to start every morning in shape to make a hard drive. Horse play is all right in its place, but the time for such doings is not on a tour when results count for so much."

Hats Are Various and Many in style on the trip. Every time a hat store on the line offers anything outlandish in the way of a chapeau the tourists go right after the novelty and buy out the dealer. Lots are not large in the way of bargains that are wearable, and so the great variety. Khaki, however, as a touring uniform has come to be quite the style, and nine-tenths of the tourists wear suits that seldom cost more than $5. Although cheap, the suits look well, and the men appear to better advantage than in dusty business clothes.

The Underwood Typewriter Company supplies typewriters at many of the points on the route, and these machines are placed in press headquarters, much to the delight of the press men.

HEARD AND SEEN ALONG THE ROUTE OF THE TOUR

How Moline Squadron Travels—While the regulations allow each car to carry a sack of extra parts for replacement in case of a breakdown, the three Molines which constitute the "Moline Dreadnaught Squadron," are traveling without a single piece of additional equipment. The Molines are the only cars which are not equipped with a bag full of extra parts. When asked why he was taking this unnecessary chance, President W. H. Van Dervoort said: "When an owner starts on a tour he is not equipped with extra parts. The Glidden tour is to demonstrate what the motor car can do under regular touring conditions, and we are endeavoring to demonstrate that Molines can travel 2,600 miles without replacements of any sort. Our perfect scores bear us out in this respect. Personally, I would like to see the extra parts eliminated from the rules." Too bad this very commendable attitude is not taken by all contestants.

"Jehosaphat, Boys! It's a Scarecrow!" said F. Ed. Spooner, just outside of Union Center, Wis., after members of the party in the No. 89 Studebaker press car had waved their arms off at a lady (?) in the field who was apparently busy with hoeing and had just raised up to watch the autos go by. The tourists like to receive recognition from the people along the route and upon finding a "frozen face" always try to make her smile or wave her hand, and then say "Thank you." This particular lady, well dressed and to all appearances good looking, would not show the slightest sign of recognition, and the Studebaker slowed up to try and make her do so, the men rising up in the car to do homage to her beauty. The discovery that she was a scarecrow quite unnerved them, and after that they were not so enthusiastic in trying to make anyone wave.

An Observer on the Brush did not know that the speedometer of the little car was out of order. He watched it closely and noted that it registered 55 miles an hour regularly. "Say," said he, "we'll just about be up to the big fellows before long, won't we?" Another observer who made the trip in the little Brush said: "I tell you that I had about the most remarkable ride I ever took. I would never miss one ride of the kind for the world; but never again. I've had my time of it. Why, Tinkle just opened the little car wide, and then held it right down to hard tacks regardless of the road conditions. We went over the bumps at full speed, and we flew, or it seemed to me we did. And with that sort of work the little car held together, and we arrived on schedule time by a narrow miss only."

The White Steamer Quartette—A quartette has been organized by the crew of the White Steamer, the car which is making a highly successful demonstration of the use of kerosene as fuel. As might be expected, the vocal efforts of the quartette are devoted mainly to exploiting their use of the new fuel. On entering each town they attract attention and applause by rendering the following song to the tune of "No Wedding Bells for Me":

No gasoline for me,
It's as dear as it can be.
  Kerosene is what we're using.
  Old John D. is surely losing.
Three cheers for kerosene,
  No gasoline for me.

"'Tain't No Race, Then!" said one farmer. "Then I don't see why we folks are so interested, by Gol. We came a darned long way to see this 'ere race only to find that it ain't a race at all. I'm plumb disgusted with myself, for my hay's laying there, and, by Gol, I believe it's going to rain. As long as 'tain't no race I don't suppose you people 'll care, for you can get in any old time." Informed that to get in ahead of time was as expensive in the contest as to get in behind time, he scratched his head. "You call it a contest, by gosh, and then you say it ain't a race; and ain't a race a contest—that's what I want to know." Time was precious, so the gentleman from rural Wisconsin was left still puzzled about a race that wasn't a race.

"I Find the People Very Cold and distant when going through the towns early in the morning," said Chairman Hower, "but I understand from those who bring up the rearguard and try to keep out of the dust that the people have warmed up toward the last and throw flowers, kisses, and all sorts of bows and smiles at the tourists. I presume that I start the training of the masses, and others who follow are quite as good teachers." The chairman was right, for those who trail are the men who have the real fun and who lose the monotony of the journey through the reception accorded all along the line. Perhaps the chairman thinks that people who get up early ought to be good natured.

In Days of Old "When Knights Were Bold" the tourists ofttimes heard disquieting reports of obstructions on the roadways to be followed and scout cars were sent out to clear the way. There was antagonism in those days against the tourists. All that has changed now and farmers make Glidden Tour Day a holiday, bring their family and friends and hold a picnic by the roadside, cheering the contestants on. In days of old speed traps were set to catch the tourists, but to-day the policemen in all of the towns en route push the tourists on and give them a cheer for every ounce of speed they put on.

Things Have Changed within a very few years. All antagonism has apparently disappeared and farmers cheer the tourists lustily and wave to them to go faster. The automobile has come to stay, and its beneficial effect has been noted by the farmer, who is not unappreciative of the good roads movement now so successfully launched. The farmers own automobiles, and want good roads, and know that the autoists of the entire country also want them, and are working tooth and nail to benefit the farmer as well as themselves. Conditions will improve more and more as the years go by.

Charles J. Glidden Predicted at Minneapolis that within five years the men who kick about the roads and the stiff schedules will be looking from above on the roads they once cussed and laughing at the old days, just as the cyclists look backward to hard centuries and double centuries made on roads even worse. "Many of these men will be in the aero field," said Mr. Glidden, "and I have no doubt that endurance contests in the future will follow much the lines of our great tours of to-day, but without thought of roads. It is not impossible in fact, it is certain."

More News Matter is being sent out from this tour than any other. C. H. Kent, representative of the Western Union, who is making the tour in a Chalmers-Detroit car, says that an average of about 30,000 words is being sent out by his company alone, and P. S. Williams, of the Postal Company, says his company is doing fully as well. It is not improbable that an average of 60,000 words daily for the trip would be about fair, and this will be greatly increased providing the weather changes and the difficulties become greater.

Tonneau Is a Catch-All—To the driver, the tonneau of a car is a catch-all and the convenience of his passengers does not enter into his mind. "Put it into the tonneau" is his regular statement and his regular habit, and those who have to travel in the back seat suffer hour after hour through inability to get their feet to the floor or to get them into a comfortable position. The observers on the tour objected to this feature of touring, and Chairman Hower, at one of the early meetings, asked that the drivers of the cars cease choking up the tonneaus.

Talk of the "Transcontinental Tour" is heard on every side in the touring party. Charles J. Glidden said in speaking of it: "I have talked the matter over with Mr. Hower, who is now in favor of the tour to start from San Francisco and finish in New York. The rules will be more liberal than they are at present, and I believe that the entry list will be a large one. The makers seem to want a really hard trip, and an across-country trip would be a splendid chance to bring out a record breaking list."

"Matches That Won't Blow Out," handed out by Morgan & Wright, are also the matches that set the world on fire, for the occupants of tour cars touch them to cigars or cigarettes and then throw them carelessly to one side. Sundry fires along the roadside have been caused by this, and No. 79 Studebaker, driven by George Smithson, and No. 83 Chalmers, driven by Harry Ford, stopped to relieve the anxiety of one woman near El Roy by putting out what might have been a serious fire for her.

Photographers Are Having a Hard Time on the trip, for the reason that the promoters failed to take them into consideration by routing the tour westward rather than eastward. Somehow the sun has been directly against the men who push the button at most of the interesting points on the route, and as a consequence the pictures of this journey have not been altogether up to the usual standard set by those who make it a business to photograph every tour.

starters and their numbers pasted on cards have been checked again and again.

Dogs Were Chained as a Rule all along the route through Wisconsin, and many a good dog was saved to posterity by this fact. Chickens have taken wisdom with age, and few chickens are caught crossing the road. The youngsters of a few years ago were frequently orphaned by the autos and grew to know that it was dangerous to cross the road as was their custom in years gone by.

When the Panoram Was Taken at Lake Minnetonka one man of more than average intelligence sat at one end of the line when the circuit panoram started and then ran around back of the camera and took a position at the other end of the line, appearing twice in the same picture. It is not on record that he ordered any more pictures than the man who appeared only once.

"Johnnie" Johnson, old-time "King of the Cyclists," became very much excited at Minneapolis, where he is manager of the Winton branch, when his employees did some great decorating for the parade, in which the six-cylinder Winton made a hit. "Johnnie" was a member of the reception and entertainment committee and did yeoman work.

Before Reaching Minneapolis the Route Passed Through Beautiful Pleasant Valley, One of the Gem Farming Regions of Minnesota

Youngest Driver in the Tour—Considerable interest is centered in the driving of W. S. Gregory, driver of the Mobile No. 102, due to the fact that he is the youngest driver in the tour. Gregory is only eighteen years of age, but is handling his big car like a veteran, and has already received compliments from many of the tourists. Gregory hails from Los Angeles, Cal., and came East purposely to drive in the great American touring classic.

H. C. Marmon and F. E. Wing drive the two Marmon entries with tops up, and attract no little publicity to themselves by so doing. As a rule every car is stripped right down to action for the tour, and tops are put away until after the finish, owing to the trouble they cause. In these long, hard rides the hundred-pound top hanging at the back throws a hard strain on the body, and a competitor cannot afford to take the chances.

Rural Free Delivery has aided in putting the farmer in closer touch with the motorist, and the increased interest shown along the line has been very marked. The farmers and their families have been seen standing at the roadsides studying the daily papers carefully every time a car passed. The lists of

H. O. Smith, of the Premier Company, Indianapolis, was forced to leave the tourists at Minneapolis to go home to do a little work, but will again rejoin the party at Council Bluffs. Mr. Smith is enamored of the big tour, and has become a veteran by reason of his steady attendance in the past.

The Rapid truck is now starting at midnight in order that it may save delay on the road turning out for the tourists, as it does whenever a car comes in sight. The truck came through successfully from Madison to La Crosse and feels certain now of a successful trip to the finish.

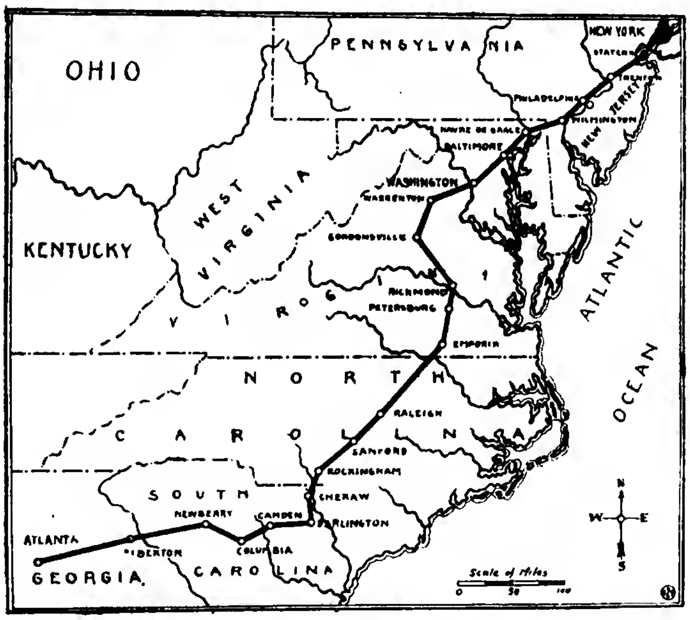
J. M. Evans, representing the Brush in the capacity of advertising representative, feels that his subject is a good one, as the little Brush cars with but 7 horsepower are performing miracles, considering the odds accepted in participating in such a strenuous tour.

NORTHERN TRIP OF THE GOOD ROADS SCOUT

By PATHFINDER

SEVERAL weeks ago a brief description of the trip of the New York *Herald's* White Steamer from New York to Atlanta appeared in these columns. After a week spent in the latter city, the car started northward, this time over what is known as the "capital-to-capital" route via Elberton, Columbia, Raleigh, Richmond and Washington, as shown on the accompanying map. Although no official announcement has been made, it is understood that this route was found to be, at the present time, not nearly as good as the route via the Shenandoah Valley, Danville, Charlotte and Anderson which the White covered on its trip southward.

As was anticipated by those who have had experience in southern touring, the "capital-to-capital" route, being comparatively near the coast, leads through many miles of sandy, swampy country with almost innumerable creeks which are not provided with bridges. But it was not all bad going by any means, and the scouts reported a number of localities where the roads were almost faultless.



"Capital-to-Capital" Route—Atlanta to Washington

Not in many years has the South been so stirred up as it is by this good roads project. The scouting trips have awakened a spirit of emulation so that each county is striving to excel its neighbor in good roads development and an appeal has been made to local pride, the results of which will be far reaching. The business men in the various cities are alive to the advantages which would result from having the "New York-Atlanta Highway" pass through their sections and, accordingly, each day the scouts learned of road improvements which were projected and, in many instances, work was actually started while the White was on its way northward.

Foremost among the good roads advocates of the South is Leonard Tufts, the owner of Pinehurst, the famous North Carolina resort. Mr. Tufts, when he heard of the plans of the good roads scouts, came down from his summer home in New Hampshire, hired 200 men and 100 teams and in four and one-half days constructed three miles of splendid road over which the White, with Mr. Tufts as a passenger, made an exhibition run at a rate of 50 miles an hour. Mr. Tufts is now devoting practically his entire attention, and is spending no small amount of money, in forwarding the good roads movement along the "capital-to-capital" route.

At many other points along the line special exertions were put forth to improve the roads in order that the scouts might form a favorable opinion of the "capital-to-capital" route. Bridges were built over creeks which never before could be crossed except by fording; stumps were cut out of the road; holes were filled in and, in general, people all along the route gave evidence that they had awakened from their previous attitude of letting the roads go by default.

The arrival of the scouts in their White steamer in the various towns was the "big story" of the day in the local newspapers. Between Atlanta and Washington, they did not have a single hotel bill to pay. In some cases, the local chambers of commerce looked after this item, and in others the scouts were the guests of the city. Every town, large or small, sent out a delegation to welcome the scouts, these delegations invariably including the Mayor and other prominent citizens.

A fitting climax to the series of receptions and entertainments occurred at Washington, where President Taft received the scouts and expressed his appreciation of the work which they were doing. Furthermore, the President readily consented to pose for a picture with the scouts outside of the White House.

As pointed out in a previous article, there was a latent good roads sentiment in the South before the New York *Herald* and Atlanta *Journal* embarked in their enterprise. But it needed just such a spectacular performance as the trips over the road between New York and Atlanta to quicken and crystallize the good roads sentiment. People in Southern towns have hitherto been satisfied with conditions if they had good roads extending a few miles from town in each direction. Now they are beginning to see that they cannot be satisfied with such a condition and are giving some attention to the roads from town to town. They can no longer look on a bad spot in the road with equanimity simply because it is five miles outside of town and no one ever goes out that far. They are beginning to realize the importance of having a good highway all the way to the next town. Last but not least, their local pride has been aroused and they are not going to let it be published to the world that the roads in their county are far inferior to the roads in a rival and nearby county.

One of the results of the trip of the good road scouts has been to inaugurate a strong movement to build a good highway between Richmond and Washington. The leading citizens and commercial bodies of both Washington and Richmond have entered into hearty co-operation and it is a safe prediction that before another year has elapsed the road between the two cities will no longer be the disgrace to the Commonwealth of Virginia which it is to-day. The direct road between those cities is known as the old "Telegraph road" and was described by "Pathfinder" in The Automobile of April 22. The scouts heard such discouraging reports of the condition of this road that they essayed a longer route via Gordonsville and Warrenton, but it is doubtful if the condition of this road is enough better to compensate for its forty miles of extra length. The direct road from Baltimore to Philadelphia was followed, crossing the Susquehanna river on the ferry at Havre de Grace. A vast amount of misinformation exists regarding this road. A number of years ago this road was reported to be almost impassable, and this information has been so widely disseminated that most tourists going from Philadelphia to Baltimore take a long, indirect route via York and Westminster. As the writer pointed out in the article above alluded to, no one need have any hesitation in going via the Havre de Grace route.

The good roads scouts ended their northward trip at New York on June 26 and were welcomed in behalf of the city by Acting-Mayor McGowan. Their work, however, is by no means completed, as there is still another route to be tried out, that by way of the Shenandoah Valley, Bristol and Chattanooga, Tenn., and, at this writing, the pathfinding White Steamer, with its passengers, is on its way to Atlanta by this route.

EXTENSIVE PLANS FOR LOWELL AUTO CARNIVAL

LOWELL, MASS., July 19—Plans are being drawn up on an extensive scale for the Lowell automobile carnival during Labor Day Week. There will be "something doing" every day from Monday, September 6, till Friday, September 10, and that something will include three days of automobile racing on the Merrimac Valley circuit, a day of motor boat racing on the Merrimac River, alongside the course, and a day of motorcycle events on the automobile circuit. There will be also, perhaps, a balloon ascension or other aeronautic stunt on the side.

For Monday, which is Labor Day and a holiday, the event is the automobile races for cars in classes 2, 3 and 4 under the A. A. A. piston displacement classification. The class 2 event (301 to 450 cubic inches piston displacement and 2,100 pounds minimum weight) will be over 20 laps of the course, or 212 miles; the class 3 event (231 to 300 cubic inches, 1800 pounds) will be over 15 laps, or 159 miles, while the smallest cars, class 4 (161 to 230 cubic inches, 1,500 pounds) will cover 12 laps, or 127.2 miles. The races will be started at 10 a. m. There will be trophies in each class, as well as cash prizes for the successful drivers.

A series of dash races on the straightaway, a part of the circuit in front of the grandstand, is being arranged for Tuesday. The course is one of the best that could be asked, the surface being as smooth as asphalt and the roadway straight and wide. The trials will be mostly at a mile, with flying start.

Wednesday has been set apart for the National stock chassis race, to which President Taft has been invited. This will be for class 1 cars under the A. A. A. classification, namely 451 to 600 cubic inches piston displacement and 2,400 pounds minimum weight. The race will be over 30 laps, 318 miles. Motor boat racing has been assigned for Thursday, and an excellent course is available. Friday the American Federation of Motor Cyclists will hold sway.

President John O. Heinze of the Lowell Automobile Club returned a few days ago from a tour in New York and the West in the interests of the carnival, for the double purpose of ascertaining the feeling of the makers and dealers toward the proposed races and of conferring with the A. A. A. officials concerning some of the details. In both of these he was most successful.

MAY OPEN QUAKER RACE TO FOREIGNERS

PHILADELPHIA, July 19—Although the Contest Committee of the Quaker City Motor Club has hinted at a possible opening of the entry list to foreigners for next October's 200-mile stock chassis Fairmount Park race, it seems hardly likely that there will be room for all the American makers who expect to enter cars in what will be the biggest event of the year in the East. Some of those concerns who have asked for entry blanks are talking of putting in two, and, in one case at least, three cars each. At this rate the limit of 20, beyond which the promoters cannot go by reason of the comparatively short course—a trifle under eight miles—will be reached long before the date for declaring the entry list closed.

There is quite a difference of opinion existing among the Quakers as to the effect the Contest Committee's recent letter to the American makers may have had. Some of them fear that the exclusion of foreign cars may give the public an idea of the possibility of the existence somewhere of a streak of yellow, that the opening of the list to foreign cars means a foreign victory, and that that is to be avoided above all things. The opinion is held by not a few of the committee that the admission of all the foreigners who care to enter should be welcomed on the ground that a victory will be all the more creditable to an American car under the circumstances. Those who follow the racing game closely are of the opinion that in a stock chassis event American makers have now nothing to fear from their foreign rivals, whatever may have been the situation a few short years ago.

The Quaker committee had a party of city officials out over the course last Wednesday, suggesting where improvements could be made. There are one or two short stretches where a car coming up from the rear would have to encounter some rather soft going in getting around. The officials promised that these portions would be macadamized to triple their present width long before the date of the race.

F. I. A. T. TO HAVE AMERICAN FACTORY

Many rumors have been spread that the F. I. A. T. Company was to build a factory in this country, but the first authoritative statement to that effect has just been made public. The factory is to be located at Poughkeepsie, N. Y., where the company has acquired nearly thirty acres of land. The site has the advantage of a private dock in the Hudson River and connection with the New York Central Railroad. Albert E. Schaaf will manage the new factory. Although there has been much delay, it is hoped that operations will begin by the end of the year.

NEW PROGRAM FOR ALGONQUIN CLIMB

CHICAGO, July 19—There has been a revision of the program of the Chicago Motor Club for its annual hill-climb at Algonquin, Ill., August 5, and instead of classifying by piston area as has been done for the past three years the A. A. A. classification scheme will be followed, both piston displacement and price classification being used. In addition to the usual A. A. A. events the Chicago Motor Club has been given permission to add climbs for motor buggies and electrics, which are not provided for in the A. A. A. card. The revised card is as follows:

Class A, open to any stock car fully equipped and governed by the following prices. Winner to be the car making the fastest aggregate time for both hills: Division 1, $4,000 and over; division 2, $3,001 to $4,000; division 3, $2,001 to $3,000; division 4, $1,251 to $2,000; division 5, $851 to $1,250; division 6, $850 and under. No car shall compete in any division above than that to which its price entitles it.

Class A2, same as class A except that the winner will be determined by the club formula.

Class B, open to any stock chassis (A. A. A. rules) and governed by the following table of piston displacement and minimum weights. Winner to be decided by time only.

	Piston Displacement	Weight
Division 1......	451 to 600 cubic inches........	2,400 pounds
Division 2......	301 to 450 cubic inches........	2,100 pounds
Division 3......	231 to 300 cubic inches........	1,800 pounds
Division 4......	161 to 230 cubic inches........	1,500 pounds
Division 5......	160 cubic inches and under....	1,200 pounds

No car shall compete in any division above than that to which its weight entitles it.

Class C, open to any chassis made by a factory which has produced fifty cars, not necessarily of the same model, during the twelve months prior to the event, winner to be decided by time only.

Class F, the same as class C, but having the following limitations as to size: Division 1, for cars having a total piston displacement not to exceed 390 cubic inches; division 2, for cars having a total piston displacement not to exceed 202 cubic inches. Time to decide the winner.

Class C, division 1, open to motor buggies, wheels 36 inches in diameter or over, with solid tires; division 2, open to electric. Time only to decide the two divisions.

MAXWELL TRANSCONTINENTAL IN WYOMING

Mrs. John R. Ramsey, of Hackensack, N. J., who is driving a Maxwell car on a transcontinental trip from New York to San Francisco, has reached Granger, Wyoming, breaking all women's touring records. She is accompanied by Mrs. N. R. Powell, Mrs. Atwood and Miss Jahns. The party has met with bad weather all the way from New York, and in the West the roads have been in a condition the like of which is not remembered even by the oldest inhabitant. Long detours were necessary to avoid washed-out bridges, and at some of the fords which had to be crossed the water came in over the footboards of the car. Horses were found necessary on several occasions. However, the car is still in condition, and Mrs. Ramsey expects to complete the trip.

Functions and Frailties of Motor Cylinders

BY THOS. J. FAY

IN using automobile gasoline for fuel, the thickness of cylinder walls is almost independent of bore, and the foundry possibility seems to be the ruling consideration. Measurements of a considerable number of motor cylinders of various bores, ranging between 100 and 170 millimeters, disclosed wall thicknesses of six millimeters (6 | 25.4 = 0.239").

A formula devised for the purpose of determining the required wall thickness reads as follows:

When,

P = maximum pressure in pounds per square inch.

d = diameter of bore of cylinder, in inches.

t = thickness of wall of cylinder, in inches.

k = a constant, representing an allowance for reboring, then

$$t = \frac{P \times d}{7{,}200} + k$$

The above formula is on a basis of 18,000 pounds per square inch, minimum tensile strength of gray cast iron, with a working strain of 3,600 pounds per square inch, making the factor of safety, after the cylinder has been rebored.

$$f = \frac{18{,}000}{3{,}600} = 5, \text{ after reboring.}$$

Excepting in racing car motor work, the pressure may be taken at 300 pounds per square inch, and even less in some cases involving rather low compression. Numerical examples involving extremes of cylinders, as respects bore, will afford an insight into the scope and utility of the formula, as follows:

For a cylinder with a bore of six inches, which is about as large as they are made in general practice, the formula demands, for the thickness of cylinder walls, the following:

$$t = \frac{300 \times 6}{7{,}200} + 0.0125 = 0.2625 \text{ inches.}$$

In order to be able to judge of the competence of the formula another example, using a smaller cylinder is given as follows:

For a cylinder of four-inch bore:

$$t = \frac{300 \times 4}{7{,}200} + 0.0125 = 0.1775 \text{ inches.}$$

Since the water-jacket walls do not have to sustain under a pressure of moment, it is at once a foundry problem, the question of the thickness of the walls. In continental practice, in view of the desirability of symmetry in thicknesses of walls, the jacket walls are made one millimeter thinner. The problem may be solved, affording all the protection that the occasion requires, if the jacket walls are made 0.0125 inch less in thickness than the thickness of cylinder walls as found by formula.

Effect of Sharp Corners of Cores—Fig. 25, showing vertical sections through moulds of two cylinders, one of an L, and the other of a T type of cylinder, indicates the contour of the walls of the cylinders by white, and the cores in black, with the moulding sand rammed around the exterior, as shown by cross-hatching. The parting line is indicated, and the cores are shown at their extremities tapered off to fit in bearings so as to be self-centering. Loose pieces for the bosses of the valve-stem guide are shown, and the cores, at several points, are indicated with sharp edges, thus rendering the castings defective, since strength depends upon a uniform thickness of walls, and the entire absence of abrupt turns. As a general rule it is due to defects such as these, and misplaced cores, that cylinders are found wanting in service; true, the necessity for good material must not be overlooked, but it is not, as a rule, a question of mathematical proportioning that results in inferior work; it is rather a matter that rests with the foundry, as disclosed in Fig. 25.

Pistons are made of the same material as cylinders and experience seems to indicate that the bearing surfaces afforded are better than when steel pistons are used in cast-iron cylinders, or when steel cylinders are made to serve with pistons of either steel or cast iron. Fig. 26 shows the several shapes of piston heads in vogue, and A is of a flat head, of least ability from the strength point of view; B indicates the usual elliptic formation

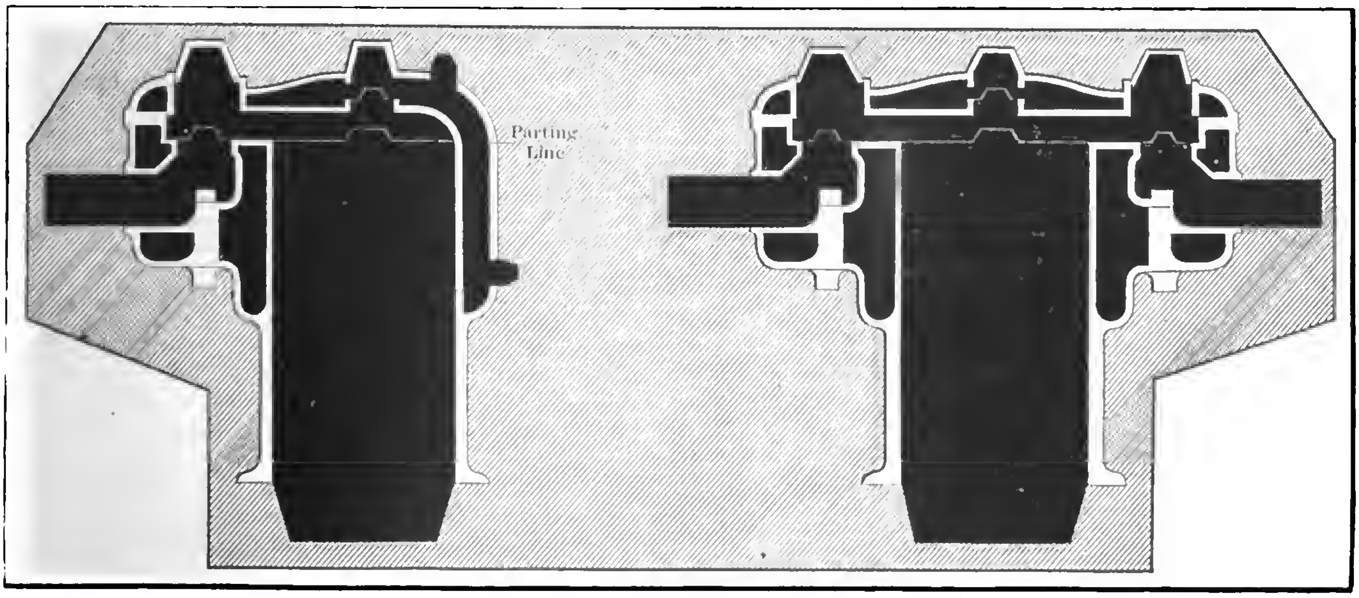

Fig. 25—Illustrating defective moulding preparation, resulting in sharp corners in the metal of the walls of the cylinders

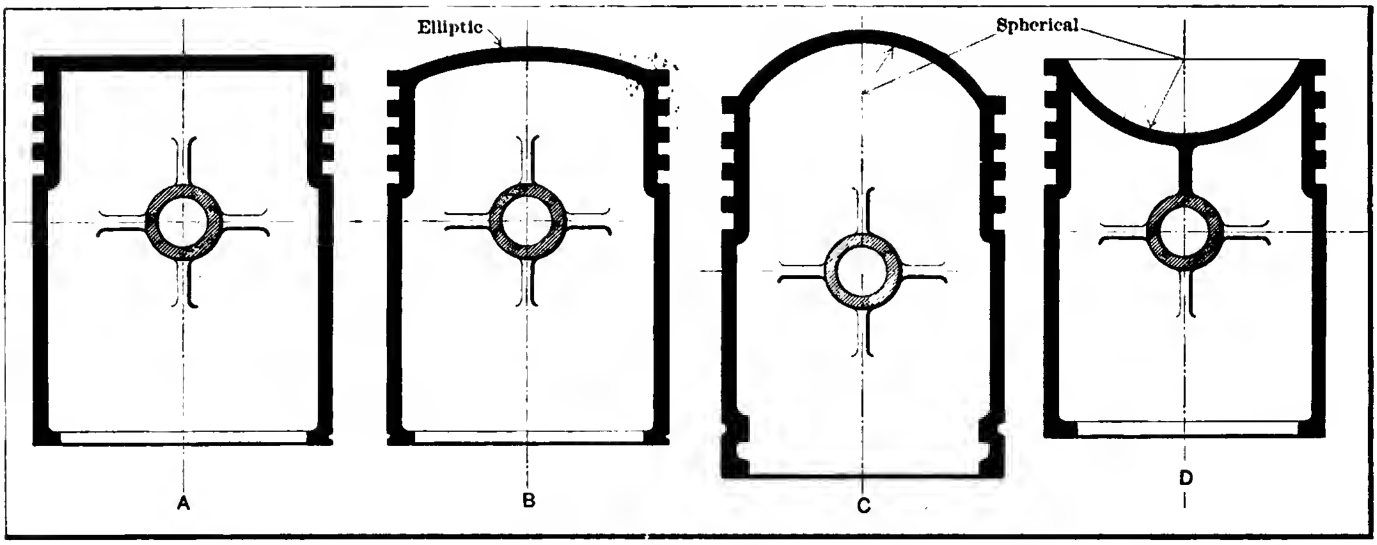

Fig. 26—Depicting the several forms of piston heads in vogue and showing the customary number of rings used

which has the merit of great strength at the junction of the head with the barrel, and lightness on the whole, so that the total weight of the reciprocating mass will be on a minimum basis if the connecting rod is suitably devised. C shows a spherical head sometimes used, and in high compression motors it has the advantage of displacing compression chamber volume and the strength of the head is maximum. D is of an inverted spherical head suitable for use on motors with a low compression, especially in the class that do not run at a very high speed, for, like C, the head is somewhat heavier than the weight attending the use of the elliptic shape as shown at B.

Influence of Ribbing on Strength and Shape—Expansion, following changes in temperature, will be uniform in a piston of symmetrical shape with uniform thickness of the walls, if the metal used is of even texture. If the ribbing is as depicted in A, Fig. 27, the expansion will not be uniform, since the ribbing is in one plane, at right angles to the axis of the piston pin; this scheme is also defective because the rib, so placed, does not lend support to the bosses in which the pin is held. B indicates ribs in two planes, so contrived that the pin supports are ribbed, and in this case the ribs are deeper in the axle plane of the pin, so placed to afford additional strength. The disadvantage of this plan lies in the difference in expansion that will follow the use of ribs of differing depth. C represents a system of ribbing that offers a more even distribution of the work, and the results in practice, from the use of this plan, are very good. When the speed of a motor is so very high that it is necessary to restrict the weight of the piston, the scheme as shown at D is substituted for that of C, and three rings are used instead of four. In all cases excepting at D the bottom of the piston is provided with an inward projection flange to add strength and rigidity to the whole; it is probably not necessary to thus add weight, and in practice it is found that pistons are satisfactory without this addition. In a few notable instances the walls of the pistons were drilled quite full of rather large holes to reduce weight, and the plan offers the desired advantage at an additional cost of construction.

Since pistons are not jacketed for water, or other cooling solutions, they are likely to prove troublesome, due to over-heating, especially in case there is any protruding part above the head in contact with the heated products of combustion, as when bolting, the heads of the bolts project into the combustion chamber. As a rule it is considered better to have the head perfectly smooth all over the exterior, which will be true when the pistons are machined all over. That the head may be very thin is true provided the walls are thickened as they approach the barrel. Oil-grooves are usually placed at advantageous points, as shown at B and C, Fig. 26, and that they aid in distributing the oil seems to be true. In some cases a ring is placed near the bottom of the piston for the same purpose, offering the further advantage of rendering the piston more tight against compression. Lubrication has a wide influence on the question of tightness, no matter how the cylinders are made, or how tight the rings may be.

(To be continued.)

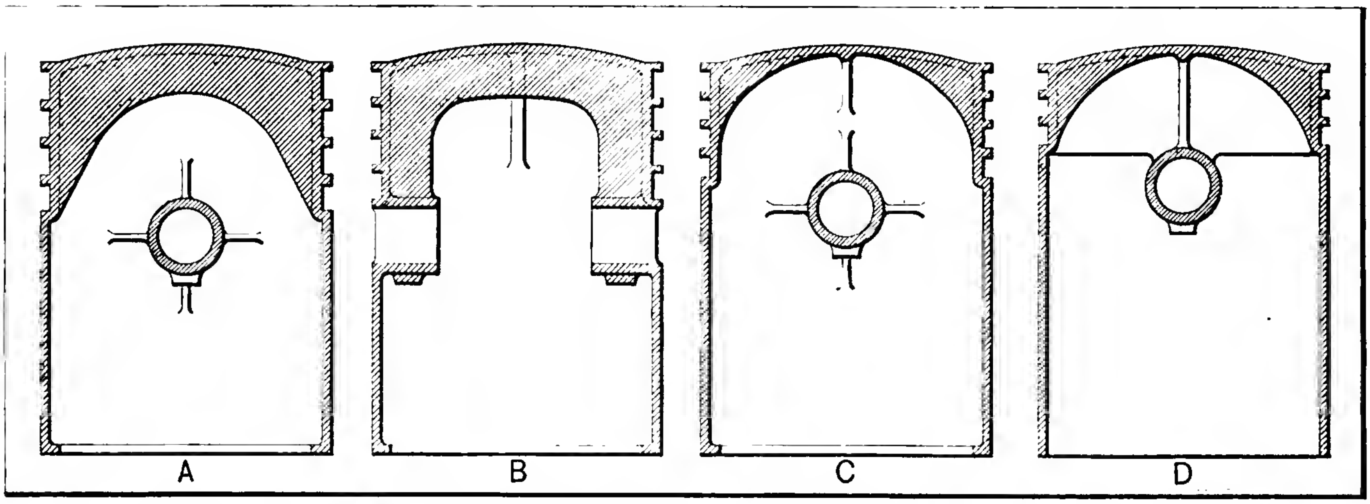

Fig. 27—Sections, showing the plans of ribbing used, and the several ways of sustaining the piston pin supports

FLEXIBILITY DESIRABLE IN AUTOMOBILE MOTORS*

By E. GIRARDAULT.

THAT quality of the internal combustion motor usually referred to as "flexibility" conveys to the mind of the average autoist but a vague idea of what is really meant. Study of a number of tests has led us to attempt to formulate a number of the more important factors bearing upon this quality in a manner that should be of interest to the automobilist. This has been carried out with the aid of M. J. Bethenot, a well-known electrical engineer. We will make the results of this investigation plain here, accompanying it with elementary demonstrations, from which there have been eliminated as far as possible mathematical formulæ and the jargon of the mechanic. It will also be possible to realize from this the influence that the matter of flexibility in the motor should have on the design of the car, and particularly on the change speed gear.

It is a matter of common knowledge that the power of the explosion motor varies according to the speed at which it runs. The same motor will give a maximum of 10 horsepower at 600 revolutions, for example, and 16 horsepower at 1,200 r.p.m. If there are marked off on a straight horizontal line *om*, points denoting the number of turns of the motor per minute, and each point thus obtained, a vertical line is raised, across which at proportional heights lines representing the increasing horsepower are drawn (measured experimentally with the brake), points such as T, A, M, etc., which indicate the horsepower of the motor, are obtained. Joining these points with a line, a curve is obtained representing the variation in the power with differences of speed.

At the same time as the power curve is traced—that is, the work done by the motor per second—we may also outline the curve of the couple; in other words, the energy delivered by the motor at each turn. The second curve may be traced point by point, from the first, the energy per turn being deduced from that per second by means of the rule of three, since the number of turns per minute is known. Experience has demonstrated that the two curves in question take the form shown in the accompanying diagram of flexibility.

There may also be deduced from the power curve the curve of the couples without the necessity of calculating the couple for each point by proportion. Let us join the point M by a line with any one of the power indications having their origin at O. The triangle O*Mm* will give us the formula:

$$tg\,\alpha = \frac{Mm}{Oo} \;\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

Mm represents the power of the motor at the speed of rotation measured by O*m*. Now the quotient of the power by the number of turns per second is exactly equal to the couple; that is, $tg\,\alpha$ represents the motor couple. The couples may then be measured on the diagram by the segment *uv*.

By dropping a perpendicular from M until it meets a line extended horizontally from *v*, the point *n* is obtained, indicative of the couple represented by the conditions O*m*.

It may be remarked that the maximum couple is obtained when α is highest; that is, when the straight line joining O and M is elevated as much as possible, since then it is tangent to the power curve, and by this means it will be easy to recognize conditions under which the motor will be in danger of stalling. It will be apparent that this is knowledge which should be interesting to the purchaser.

The curve of the couples indicates that the maximum is at C, the point where the tangent is horizontal, while the power curve has its maximum at A. In the case of the motor from which the curves here illustrated were taken the maximum couple was registered at 400 r.p.m., while the maximum power was delivered at close to 1,000 r.p.m. To generalize, we will designate by *n* the conditions corresponding to the maximum couple, and by *N* normal conditions, under which the maximum power is developed.

Inasmuch as the resistance offered the motor is constant and the conditions of running are equally so, the motor continues to operate practically the same. This is the case of an automobile motor with a steady, harmonious exhaust. As soon as the car begins to mount a hill the motor cannot continue to advance the vehicle at the same speed, and it slows down; as its r.p.m. rate falls off, the power decreases correspondingly. Let us consider the curve of the couples. Since the motor is at a point superior to *n* turns (on the diagram 400 r.p.m.), there is no fear of stalling, because the effort produced by each turn becomes greater as the motor slows down. We have already said that between *n* and N the motor is in its zone of stability; that is, the zone in which the motor will not stall. But it may be that its speed will be retarded to a point below that of *n* turns. Then it will not be capable of producing sufficient power at each revolution to carry the load imposed by the grade. The motor will be stopped unless

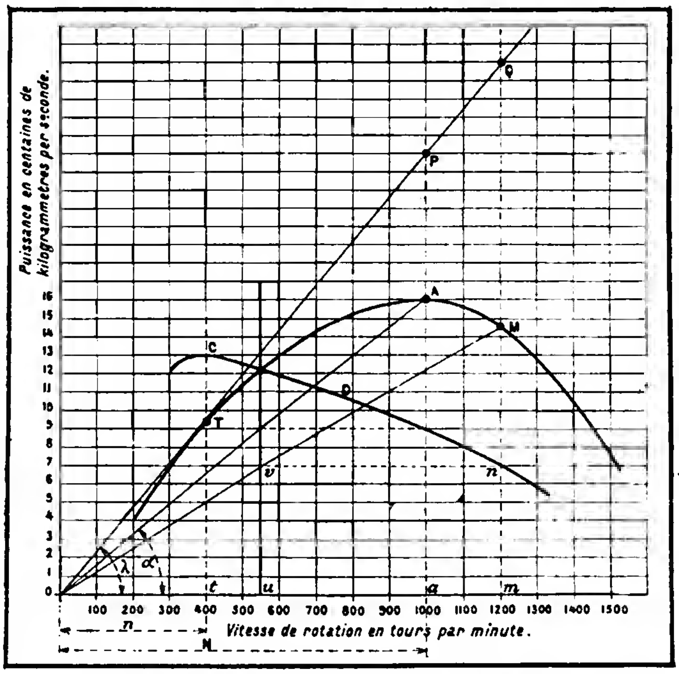

Diagram Representing the Flexibility of a Motor

Vitesse de rotation en tours par minute = speed in revolutions per minute. Puissance en centaines de kilogrammetres par seconde = force in hundreds of kilogrammeters per second = force in units of 13.83 foot-pounds per second.

recourse is had to a change in the gear ratio between it and the driving wheels. This elementary reasoning is evidently applicable to the condition attendant upon the change of gear. The lack of flexibility of the automobile motor makes it imperative to be able to vary the gear ratio of the transmission is the way this is commonly stated.

We have observed that the change of speed should be made at the point where the speed threatens to fall below that of *n* of the maximum couple. Once the lower gear ratio is in action, the motor will resume its normal speed. From the point of view of efficiency it will evidently be advantageous to have the motor run continuously under conditions which permit it to develop its maximum power. But we will see further on that it is not always possible to design a change of speed gear-set so that the different steps may be effected at the normal speed of the motor. But for the moment we will assume that this is the case, subsequently modifying the simple conclusions which this hypothesis furnishes.

Briefly, the motor oscillates between the two extreme condi-

* Translation from the French of "Omnia," by Charles B. Hayward.

tions, n and N. Being at the point n, which gives the couple C, we pass with the aid of the change speed lever to the point N, which gives the couple c. The relations between the corresponding steps in the gear-set are evidently equal to the relations between the couples $\frac{C}{c}$, since this is also the ratio between the effort required per turn of the wheels at the different speeds.

If we substitute for the couples their values in functions of the power and the speed we obtain for the constant ratio s of the steps (also termed the speed ratios):

$$S = \frac{N}{n} \frac{w}{W} \quad \ldots\ldots (2)$$

in which N is the number of turns at normal speed, giving the maximum power.

W is the maximum power.

n, speed at which maximum couple is produced.

w, power corresponding to the speed at which the maximum couple is produced.

The constant ratio, which theoretically is that of the two successive speeds, measures the flexibility of the motor.

The speeds provided by the gear-set are, assuming v_1 to be the first: v_1 $v_1 \times s$ $v_1 \times s \times s$ $v_1 \times s \times$.

In other words, s, the flexibility of the motor, is the reason for the geometric progression of the speeds.

However, the speeds will no longer be in geometric progression when the resistance of the air is taken into account. The higher speeds must be lower than those indicated by the progression.

We will also show that the flexibility as thus defined is susceptible of a very simple geometric calculation, and that s may be obtained graphically by tracing the power curve of the motor. Taking the power curve and the point of origin, O, produce the tangent shown. The right angled triangles OPa and OTt give:

$$Pa = Oa\,tg\,\lambda$$
$$Aa = Oa\,tg\,\alpha \quad \ldots\ldots (3)$$

From which:

$$\frac{Pa}{Aa} = \frac{tg\,\lambda}{tg\,\alpha} \quad \ldots\ldots (4)$$

It is already known that the tangents measure the couples, and that the ratio of the couples measures the flexibility of the motor.

The equation $\frac{Pa}{Aa}$ accordingly measures the flexibility.

It will be seen that this relation is always greater than unity, but in automobile motors it exceeds that figure very slightly, i. e., 1.2 to 1.5. With the first figure, 1.2, for instance, it will be evident that a great many steps would be required in the change speed gear if the conditions we have outlined are to be met. But in practice, recourse is had to an artifice for taking care of the lack of flexibility in the explosion motor; at the moment that the speed of the car is to be changed the motor is speeded up.

The following shows how this well-known custom of the chauffeur may be rationally justified. Our figures give the explanation sought. It is, in fact, that the condition Om, superior to N, is attained by the motor when it is speeded. If the gears then be shifted the relation s of the two consecutive speeds is represented on the diagram by $\frac{Qm}{Mm}$. It will be seen that this ratio increases very rapidly as the motor drops from normal. It may be said that this ratio represents the flexibility of the condition Om, and defines the flexibility at any given speed.

But in running the motor above its normal speed at the moment of gear shifting, the flexibility is increased at the sacrifice of efficiency and the life of the mechanism, this being necessary to avoid having to employ too many gears in the transmission. But, naturally, those motors which require the minimum of speeding will be preferred; that is, those possessed of the greatest factor of flexibility at normal speed. The ideal would be to obtain a motor having a coefficient of flexibility of at least 1.6 at its normal speed, which would eliminate the necessity of racing.

From this it may be appreciated that the coefficient of flexibility, of which the expression and geometric demonstration are so simple, is a very important characteristic of a motor, and that builders should give it quite as much as they do the consumption per horsepower hour of their motors, since it is intimately related with the necessity for using the gears—an enormous source of expense in cabs and autobuses.

Another result of the foregoing investigations is to bring forward very prominently the advantages of a four-speed gear over one having but three steps, from the point of view of fuel consumption and life of the motor, for the more speeds there are and the less the speed of the motor has to be varied the less necessity will there be for handling the change speed lever. This advantage disappears, however, with a motor sufficiently flexible to make gear changing possible at the normal speed of the motor.

To increase the flexibility, devices designed to regulate the carburetion in proportion to the speed are commonly employed. These may be classed in two groups, those producing throttling at the higher speeds and those which impoverish the mixture as the speed increases. The first class is inferior in principle, because throttling lowers the degree of compression and in consequence the efficiency, while the employment of a poorer mixture tends to maintain this at the maximum. This expedient is not without its disadvantages, however, the first of which is the necessity for avoiding auto-ignition, since the compression employed at high speeds with a poor mixture must not be the same as that at low speed, when a rich mixture is necessary. Otherwise, auto-ignition is inevitable with the latter, from which there arises the necessity of throttling at the lower speeds.

To sum up, it always ends by arriving at a point where the efficiency of any given motor must be sacrificed, but it will evidently be better to do this at speeds rarely employed than at the normal r.p.m. rate of the motor. This is because we are able to employ a system of carburetion which will reduce to a minimum the expense for fuel and gears—both items of considerable importance. One objection that may be urged against the use of poor mixtures at higher speeds is the low factor of power per weight thus obtained *(puissance massique)*. We are, in fact, compelled to employ motors which produce all the power of which they are capable under normal conditions; that, is with normal mixtures, bore, volume and weight being considered. Is that a great drawback? We hardly think so, especially for industrial vehicles. It is interesting to note how little power per unit of weight may be employed, and how great the total weight may be raised, but within certain limits there should be no fear of employing somewhat heavy and relatively slow motors of great capacity, with the compression as high as possible and employing fuel mixtures which become poorer as the speed increases. This, of course, for the autobus and the truck.

To make a résumé, it will be seen that studying the question of flexibility has led us to considerations of other parts of the vehicle, and particularly the choice of the motor, construction of the change-speed gear and the regulation of the carburetion. Advantage has been taken of the foregoing in the touring car, and builders have been asked to reduce the horsepower to one-fourth of what it is. It may not be beside the point to remark that foreign engineers head the commercial vehicle industry, because they do not build their cars on sentiment, but according to the needs of economic exploitation, which involves mechanical problems that must be solved.

Removing Foreign Substances from Cylinder—Sometimes a foreign substance, such as a piece of porcelain from the spark plug, the key of an automatic inlet valve, or a small washer, falls into the cylinder. Such substances can be easily expelled by removing the exhaust-valve cap and turning the motor over by means of a starting crank, when the fragment will be shot out into the air, very quickly.

LETTERS INTERESTING AND INSTRUCTIVE

USE OF CASTOR OIL

Editor THE AUTOMOBILE:

[1,948]—To settle an argument, will you kindly answer the following question: Is it not only possible, but also good practice, to use the best grade of castor oil for lubricating a high-speed engine, at, say, 1,000 r.p.m.? By this is meant a gasoline engine such as is used in automobiles.

Lebanon, Pa. C. L. WEIMER.

Yes, it is not only possible to use castor oil as a lubricant for automobile engines, but is also representative of the best practice. In fact, it is more than that—it represents the very highest practice, being used upon racing machines, where ordinary lubricants would not answer. Particularly is this true of very high compression motors in which the pistons and piston rings must be an unusually tight fit in the cylinders. For these, castor oil is the only thing that will serve the purpose. Its universal use is very limited because of the price, which is far beyond that which ordinary motorists are able to pay. There are several cars built in this country the makers of which advocate the use of nothing but castor oil for the cylinders, although other oil may be used elsewhere on the machine.

OFFSET CRANKSHAFT

Editor THE AUTOMOBILE:

[1,949]—Please set forth in "Letters Interesting and Instructive" the advantages of an offset crankshaft; also, of a long stroke motor; that is, small bore and comparatively long stroke. R. N. HICKMAN.

Cleveland, Ohio.

The principal advantage claimed for the offset crankshaft construction is the elimination of the side thrust of the piston on the cylinder walls, during the power stroke. By eliminating this, it is possible to increase the power from the same sized cylinders and at the same speed. The disadvantage to which the most weight is attached is just the reverse of this; the side thrust on the return or compression stroke is increased over what it would be on an engine with shaft set central. The amount of the off-set differs with different cars. The usual range is from one-quarter inch to an inch and a quarter, but a formula for it has been advanced. This, which was given much discussion about a year ago, was one-fifth of the stroke for the amount of the off-set. So, with a 5-inch stroke, the off-set would be one inch.

This formula does not hold, however, to any extent, as the few users of off-set shafts do not agree on the subject, some advocating more off-set up to one-quarter of the stroke, and others advising the use of less, even down to one-eighth of the stroke. The fact remains that it is not or should not be an arbitrary constant quantity like that, but should be proportioned to the other parts of the engine. Thus, with a very short stroke motor, in which short connecting rods are used, a large offset would be more desirable than in the case of a long stroke motor with long connecting rods.

Much discussion has attended the attempt to determine the superior length of stroke. Prominent French makers not only advocated but adopted the longer stroke. English makers, on the other hand, were more given to short strokes, and still stick to them. It remained for the races in which an unlimited length of stroke was allowed to prove the point to the satisfaction of all—French, German, English and American. Thus, in the English Four-Inch race the bore was limited to four inches, but the stroke was unlimited. The result was that several machines were constructed with abnormal strokes which were able to deliver on the testing block as high as 71 horsepower. So, too, in the more important Continental contests the stroke has been unlimited, with the result that a series of abnormal racing motors has been developed, many of them having a stroke twice the bore.

At any rate, it has been proven that both more power and greater speed may be obtained with very long strokes—this, too, on racing motors, which are nothing if not light in weight. So, one of the most weighty arguments against the long stroke was laid to rest by this experience. It is argued in its favor that by allowing more time for each of the cycles they are more complete, and consequently more perfect. Take the exhaust stroke, for instance: this has a much greater length of time in which to take place, and is more effectually carried out. Similarly with other functions.

It is argued also that with slower engine speed less reduction is necessary between the motor and the road wheels, resulting in a less amount of gearing, and consequently a lessened number of control rods and levers, all of which adds to the so-desirable simplification of the automobile.

Without desiring to go into this matter to any greater extent here, the reader should know that this does not by any means cover the subject. Those interested in pursuing the matter further are referred to the following articles which have appeared in the columns of THE AUTOMOBILE recently:

August 27 issue, 1908, pages 293 to 295.

September 17, 1908, pages 397 to 398.

September 17, 1908, issue, an additional article on page 398.

December 24, 1908, issue, page 897.

The matter of offset crankshafts was gone into very thoroughly under "Letters" in the May 20 issue, THE AUTOMOBILE.

ABOUT HIGH ALTITUDES

Editor THE AUTOMOBILE:

[1,950]—My attention has been called to several unusual problems in automobile work and I take the liberty of asking you to give me your opinion on same. Also, please inform me if you have ever published any answers to the following questions, and when:

Question A—Suppose I toured through the West in my car, built by an Eastern builder, and during my trip I arrived at the city of Denver. The altitude of Denver is, I believe, about 5,000 feet above the sea level.

First—What effect would the lessened atmospheric pressure have on the carbureter's action? Could I remedy same, and how?

Second—Would the lessened pressure effect to any noticeable extent the work of the gas mixture in the cylinders?

Third—Would the explosive pressure be less by reason of the air being lighter and having a correspondingly smaller amount of oxygen per cubic foot?

Fourth—Would not the water, by reason of its lower boiling point at this altitude, permit the cylinders to become dangerously warm?

Question B—What arguments are advanced for or against the use of sub-frames upon which to place or suspend the power plant—that is, the motor and transmission gear? E. B. G.

Elyria, O.

In reply to the first paragraph of question A, the lessened atmospheric pressure would lower the gasoline level in the float chamber relative to what it is at present in a lower place. To remedy this, lower the nozzle, which will raise the level of the liquid, lowering it enough to compensate for the difference in pressure of the present place and Denver, one mile up. Similarly, the air there is thinner and more rarefied, so a greater amount of it will be needed to vaporize the same amount of fuel. To remedy this it will be necessary to open up the auxiliary air inlet, so that more air may enter, accomplishing this according to the construction of your carbureter. It might seem like needless work to make the two alterations to the carbureter—raising the spray level and allowing more air to enter, when a person might think that the lower level would require less air—so the same result would be accomplished by leaving both as they are at present. However, this supposition is contrary to fact, for the engine needs just as much fuel, which can not flow if the level in the float chamber is reduced. Therefore, you must alter the position of the spray nozzle. If this is done, it will also be necessary to alter the air supply.

Second paragraph: No.

Third paragraph: Yes; if no changes are made in the carbureter adjustments. No; if the changes are made as indicated above.

Fourth paragraph: Yes; this will have a marked influence, and more care will have to be used in running the engine so as to heat the water as little as possible. Similarly, more care will have to be exercised in filling the radiator, which should be filled oftener—that is, kept filled more carefully than is the usual case.

Question B—There are two reasons which are ordinarily advanced against the use of sub-frames, differing widely. One is a constructive reason, cross members and sub-frames cost more than extended arms on crankcase and gearcase and also cost more to put into place. By increasing the number of joints in the suspension, the number of sources of trouble is also increased. The other reason is one of principle, the opponents of the use of sub-frames saying that it makes too rigid a frame construction, so that the inequalities of the road are transmitted to the crankcase and gearcase; thus rough roads are very liable to cause a fracture of the arms of one or both, through no fault of their own, but simply from the fact of its being rigidly tied to the sub-frame. In three-point suspension, which has many adherents, the elimination of the sub-frame is practically necessary to the completion of the three-point construction—that is, the idea could not be carried out with a sub-frame.

In favor of the use of sub-frames, it is argued that it allows of the segregation of the power parts, as engine, transmission, clutch, etc., into a number of separate and distinct units, each complete in itself, machined, assembled, and repaired separately. With long arms on the crank and gearcase attaching them to the main frame, the important parts of the car's mechanism are supported on castings which are unreliable, whereas in the use of a sub-frame the very short, stiff, and strong arms are supported from a sub-frame of steel, so that the whole is more reliable.

TO STOP THAT NOISE

Editor THE AUTOMOBILE:

[1,951]—Relative to the letter (1,926) of Don S. Numbers in the July 1 issue of "The Automobile," there are six blots that hold the brake drum to the rear wheels. By taking off the wheels it will be found that these strike the mechanism of the brake. Clipping off the ends with a chisel will cause the noise to disappear. I had the same trouble with my model 10 Buick and cured it in this way. N. S. HEGNES.
Argyle, Minn.

By blots the writer of the above evidently meant bolts, the two letters having been transposed by accident. This remedy might be tried by Mr. Numbers, and if not successful doubtless other similar sources of trouble will present themselves later.

ANOTHER VIEW OF IT

Editor THE AUTOMOBILE:

[1,952]—Inquirer 1,926 will undoubtedly find upon close examination that the light clanking noise in his Buick Model 10 comes from looseness of the emergency brake bands. These bands should have very little side play, else vibration will cause them to continuously tap the brake drum and thereby produce the light clanking noise spoken of. Upon removal of the wheel from the axle the proper remedy will be apparent.
Park River, N. D. F. J. PROCHASKA.

Since the above letter presents another view of the light, clanking noise trouble and a remedy for the same, it is given in full. Several other letters treating of this same trouble have been received and will be published in later issues.

CARBURETER TROUBLE

Editor THE AUTOMOBILE.

[1,953]—Will you explain in "Letters Interesting and Instructive" what is wrong with a 1906 model Indian motorcycle? It starts hard and the primer has to be held down. Then it will run about 200 yards, when the primer has to be held down again. Sometimes even this remedy will fail. I have had the carbureter apart and it is in good shape and clean. The spark seems to be very good at all times.
Hazleton, Pa. SCHUYLER PARDEE.

Since your spark is good, the trouble must be in the fuel system. It appears from your description as if you were starving the engine, although doing so unconsciously. This starving action is due to the fact that the gasoline level has been lowered so far that the suction of the engine does not draw up sufficient fuel for running. The fact that you have to prime to start and then, prime to keep a going, even this priming failing to work sometimes, would seem to prove that the engine is not getting enough fuel. The trouble is that the spray nozzle has been raised too high, so that the gasoline level is four or five times as far below the nozzle as it should be.

The engine suction must raise the gasoline this distance before any of the fuel will get into the cylinder, and if the distance exceeds the height which the suction has ability to raise the fuel, none will pass over. In a case of this sort, priming only helps temporarily.

It might be of interest to you to refer to the answers to others who have had the same trouble, and particularly the ones which were illustrated, as the figures may help you out in your present dilemma and aid you in understanding our explanation. Letter 1876 in the May 13 issue of The Automobile discussed the effect of change of jet elevation. Then, in the June 17 issue under the heading of "Cause of a Bad Knock," this was enlarged upon and a figure shown, which illustrated the effect of a variation in the nozzle level. The latest "letter" on this subject is 1940, in the July 15 issue, just off the press, in which this subject is spoken of incidental to a number of other troubles.

WHERE FORT ANCIENT IS

Editor THE AUTOMOBILE:

[1,954]—In your issue of July 1 appears an article, "Climbing Fort Ancient Hill—41 Miles from Cincinnati." I take exception to the statement that it is directly east of Cincinnati on the C. H. & D. R. R. The fact is that it is located five miles east of Lebanon, O., the county seat of Warren county, on the Little Miami Railroad and the Little Miami River. Again, the writer of the article says that Fort Ancient will become "historical." The fact remains that it is historical since it is the fort built by the mound builders and is now owned by the State of Ohio and is being laid out as a State park to perpetuate as far as possible this natural fortress and the remaining earthworks built by this unknown people.

The nearest the C. H. & D. approaches Fort Ancient is 20 miles west. I made the climb a year ago and until recently resided in an adjoining county. My object in writing is that such a point as Fort Ancient should be properly located geographically.
Los Angeles, Cal. C. O. RICHTER.

Mr. Richter misunderstood the use of the future tense in connection with the statement, "Fort Ancient *will* become historical." The idea to be conveyed by this remark was that the hill will become famous in connection with hill-climbing contests, just as Dead Horse, Giant's Despair, Fort George, and many other hills which doubtless were historical in so far as they were connected with incidents of American history years and years before the automobile was ever dreamed of.

WHAT TO DO ON WET PAVEMENT

Editor THE AUTOMOBILE:

[1,955]—Kindly advise me what to do when in driving an automobile on wet, slippery asphalt or wood pavement, the car skids and starts to whirl around. This is particularly liable to happen when an attempt is made to slow down or stop the car.
Westfield, Mass. H. P. MOSELEY.

There are two methods, both on the order of preventatives: equip your car with tires having a non-skid tread or use chains. If you do not care to do this, avoid wet or slippery pavement, just as you would mountains, rocky roads, or anything else dangerous. If it is absolutely necessary to drive over a slippery piece of pavement, start onto it and proceed across it, with a speed reduced as low as possible. When approaching such a piece of road retard spark, reduce throttle, and change down into a lower speed. The very erratic movement of a fast-moving car upon a slippery pavement, particularly, as you have remarked, when slowing down, has never been satisfactorily explained. At best, it represents a source of imminent danger and should be approached with much care and treated as such.

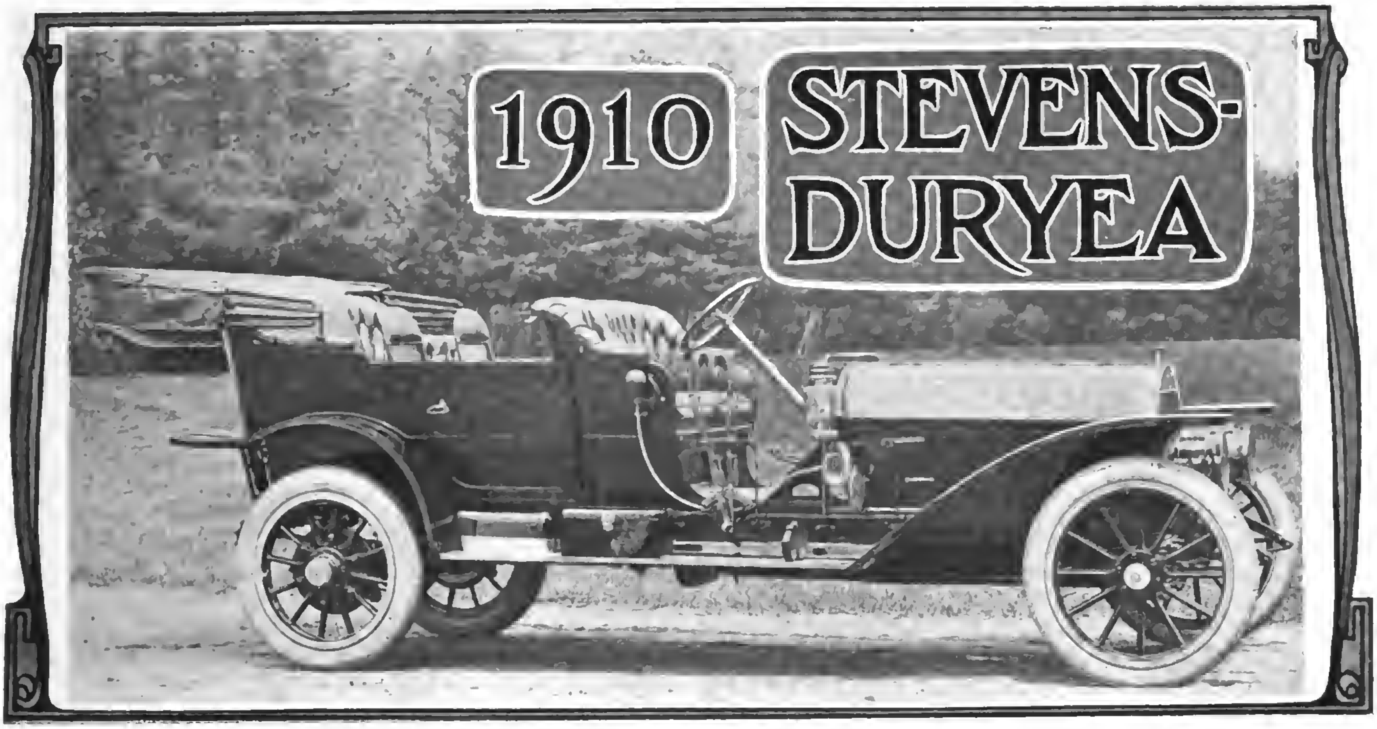
CONTEST RULES UNJUST?

Editor THE AUTOMOBILE:

[1,956]—As manufacturers of light-weight cars we would like to make public protest in your reading columns against the rules laid down to govern the so-called "light car contests." At the present time in all the light car events for the next two or three months, where piston displacement is the basis of qualification, a minimum weight of chassis of 1,800 pounds is called for. What chance has a manufacturer, like ourselves, who does not build a car that weighs to exceed 1,700 pounds, to show his cars in competition? The ruling gives an unfair advantage to the builders of heavy cars with small motors, and leaves the light car manufacturer completely out in the cold.

Automobile racing is supposed to have its greatest value in assisting to determine the most defective and least practical design. If a manufacturer is able, as we claim we are, to build a 36-horsepower engine, place it in a car with a carrying capacity of five persons and show a total weight for car and equipment of less than 1,700 pounds, why should he not be permitted to demonstrate in important contests in competition with other manufacturers that his idea of construction and proportion of power to weight is superior? In other words, why should we not be allowed to take the chassis of our 1,675-pound five-passenger car and place it in competition with other cars of our same rated horsepower? In a race of 250 miles if light cars can stand the racket better than heavy ones, why should not the light ones get the credit, and vice versa?

We claim an advantage over the heavy car, and the heavy car manufacturers claim an advantage over the light. Why should we not be allowed to get together on the same footing and fight it out? All we want is a chance with cars of our same power, but at the present time the best we get is a chance to compete in free-for-all events with no limitations of any kind, which proves nothing of value to the builder and merely furnishes good sport for the spectators.
CAMERON CAR COMPANY,
Beverly, Mass. H. W. DOHERTY.

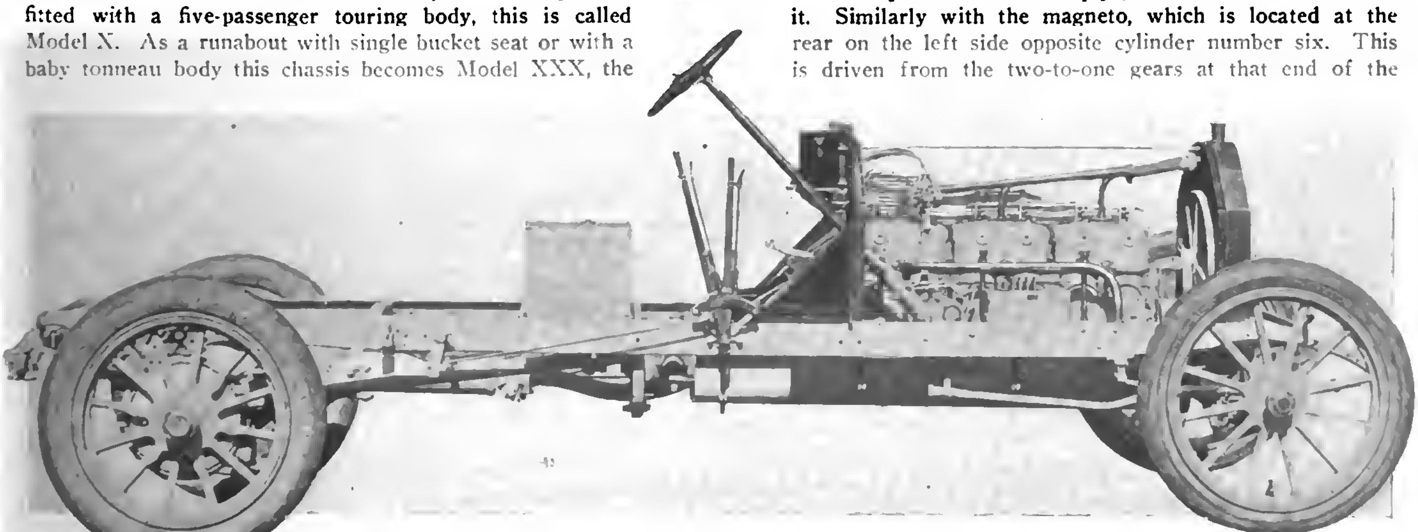


Big Six, the Stevens-Duryea Leader for 1910, a Forty-Horsepower Seven-Passenger Touring Car

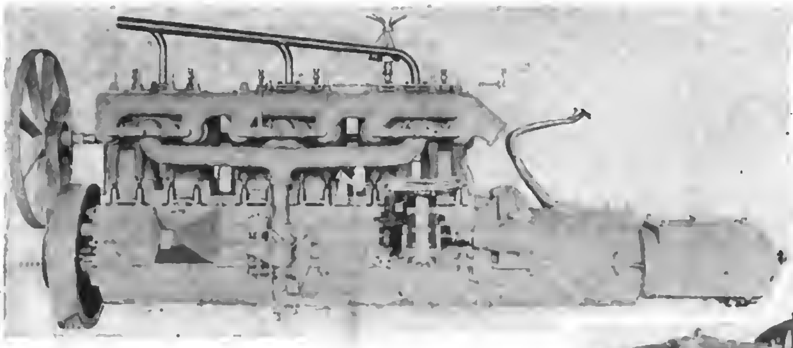
OF long standing, but up to date, is the complicated and somewhat paradoxical phrase which describes the cars of the Stevens-Duryea Company, Chicopee Falls, Mass. Since 1905 this concern has been the steady and aggressive exponent of the six-cylinder engine for large powers, and the output for the coming year will contain an excellent example of this form of construction. In addition to this, the New England concern has advocated the unit power plant with three-point suspension ever since 1904, and the cars for the season of 1910 will all contain a power plant constructed along these lines. Such was the clarity of the original ideas in both that no changes have been made from that time to this, and as the present product shows, the construction has not been altered from the first car built.

Next season's leader will be the old standby, Big Six, a six-cylinder forty-horsepower car called Model Y, with cylinders of 4¾-inch bore and 4½-inch stroke. As a standard equipment this will have a roomy seven-passenger touring body. Then there will be two "fours," differing mainly in the bodies and the little changes that go with the different bodies. The motor is 4¾-inch bore and 4½-inch stroke, rated at twenty-four horsepower. When fitted with a five-passenger touring body, this is called Model X. As a runabout with single bucket seat or with a baby tonneau body this chassis becomes Model XXX, the power unit of Models X and XXX being identical. The former, however, has a 124-inch wheelbase and will take limousine or landaulet body interchangeably with the touring body. Model XXX, on the other hand, has a shorter wheelbase, 109 inches, and so will not take the enclosed type of body. Moreover, in keeping with the idea of a light, fast car, the springing has been altered, the rear springs on the X being platform, with 48-inch side members and 35-inch cross spring. On the XXX model this is changed to semi-elliptic, 56 inches long.

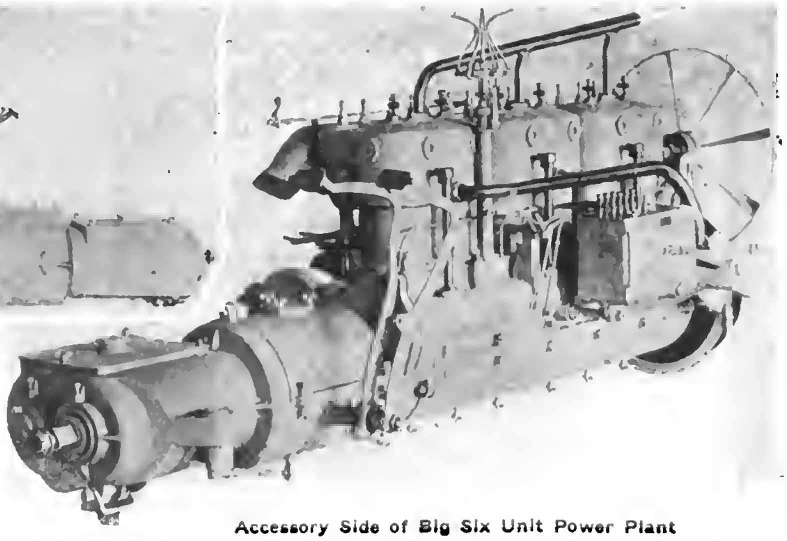
Big Six Power Unit—Model Y is powered with a six-cylinder engine of 4¾-inch bore by 4½-inch stroke, rated at forty horsepower. The cylinders are cast in pairs, with integral water jackets and valves located all on the left side. The construction is so planned that nearly every part ordinarily removed may be taken off without disturbing the others. Thus, the exhaust pipe rises above the exhaust ports and passes across the upper part of the cylinder, while the inlet pipe drops down below the line of the openings, in this way making each pipe removable without disturbing the other. The carbureter is made integral with the lower part of the intake pipe, and can be removed with it. Similarly with the magneto, which is located at the rear on the left side opposite cylinder number six. This is driven from the two-to-one gears at that end of the



Appearance of Model Y, Six-Cylinder Chassis, when the Body Is Removed



Inlet and Ignition Side of Six-Cylinder Engine



Accessory Side of Big Six Unit Power Plant

engine through the medium of a small universal joint, which relieves all strain upon the armature shaft, while at the same time allowing the removal of the magneto complete without disturbing anything else. To take off this important accessory it is necessary to loosen but one bolt, the one holding the flexible strap, when the magneto may be pulled forward and up. This rear position of the magneto is claimed to be of special merit, for it is removed from all mud, dirt and water so prevalent at the front end of the chassis.

In the driving gears just spoken of, silence is obtained by the use of fiber for the gear faces, this also doing away with the necessity for lubricating the gears. Camshaft bearings are held in place and adjusted by means of a series of set screws projecting above the surface of the crankcase. These allow of adjusting the bearings or changing the position of the shaft without taking it out. The latter operation is also facilitated by this means, since to take the camshaft out it is only necessary to loosen these screws, two in number, and draw the shaft out.

Cylinders are of special gray iron, ground to size, after a preliminary machining operation. In grinding, water is circulated through the cylinder, wiping out the heat of the grinding wheel and in this way permitting the highest possible rotative speed, which is attended with the best results.

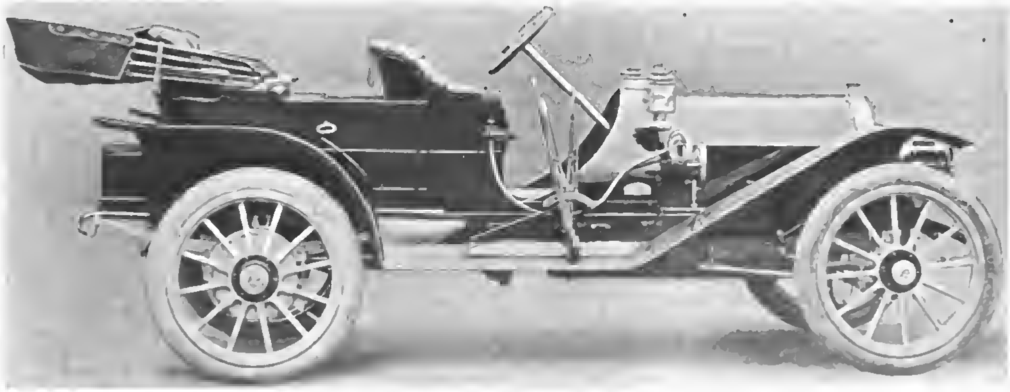
Accessories Located on the Right Side—Opposite to the camshaft side, with the carbureter, is the rest of the accessories, located together on the right side of the motor. These include the oiler, pump, timer and the fan drive, which is, however, located at the front. The oiler is carried from the side of the crankcase by a pair of bolts which pass through the base of the oiler. At the front end a cross-shaft drives the pump and oiler. The pump is of the centrifugal type, and the forward position is a change from the old location, which was in a vertical plane alongside the crankcase. Now it is in a vertical plane, but forward, opposite cylinder number one. The pipe is graduated in size from the pump back to the rear cylinder-block, changing diameter at every point. So, too, with the outlet pipe on top of the cylinders; this is of a gradually increasing section, while at the same time it gradually rises to the radiator inlet, so that there are no sharp bends, usually so disastrous, in the water circulating system.

A timer with six contacts is located between the second cylinder casting and the third. This is placed on top of a vertical shaft which is driven from the camshaft on the opposite side of the engine by means of bevel gears. The forwardly located fan is mounted upon a forged arm attached to the motor base, and rotates on ball bearings. It is driven from the crankshaft extension by means of a flat belt.

From the oiler, just described, the oil is forced to the main bearings, where, after lubricating, it flows to the lower part of the case. There it forms the source of supply of a splash lubricating system, which caters to the piston, connecting rod and cylinder walls. To drain the oil, pet cocks are provided, and to fill the case when emptied the breather pipes—three in number, seen in the view of this side of the engine—are used.

An important feature of the engine, not apparent from any of the views, is that of accessibility of the pistons, which may be removed from the cylinders bodily by removing the lower half of the crankcase, the bearings being attached to the upper half. These bearings are four in number, of babbitt.

Chrome Nickel Steel the Transmission Material—The transmission affords three speeds and a reverse, sliding gears being the medium. These are operated on a quadrant, which shows the Stevens-Duryea individuality. The shifting lever carries a pin which projects through one of the side bars of the quadrant. The slot in the bar is cut with two levels, a low and a high, the lower notch being in two parts, the forward and the rear part. The higher slot unites the other two. At the ends of the notches there are enlargements into which the pin drops so as to preserve the position. In the middle of the upper part, which provides for the low and second speeds, is placed the notch for neutral. This makes the shifting progressive from the low to second to high, and from neutral to low to reverse.



Model XXX, Four-Cylinder, Looks Right with Baby Tonneau Body

Chrome nickel steel is the material of the gears and the shafts also, both being cut from the solid. Aluminum is the crankcase material, the barrel shape being adhered to for strength. The top of the case is closed by means of a flat cover, in the center of which is a filling cap. This serves to fill the case with lubricant, without the bother of taking off the cover.

Between the transmission and the engine is placed the clutch, which is of the multiple disc variety. This is the same clutch as was developed by this company in 1904, consisting of a number of steel discs, half of them being faced with an almost indestructible lining. This is an asbestos material, composed of woven wire and asbestos fiber, the idea of its use being the increase in the coefficient of friction with steel and such a fiber over that of steel on steel. This is one of the few clutches running successfully without a lubricant; that is, it is what is known technically as a dry clutch.

It is mounted in the second compartment of the unit case, which may be considered to have three compartments—first, the engine base, or crankcase; second, the clutch; third, the transmission part. These, being constructed as a unit, allow the use of a joint between the clutch and transmission, the desirability of which is granted, but which is prevented in the ordinary construction. This joint consists of a squared end on both the clutch shaft and the main shaft of the transmission, over which is fitted a sleeve with a square hole broached in it.

Numerous Universal Joints Are Used—Not only is a joint used between the clutch and transmission, but two are used in the propeller shaft, one at the forward end and the other at the rear axle. All of the joints are self-lubricating, since they carry a grease cup, or rather a series of grease cups.

The rear bridge is of very simple construction, leaning as it does toward single and complete units. Thus the propeller shaft is square at the forward end for the universal joint, and the rear end has the driving bevel cut integral with it. This shaft is very short and can be removed bodily from the case with very little work.

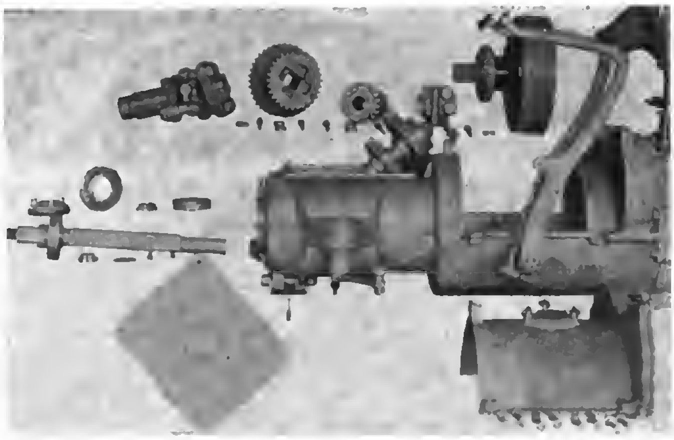
New Steering Connection

Carried on the large driven bevel is the differential, which has a unique cover arrangement, designed for accessibility. The differential case is made with a series of slots or dovetails in its circumference, into which the slots in the cover fit closely, the holding bolts pulling the cover up tight. These holding bolts are, however, separate and distinct from the bolts which retain the differential in the gear, so that the cover may be removed bodily or slid off enough to allow inspection of the interior without disturbing the large bevel or differential.

The axle is of the full floating type, the axle proper consisting of a pair of round shafts with squared inner ends and flanged outer ends. The latter are cut with six slots, which fit over a similar number of identical places in the outer end of the wheel hubs. By removing the hub cap these may be drawn out without using force, and while the car is either standing still or running. Different from the ordinary rear axle is the differential unit construction, this being mounted as a separate unit on special ball bearings arranged to take thrust as well. The bearings should never need adjusting, but if they do it is a simple matter to rotate the two collars provided for that purpose, and the adjustment is made. Differential case, bearings and all may be removed by taking off the upper half of the case and withdrawing the axles enough to allow lifting the unit up. The rear wheels revolve on the stationary axle housing, and are equipped with annular ball bearings at both inner and outer ends of the hub.

Distinctive Steering Gear Construction—Steering is accomplished through the medium of a gear of the worm and sector type, a distinctive feature being the forging of the gear integral with the shaft of the steering post. Another of equal merit is the attachment of the sector to the steering arm by means of a taper square, which never wears out or becomes loose. Adjustment is made through a hardened eccentric bushing.

Platform spring suspension is used on the rear end, the correcting shackles being so designed as to overcome the side roll



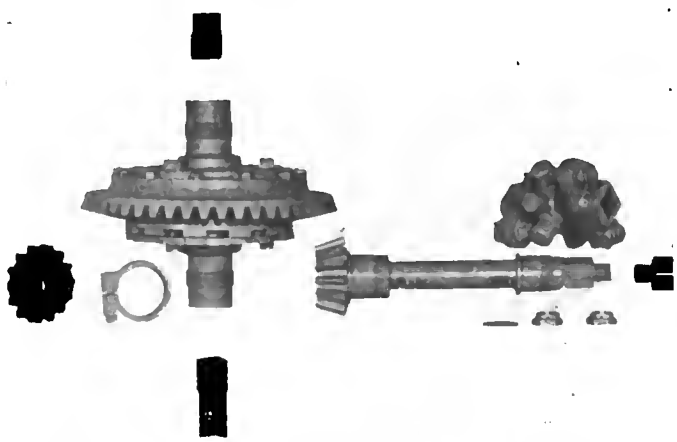
As the Transmission and Clutch Look Dissembled

on curves. Both springs are of special design, which dispenses with the usual binding bolt in the center, a common source of weakness. The forward ends of the springs are attached directly to the frame, but do not take any of the torsional effort of the drive, a torsion rod of large diameter being fitted for this purpose. It is attached to the cross member, which carries the rear pivot of the three-point suspensions by means of a ball joint connection, making a very flexible arrangement. The spring material is special, designed to have the greatest possible elastic limit and strength under compression, while at the same time retaining its flexibility, which makes riding such a pleasure.

The price of the six-cylinder car, Model Y, is $4,000; with top, $150 extra, and tire irons, $25 extra. Models X and XXX both sell for $2,900, but the runabout body is $50 less. For the baby tonneau the top with slip cover is $135, while top for the runabout is but $100 extra.

EJECTOR MUFFLERS ARE VERY PROMISING

In this type of muffler it is the aim to utilize the energy that remains in the exhaust to create a vacuum and aid in the process of cleaning out the exhaust ports of the motor, as well as eliminating noise. Increasing power is one of the advantages sought, and there is no reason why this should be attended by additional noise. The principle involved requires that the flow of gas be directed through a nozzle in such a way that a vacuum will be created in a chamber concentric with and surrounding the muffler chamber proper, the vacuum is due to increasing speed resulting from the use of the nozzle, and the vacuum is filled by gas shunted from the stream that supplies the nozzle, which stream is "baffled" to some extent in its passage. In this way the energy in the gas is expended and the lowering pressure is attended by a reduction in noise: power of the motor increases due to the elimination of back-pressure, and to some extent by virtue of the vacuum.



Stevens-Duryea Differential Case and Universal Joint

STARTING with the startling statement, "The best car in the world has been made better," the announcement of the Winton Motor Carriage Company, Cleveland, O., proceeds to give the details of the car which will be found changed from now on, the 1909 output having been disposed of, so that the factory is now working on the 1910 cars. These include, as mentioned briefly in THE AUTOMOBILE's advance notice, page 72, July 8, a larger clutch, an improved carbureter, a new front axle, longer wheel base and springs, as well as a number of minor and less important changes.

The engine remains unchanged, with six 4 1-2 by 5 inch cylinders, rated at 48.6 horsepower. The cylinders, cast in pairs, with water jacket completely surrounding each individual cylinder, are made of tough, close-grained iron; ground to mirror smoothness, assuring long life, freedom from wear and positive compression. Cylinders are submitted to hydraulic test of 300 pounds per square inch before use.

Offset Feature Retained After Severe Test—Cylinders are offset from the crankshaft, securing from the motor its maximum power efficiency, reducing and equalizing side thrust against cylinder walls, and eliminating the "knock" which always tends toward loosening of parts and premature decay of the motor.

Long connecting rods reduce angularity of operation and long pistons avoid "cocking," decrease wear and friction in cylinders. three snug-fitting, eccentric piston rings on each piston assure good compression and power at all times. All pistons, rings, connecting rods and wrist pins of same weight per set, giving perfect balance. Interchangeable, mechanically operated, two-piece adjustable valves of liberal size, all on one side of the motor, avoiding the use of two camshafts.

The nickel steel used in the valves offers high resistance against the oxidizing and warping effect of hot gases. Due to the valve motion, there is no temporary sluggishness in Winton motors. The profile of the cams is such that it gives a flow of gas proportionate to piston speed.

The crankshaft is made of specially treated nickel steel, having a tensile strength of 125,000 pounds to the square inch. There are four large bearings, bushed with Parsons' white brass. Bearing surfaces are ground. An aluminum crankcase is equipped with three 5 by 8-inch hand-holes to permit instant inspection. The case is divided into right and left halves to provide for ready removal of crankshaft, connecting rods and piston, without disturbing cylinders or motor accessories.

Self-Starter Again Featured—Now that so much talk is going the rounds about starters and starting devices, it is not strange that the starting arrangement which has been so successful on the Winton cars for the past two years is retained and featured. The arrangement of this is as follows: Tubes running from the first and sixth cylinders carry part of the combustion pressure to a storage tank under the body. Here it is stored until required for starting purposes. The driver then opens a push valve on the dash, and the compressed air rushes through a rotary distributor valve to the two cylinders just over dead center. This pressure pushes down these pistons and, on the occurrence of a spark, the motor starts. The entire mechanism has only one moving part—the distributor valve. An attachment on the self-starting equipment permits tires to be inflated without the use of pump.

Assembled on the dash are: (1) the gage, which shows the amount of pressure stored in the tank; (2) the push button, which allows pressure to flow from the tank to the cylinders, and (3) a shut-off valve, for use when the car is to remain long idle, preventing escape of pressure from the storage tank.

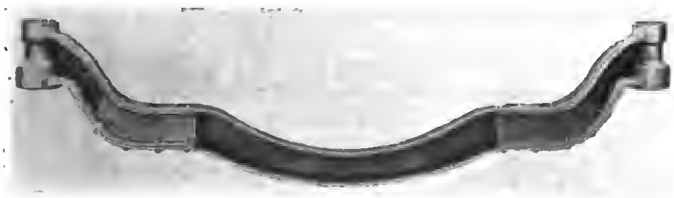
Water circulation is secured by a gear-driven, centrifugal pump, having throw of unusual power. The water is filtered before it passes through pump, making it impossible for water to clog in the radiator or to cease circulation even though pump should become deranged; in that event, water passes through the pump chamber and the circulating system on the thermo-syphon principle. The new design vertical tube radiator is of extra large size, made of copper tubes, with fins. Tubes are lengthened 1 inch. Radiator filler lengthened 1 inch, and has notched hard-rubber cap. Radiator fan is gear driven through friction clutch, securing proper suction of air without possibility of accident to fan or adjacent parts.

Lubrication is force feed, the same as in 1909, and ignition is by Eisemann magneto, with storage battery to supply auxiliary current for starting. The carbureter represents the result of Mr. Winton's long experience in carbureter work. It is of the single-nozzle type, without auxiliary air inlet, and is equipped with two throttles, which work in combination. The carbureter assures economy of fuel and satisfactory operation at all speeds, and obviates the difficulties often encountered at slow motor speed. No automatic air valve. Carbureter is placed on the opposite side of the engine from valves. It is throttled mechanically by lever from steering column or foot button at driver's right foot. Carbureter primer is on the dash.

An oil pump operated by an eccentric on the rear end of the crankshaft takes oil from the oil tank at the left side of motor and delivers it through leaders to the crankshaft main bearings and the front gears. A second pump, operated by the same eccentric, draws oil from the crank case (where it is deposited by gravity), and returns it to the oil tank, whence it passes through a strainer before being used again. No large volume of oil in crank case to drip into pan. Flow of oil is proportionate to motor speed. By-pass regulates quantity. The cylinders are fed by splash. Transmission gears and clutch run in oil and are constantly bathed in lubricant. Oil grooves in cylinders and pistons distribute the oil around their entire surfaces.

Next in Importance Is the Transmission—Probably the details of the gear box will excite more attention than any other one part because of the changes made in it. It is of the selective type, sliding gear transmission, supported on annular ball bearings. There are four forward speeds and reverse. Direct drive is on the third speed, through internal and external gear combination. Lockout on fourth speed. The selective system permits any gear change without passing through any intermediate gears. The gears are of special alloy steel, hardened, and ground to perfect fit. Selective and interlocking mechanism is entirely enclosed in the transmission case, assuring freedom from dirt and allowing proper lubrication. The selective mechanism makes it possible to enter neutral position, but impossible to engage any new set of gears while clutch is engaged.

And the clutch, too, will arouse much interest since it has been enlarged, the number of springs changed and a few minor changes made in it. The multiple disc clutch is tested to hold 90 horsepower at 1,000 revolutions per minute. Of its 67 steel friction surfaces, 33 are attached to the transmission shaft and 34 to the driving spiders, which are connected to the fly wheel, thus observing the mechanical principle that the parts having the least inertia be attached to that part of the mechanism having a variable velocity; as, for instance, when gears are shifted. The clutch discs are 50 per cent. larger in diameter.

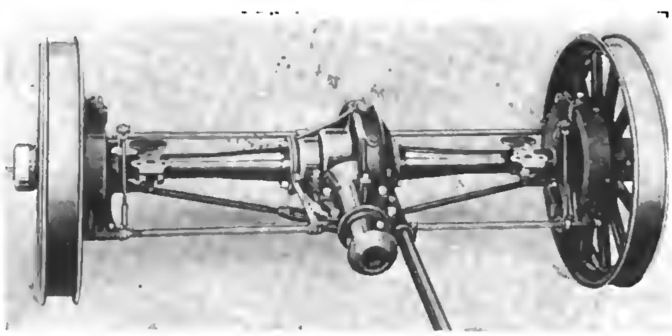


The New Front Axle Is Of Pressed Steel

The discs revolve constantly in an oil bath. This eliminates wear and allows the transmission of the power of the motor to the driving wheels so gradually (owing to its many members, with film of oil between), that shocks to the transmission are unknown. There is no gripping even when starting the car on the third speed. The clutch is carried on annular ball bearings. There is no end thrust on bearings when clutch is engaged. No special lever is necessary to separate the discs when clutch is disengaged. Clutch is contained in the transmission case and is immediately accessible through hand-hole. Four springs, placed at equal distances around the clutch, distribute the tension equally on the discs. Springs are readily removed and replaced. Clutch pedal cannot be locked with the clutch out of engagement, this being a precautionary measure, necessitating neutralizing of gears when car is stopped. Clutch and hand brake are interconnected. The entire clutch mechanism is extremely compact, and the operation of the clutch requires little foot pressure.

Frame Is Narrowed at the Front End Now—Among the incidental improvements is an inswept frame, which permits the car to be turned in short radius. This is all the more desirable now, inasmuch as the wheel base has been lengthened to 124 inches as against 120 inches last year. The additional space thus provided in the body affords the passengers more than ordinary foot room, both in front and back. The body is wider than before, and has a low, rakish look. The low effect has been gained by the use of semi-elliptical springs without scroll. The new car carries four shock absorbers and four rubber bumpers.

The side rails and drop members are of one-piece, channel-section, pressed steel, strengthened at their intersections with heavy gussets of particularly effective design. Motor, clutch and transmission are carried on drop frames. There is no sub-frame.



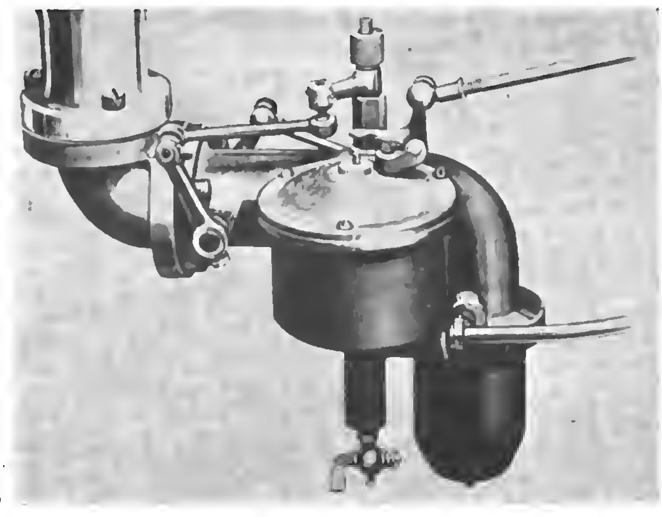
Winton's Rear Axle Construction For 1910

Rear axle is of the full floating type, the axle proper carries no load, but merely transmits the power from pinion shaft to driving wheels, the weight of the car being carried on a heavy drawn steel tube which surrounds the axle. Consequently, it is possible for the axle shafts, differential gears and differential bearings to be removed from the car without the use of jack or pit, car remaining supported by the wheels. Special Timken roller bearings are used throughout. Drop-forging is the process which produces the nickel steel gears and pinions.

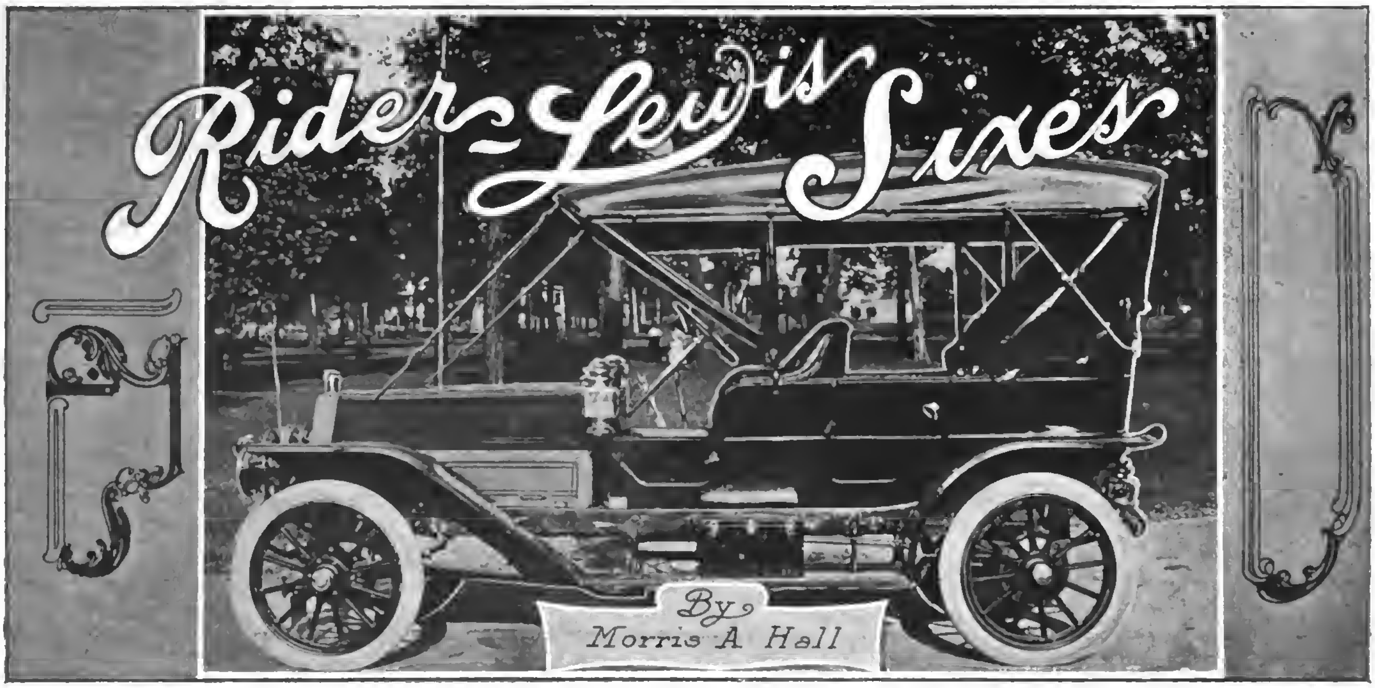
Front Axle Shows a Decided Change—The new car is characterized by a front axle of channel section pressed steel, of a new design, which promises great strength and stability. The central portion (there are three parts to the axle) forms the dropped bed, while the end portions carry the bearings.

At the purchaser's option the car will be fitted with long or short pedals for clutch and brake, and when desired the gear-change and brake levers will be placed nearer the seat than on standard equipment. The radiator is of handsomer design than before, and in making this change the radiator tubes were slightly lengthened, as was also the filler. The filler cap is of hard rubber. Solid brake spiders and increased brake leverage are new features. The oil tank has been enlarged, as has also the front universal joint, which is equipped with a lubricant retainer. There are oil cups on the springs. Running boards and guards are wider than before. Rear guards drop over the wheels. Running boards and front floor are covered with pressed aluminum.

The price remains unchanged at $3,000 for the 48 horsepower Winton Six when equipped with either touring car, runabout or toy tonneau body. When equipped with limousine body the price is $4,250, and with landaulet body, $4,500. For the third successive season the Winton Company will manufacture sixes exclusively. In addition to the 48 horsepower car, there will be a 60 horsepower Winton Six at $4,250, specifications to be announced later. The output of this larger model will be limited.

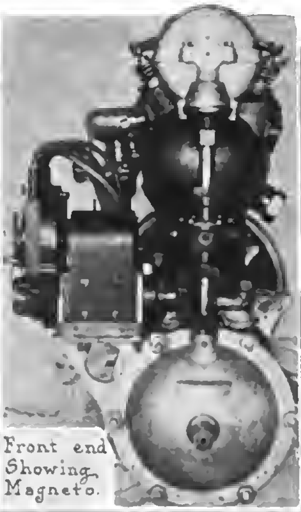


There Is A Double Throttle On The Carbureter

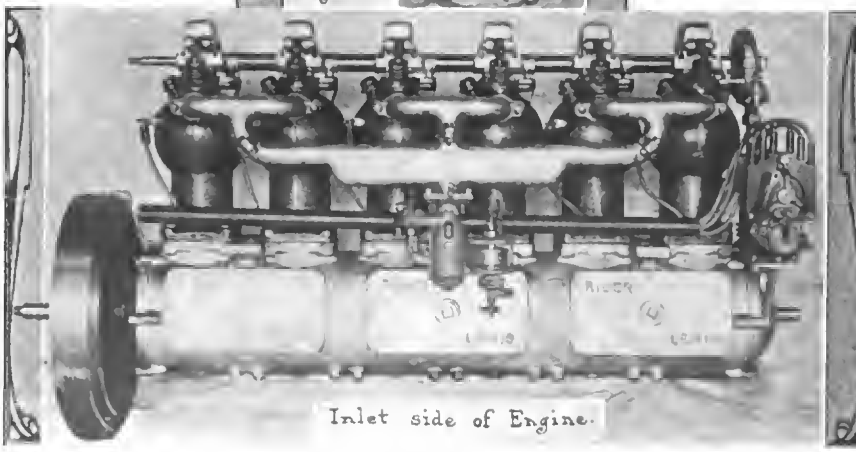


NOW that the question of "sixes" versus "fours" has been settled to the satisfaction of all concerned, it will not be necessary to go into constant torque, regular firing, and all those points upon which the advocates of the "six" delight to enlarge. Suffice, then, to say that the Rider-Lewis Motor Car Company, of Anderson, Ind., in pinning its faith to the six-cylinder motor, is making no mistake. Housed in a large, new and very modern factory, with abundant floor space, contented workmen, and an efficient engineering corps, the company will now proceed to devote all of its energy to turning out a small number of machines, as nearly perfect as human skill can make them.

Motor Shows Individuality—In the engine, probably the most important part, a difference from the ordinary run of cars is noticed at once. This has a number of features not found on any other engine. Thus, the valves are located in the heads, in removable cages. A construction like this allows of the ready removal of the valves for inspection or grinding, and without disturbing any other part. The cylinders of four-inch bore and the same stroke are cast individually. The upper part is given a globular shape to correspond to the spherical combustion chamber, the size being such as to allow of the cooling water being freely circulated around the valve cages. The valves are operated by means of rocker arms, which in turn are actuated from an aluminum-enclosed, overhead camshaft. This is driven from a vertical shaft at the front end of the motor, with a bevel drive from the crankshaft and driving the overhead shaft in a similar manner. Pistons are fitted with four rings, three at the top and one about the middle of the piston, the latter being used to retain the piston pin from lateral movement.



Front end Showing Magneto.



Inlet side of Engine.

By means of four large-sized bolts, the cylinders are fixed to the upper surface of the aluminum crankcase. This is in one piece of the now popular barrel type, the crankshaft being entered from the ends, which are closed by means of a pair of circular plates. White brass bearings are used in these plates and in the crankcase bearings, five in number, making seven in all. In the connecting rod and camshaft bearings, phosphor bronze is used.

Aluminum Used Freely—The inlet pipe is of cast aluminum, in three pieces, bolted together and to the cylinders. The carbureter is located midway of that side of the engine, and rather high up as carbureter location goes. The exhaust pipe, on the other hand, consists of six separate pipes, set slightly out of a vertical, brazed to a horizontal header. The latter is of unusually large diameter, in order to eliminate all back pressure. Water is piped to and from the cylinders in a manner differing from both the inlet and exhaust piping. Into each cylinder, at the rear, top, central part and the left, under side of the hemispherical cylinder dome is screwed a fitting. To this is screwed a union. The inlet and outlet pipes, *per se*, are castings of a tapered section, threaded at the seven extremities. To connect the castings with the cylinders, a short bent pipe of brass with a union connection at each end is used.

Ignition is single. high tension being used. with a Bosch magneto as the source of current. This is located in front and is set across the engine, being driven from the vertical shaft through bevel gears. If it should be desired, double ignition can be had at practically no extra expense, because the rear extremity of the overhead camshaft is arranged to take any standard timer. The magneto position allows of very simple wiring.

Transmission and Rear Axle Form a Unit—Conforming to the practice of placing the transmission on the rear axle, even in this originality is shown. The dead weight is kept down as low as is consistent with strength by the use of an aluminum case. This, considering the differential housing as an integral part, is in three sections. The forward one is but a hand hole to allow the entrance of the gears. The central portion has the left half made separate for the same purpose, namely, the admission of the axles and differential. All three are liberally ribbed to give strength. Hand holes are provided in the forward portion for the inspection of the gearing, while the rearward part has a pair of oil holes, which are so large that one can see the gears through them.

The transmission is of the sliding type, operating on the selective principle. and furnishes three speeds. All gears are of chrome nickel steel, on chrome nickel shafts, which are mounted

Rear Axle and Transmission Unit Is Distinctive

upon roller bearings. The torque reaction is taken by a long stiff rod of circular section. This is fastened to the frame at its forward end by a ball joint.

Old and reliable describes the clutch, which is of the cone type, faced with leather. It is operated directly from the pedal shaft, one of the only two shafts crossing the chassis, by levers with rollers which press against a large collar. Although the spring is inclosed, the construction is such as to allow of easy adjustment from the outside. Directly back of this is placed the only universal joint used.

Front axles on the Rider-Lewis sixes are I-section forgings of large section, the material being steel. The pivots are of the Elliott type, and to their design much care has been given so as to insure safety at this important point.

C Type of Rear Spring Makes Riding Easy—The spring suspension is equally good, semi-elliptic being used in front, while in the rear, superior riding qualities are obtained by the use of the C type of spring. In the use of this, the lower leaf is rigidly attached to the frame after the best semi-elliptic prac-

Straight Line Touring Body on Four-Cylinder Chassis

tice. The size of the front springs is 36 by 2 inches, and of the rears, 38 by 2 inches with eight leaves. Both springs are banded. The frame is of pressed steel, to which is riveted the brace and tie members. This is dropped at the rear for a low center of gravity and narrowed in front to allow of a large steering lock. Steering is effected by an irreversible gear of the screw and nut variety. This has a horizontal fore and aft connection to the cross steering rod, placed in front of the axle.

Two markedly different bodies are fitted, the full touring shown in the heading of this article being known as Type VIII. For the runabout body, the construction is altered somewhat to provide more rake in the steering post. This and other minor changes make it somewhat different from the touring car, so a different model number is given it, Type IX. The price, however, is the same for both, $2,500.

And a Good-Looking Little Car, Too—In addition to the full line of sixes, an excellent little car, to sell at a popular price, has recently been added to the factory output. This has a four-cylinder engine of 4-inch bore and 4½-inch stroke, rated at 30 horsepower. In this, however, the four cylinders are cast in a block. The crankshaft has but three bearings. Cooling is by thermosyphon, and oiling is self-contained. This car is built to be of an unusually light weight, the weight ready for the road being less than 1,800 pounds. As this gives a very low ratio of weight to power, less than 60 pounds, the car is very powerful either on hills or speeding. The light weight is obtained in part by the elimination of needless parts, thus there is but one cross member in the frame.

One big feature of this little car, which is bound to make it popular is the fact that it is equipped with a three speed sliding gear transmission, which operates on the selective principle. The use of a block motor gives a very short hood, which, in turn, gives the greater part of the long wheelbase space to the body and in this way allows it to be more roomy and comfortable. The wheelbase is 100 inches and the wheel sizes 32 inches. To these are fitted 2½-inch tires, large enough for the light weight.

Selling at an even $1,000, this chassis is equipped with a touring body of the straight line type. This resembles the roadster body fitted to the six-cylinder chassis, except for the tonneau in place of the bucket seat of the latter.

Modern Factory of Rider-Lewis Motor Car Company at Anderson, Ind., as It Appeared Just Before Completion

HOUPT CAR MAKES ITS METROPOLITAN DEBUT

THE first of the new Houpt cars returned to the factory at Bristol, Conn., after an 800-mile test trip with Montague Roberts at the wheel, and the makers are well satisfied with its performance. For the last month the car has been traveling over some of the roughest roads in New England, New York and Pennsylvania, yet Roberts declares that he did not once open his tool kit after leaving the factory. This car is of the four-cylinder, 60-horsepower type; the six-cylinder model also planned by the Houpt Company will not make its appearance for another month yet. However, the Houpt Company promises to have at least three of the four-cylinder cars in New York by August 1, and will enter a team for the coming 24-hour race at Brighton Beach. One of the entries will be driven by George Robertson, last year's Vanderbilt winner.

Montague Roberts at the Wheel of the New 60-Horsepower Houpt

The Houpt car is thought to be the largest four-cyclinder stock car made in this country; its cylinders are 5 1-2 inches bore by 6 inches stroke, rated at 60 horsepower. The cylinders are cast in pairs, and the valves, 2 5-8 inches in diameter, are placed on opposite sides. In general the motor follows standard design. In the tests at Bristol, the motor showed exceptional power and quick acceleration, combined with practically noiseless operation. The carbureter is float-feed, the gasoline being under pressure in a tank slung from the rear of the frame. The water-cooling system employs a centrifugal pump with both radiator and flywheel fans. The ignition is double, with a single set of spark plugs in the cylinder heads.

Power is transmitted through a multiple-disc clutch containing 53 steel-on-steel discs, and the change-gear is of the selective type, giving four speeds and reverse. Drive is by a nickel-steel cardan shaft to a full floating type of live rear axle, with bevel differential. The frame, also of nickel steel, is dropped forward of the rear axle and rests on semi-elliptic springs both front and rear. The motor suspension is four-point and that of the gear case three-point. Brakes are internal expanding on the rear hubs and external contracting behind the gear case. The wheelbase of the four-cylinder car is 127 inches; wheels are 36 inches, with 4-inch tires in front and 5-inch in rear. The car weighs 3,100 pounds. In the illustration the car is shown fitted with a testing body; purchasers. however, will have the choice of seven different styles.

The six-cylinder model now under way will have cylinders of the same size as the four—that is, 5 1-2 by 6 inches; and its power will be conservatively expressed by the maker's rating of 90 horsepower. Its specifications are identical with those of the four except as to dimensions. The wheelbase will be 140 inches and the weight 3,900 pounds. In addition to the Houpt cars, the Houpt Company in New York City will continue to act as distributor of the Herreshoff, as the two lines in no way conflict with each other.

Although the design of the Houpt is in direct opposition to the present tendency toward smaller cylinder sizes, its makers believe that there are plenty of automobilists in the metropolitan district who will welcome a car of racing proportions.

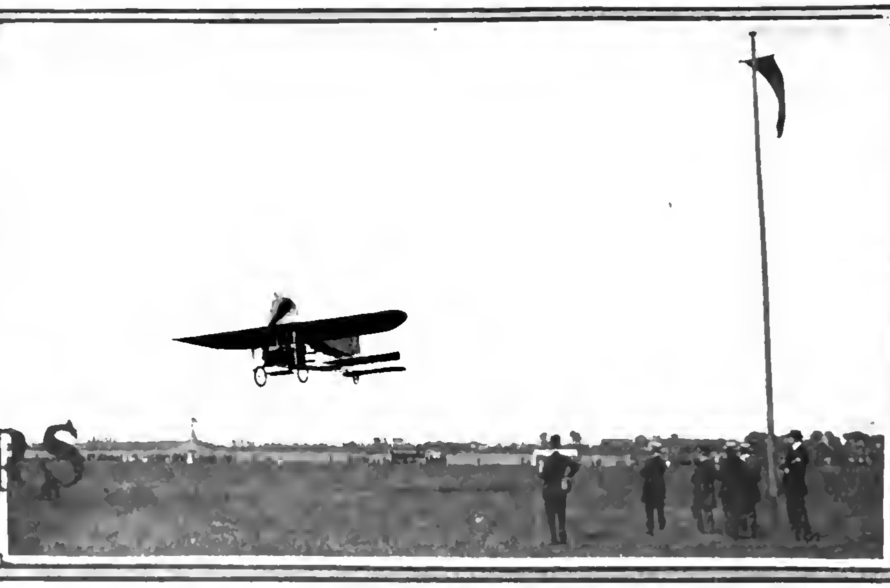
DETAILS OF THE 1910 FRANKLIN MOTOR

The new Franklin motor, like all its predecessors, is air-cooled, but the method of applying the current of cooling air is radically different and completely changes its exterior appearance. Encircling the motor on the level of the chassis frame is a sheet-metal deck with funnel-like casings which encircle each cylinder and tightly embrace their vertical cooling fins. Underneath the motor is the usual mud-pan, but this, in connection with the upper sheet-metal deck, forms an air compartment whose only openings are those of the cylinder funnels. At the rear of the compartment is the flywheel, containing a powerful suction fan which draws a current of air through the funnels. By this system the air currents arc downward, striking first the hottest parts—the tops of the cylinders and the valves—then passing along the cylinders and out through the flywheel. The familiar Franklin features of the auxiliary exhaust, the concentric inlet and exhaust valves and the dome-headed cylinder, are still retained. The usual fan in front of the motor is dispensed with, and this, together with the smooth funnels encircling the cylinders, gives a very simple and neat appearance.

ABOUT PRESSURE FEED GASOLINE TANKS

Considering the difficulty involved in connection with gravity feed fuel tanks, if they are of considerable depth—thus requiring that account be taken of the resultant changing pressure due to the difference in "head"—the usual practice, in the process of avoiding such changes in pressure, is to use pressure from the combustion chamber of one cylinder of the motor, passing the same through a reducing valve, the function of which is to take the uneven wave of pressure from the source and level it down, as well as reducing the pressure per square inch to that agreeable to the requirements, which should not exceed the amount which will assure that the gasoline will positively flow to the carbureter, even with some jelly formation in the system. A difference of pressure equal to 30 inches of water ($0.0358 \times 30 = 1.074$ pounds per square inch) should be adequate for the purpose, even taking into account a considerable gradient of the road, and the car so designed that the gasoline would have to flow up grade one-half of the 30 inches above noted. Since a grade of fifteen inches in the ordinary 120-inch wheel base is seldom met, this is safe practice.

Latest Doings of the Air Navigators



Bleriot Making Successful Flight at Juvisy, In Which He Came Dangerously Near Breaking Monoplane Record

PARIS, July 13—Louis Bleriot, the French monoplane champion, narrowly missed establishing a world's record Sunday July 4, during a magnificent flight with his No. XI, at Juvisy, near Paris. He remained in the air for 50 minutes 8 seconds, being forced to descend because he was blinded with the splashing of oil from his engine. The longest flight ever made on a monoplane type of machine is 1 hour 7 minutes, accomplished by Hubert Latham.

The Bleriot performance was accomplished with a comparatively small machine driven by an Anzani three-cylinder, air-cooled motor of 25 horsepower. In order to assist in cooling, the engine is fitted with auxiliary exhaust ports at the end of the stroke. Whenever there is a slight excess of lubrication, the oil is forced through these holes into the face of the pilot, placed immediately behind the engine. On more than one occasion a flight has been stopped by this reason alone.

Louis Bleriot has also the intention of making a record cross-country flight of not less than 25 miles. His machine was this week taken down to Etampes in readiness for the flight, but owing to a gale of wind and rain no flight could be attempted. The apparatus was left on the spot, and will be brought out in a few days. The flight is the most ambitious one across country yet attempted, for although the country is fairly flat there are serious obstacles in lines of poplar trees rising to a height of 65 feet, the railroad and telegraph wires. Starting from near Etampes, the aeroplane will make almost directly for the town of Orleans, the descent to be made three or four miles from the city limits. The machine to be used for this flight is the monoplane No. XI, equipped with the three-cylinder Anzani motor.

LATHAM FLIES HALF ACROSS THE CHANNEL

CALAIS, FRANCE, July 19—Hubert Latham made a gallant attempt to cross the channel with his Antoinette monoplane to-day, but was forced to come down with his task but half accomplished on account of the failure of the motor. He was picked up by a torpedo boat, along with his machine, and carried back little the worse for the experience.

Latham has been at Calais for over a week, making practice flights and watching for a favorable opportunity. Yesterday a stiff breeze, which had been blowing all day, subsided at sunset, and in anticipation of an early start, Latham slept in the aeroplane shed at the edge of the cliff looking over the Channel. At the first streak of dawn all turned out. The sea was smooth and the wind, a mere breath. The authorities at Calais had been notified, and a torpedo boat detailed to follow the flight waited at the foot of the cliff. Several thousand persons had assembled when the aeroplane was wheeled from its shed and brought to the starting point. Latham made a careful inspection and tested the motor, which worked perfectly. He wore a life preserver.

When all was in readiness he mounted; the motor was started, and with a farewell cry of, "See you in Dover" he swept to the edge of the cliff, tilted the elevation plane and the machine sailed gracefully out over the water. It mounted gradually to a height of about 300 feet and continued its course steadily toward the English shore, at the rate of about thirty-five miles an hour.

Twelve miles, over half the distance, had been covered when the motor began to slow down. Latham found his attempt was hopeless and gradually sank down to the water, in a smooth, even glide, alighting with hardly a splash. The air entrapped under the curved wings kept the machine afloat. and Latham kept his seat, putting his feet up on a cross-bar, and lighted a cigarette. The torpedo boat, which had been steaming at top speed, soon caught up and he was rescued from his perilous position. On the return to Calais an enthusiastic crowd waited on the wharf to cheer him.

Latham said that he thought he was fully a thousand feet in the air when his motive power gave out, so that even though his attempt failed he can claim to have established a record for altitude. The best previous record was 450 feet, established by M. Paulham with a Wright aeroplane. The machine was but slightly damaged, most of the injuries being incidental to hauling it aboard the torpedo boat. Latham left for Paris to-night, saying that he would be back in a week or ten days to try again.

LAMBERT MAY TRY CHANNEL FLIGHT

WISSANS, FRANCE, July 19—Count de Lambert, one of Wilbur Wright's pupils, has brought two Wright aeroplanes here and is preparing to make a series of flights. It is believed that he may make an attempt to cross the Channel before Latham can get ready again. If he succeeds it will secure great prestige for the Wright machine, which has been rather overshadowed by the feats of the Antoinette monoplane type.

PAULHAM MAKES CROSS-COUNTRY FLIGHT

ARRAS, FRANCE, July 19—M. Paulham, who has been making many short flights near here with his Wright aeroplane, to-day flew across the fields from this town to Douai, covering the twenty kilometers (about twelve and a half miles) in twenty-two minutes. He attempted to return, but after going three kilometers was forced to descend by the rising wind. In the landing his rudder was broken.

ORVILLE WRIGHT MAKES SEVERAL SUCCESSFUL FLIGHTS

WASHINGTON, D. C., July 20—The Wright brothers seem to have shaken off the hoodoo that has been so much in evidence recently. The tumble July 14, when one of the skids was broken—the third accident of the present trials, by the way—was its last manifestation, and everybody at Fort Myer hopes that it has gone to stay. Contrary winds and rain storms prevented any trials on the two following days, but the brothers spent the time in altering the starting apparatus. They added about sixty pounds to the weight which gives the initial momentum, dug a pit a foot deep to give it a longer fall, and lengthened the starting rail by about 12 feet.

Saturday saw the first trial of the remodeled mechanism, and it was greatly encouraging. After one short flight the length of the field, which was stopped to avoid a collision with the balloon house, Orville Wright got away in good shape. This time he cleared the house by fifteen feet, and maintaining the inclination of his forward plane he soon soared over the spectators at a height of 100 feet. He made about sixteen circuits of the field, but did not follow any regular course. On several occasions he made wide excursions out over the wooded country behind the balloon house, and seemed to delight in sailing over the cavalry stables and over the tall chimney of the post's power house. Apparently he wishes to accustom himself to soaring over rough and broken ground, as he will have to do in the official trials. The landing was made without the least jar, and stop-watches caught the time at 16 minutes 54 seconds. His speed was estimated at 40 miles an hour.

This flight, however, was far surpassed on Monday, when the aeroplane covered about forty miles altogether. The Wrights ordered the machine from its shed about 6 P.M., after the breeze that had blown all day had died away. They worked some minutes over the motor, and then Orville took his seat and shot away. After several smooth rounds of the field at an elevation of about eighy feet, just to get the feel of it, he began to put the machine through its paces. First he swooped down close to the earth, then rose steadily to about a hundred and twenty-five feet, and made several more rounds. Then he ascended still higher, and at the same time narrowed his circles, with the rudder held steadily to port. The sun had set, but the aeroplane was still full in its rays. Finally Wilbur, who had stood watching, watch in hand, waved his hat as a signal, and Orville swept gracefully down to earth. The flight lasted 25 minutes 18 seconds.

The aeroplane was immediately carried back to the starting point, and after the motor had cooled off it was again started. Soon it was describing great circles at nearly 150 feet elevation. For a while the motor ran irregularly; the skipping of its explosions could be heard plainly. Still the flight continued. In the gathering darkness the machine was often completely lost to sight, only becoming visible as it tilted on the turns. When the planes presented only their thin edges they were completely invisible. This fact especially pleased the officers of the Signal corps, as it demonstrated a great advantage of the use of the machine for scouting and carrying dispatches. It was after eight o'clock when Orville decided to come down. He chose his landing place with great care, swooping down and then ascending several times. He finally descended within a few feet of the shed, after a flight of exactly thirty minutes.

WRIGHT MAKES NEW AMERICAN RECORD

WASHINGTON, D. C., July 21—In a spectacular flight late yesterday evening Orville Wright estalished a new American record by remaining in the air one hour 20 minutes and 45 seconds. The aeroplane made sixty or seventy circuits of the field, interspersed with several figure 8's, and at times attained a height of 300 feet. Some of the circles were so short that the flier seemed to be turning almost within its own length. The motor worked perfectly.

CURTISS AEROPLANE WRECKED BY NOVICE OPERATOR

AFTER a magnificent flight of nearly an hour, placing him easily second to Wright brothers in this country, Gleen H. Curtiss saw his aeroplane wrecked on the grounds of Mineola, L. I., last Sunday by one of the two men whom he was teaching to operate it, in accordance with his agreement with the Aeronautic Society. His pupil, Alexander Williams, lies in the hospital with a broken arm. Although Mr. Curtiss took the train for his factory at Hammondsport, N. Y., immediately after the accident to secure repair material, he will be unable to continue his flights before next week.

The aeroplane was to have been delivered to the Aeronautic Society this week. One of the conditions of its sale was that Curtiss should teach two members of the society to operate it. The two selected were Mr. Williams, who became known through his attempt to build an aeroplane of his own at Morris Park, and Charles F. Willard, a young automobile engineer who has an office at 1777 Broadway, New York. Sunday morning the two met on the grounds for their first lesson. Mr. Curtiss first made a short flight of 7 minutes 40 seconds in perfect form, rising to a height of 150 feet and describing circles and figures 8s.

After this preliminary the two pupils flipped a coin and Willard won. He mounted the seat of the aeroplane and started across the field. The machine soon rose easily into the air and sailed along steadily at an elevation of 10 to 15 feet. After covering about 500 feet Willard slowed down and touched the ground for a moment, then rising again continued for about 200 feet more. Mr. Curtiss was delighted and declared that it was better than his own first flight.

After the machine had been brought back to the starting place Williams climbed into the seat. Apparently trying to imitate Curtiss' previous flight, he at once tilted the front plane to a sharp angle and lifted the machine to a height of 40 or 50 feet. Then he turned the steering wheel full over and sent it sharply to the right. The sudden twist tilted the planes over at an angle of 45 degrees. Then Williams lost his head completely and was unable either to straighten out or to shift the balance planes to regain an even keel. After a few spasmodic movements the framework of the machine seemed to give way under the strain and the whole fabric shot down to the ground, the motor still crackling steadily.

Williams was pulled from the wreckage unconscious, but it was soon found that he had suffered only a broken arm and thumb. The machine was carried back to its tent. It was badly smashed, but the motor, fortunately, escaped uninjured.

Mr. Curtiss began his trials at Mineola July 13, making three short flights. Wednesday, July 14, he flew about five miles in seven minutes. Thursday was foggy and he made only two short flights. The next day, however, he circled the field ten times, covering about 15 miles in 22 minutes 20 seconds, and Saturday, in the presence of 3,000 spectators, he made the best flight that has been seen in America this year. It lasted 52 minutes 30 seconds, and it is estimated that he covered about 30 miles in his 19 circuits of the grounds. This flight qualified Curtiss for the Scientific American trophy, which he at present holds.

In the international aeroplane race at Rheims, France, August 28. Mr. Curtiss with his American-built machine will match his skill against the leading aviators of Europe.

MASSACHUSETTS LAW DOES NOT SUPERSEDE TRAFFIC RULES

BOSTON, July 16—In the first test that has been made of the rights of automobilists under the new automobile law that went into effect July 1, the court to-day decided against the motorist. One of the questions that arose immediately after the law became effective was whether it repealed the Boston street traffic regulations so far as they relate to motor vehicles. These regulations contain various restrictions as to vehicles in general: that they shall go only one way in certain streets, that they shall stop only in certain places and for a limited period of time, that they must keep to the right, etc.

Section 17 of the automobile law provides that "No ordinance, by-law or regulation now in force in any city or town or in any park or upon its ways which regulates the speed at which motor vehicles shall be run upon its ways or which excludes such vehicles therefrom or which governs or restricts the use of such vehicles shall hereafter have any force or effect." Believing, he claims, that this part of the law annulled the street traffic regulations Samuel D. Fisher, of Cambridge, attempted to drive in the wrong direction in State street, was arrested, and his case came up to-day in the municipal court before Judge Parmenter.

In the trial, counsel for the defendant contended that there was no rule in effect, as the traffic rule had been annulled by the automobile law. Counsel for the city held that it was the intent of the Legislature in the section in question to do away only with regulations relating to automobiles, and that the traffic rules, which govern the use of the streets by all vehicles, are not within the classification referred to in the automobile law. In announcing his decision Judge Parmenter said: "It seems to me that the best interpretation of this statute is that it repeals only such special regulations as relate to the use of automobiles and does not repeal general traffic regulations." The case will be carried to the upper court.

The new Boston park auto rules have been approved by the Highway Commission. They exclude autos from some park roads and state what roadways shall be used in certain parts of the park system, but contain no speed limits.

THIRTY-ONE STATES NOW IN A. A. A.

While the A. A. A. officials and directors were in Detroit a week ago to witness the start of the Glidden Tour its membership was increased at the monthly meeting of the executive committee by the election of the Wyoming State Automobile Association, making the thirty-first affiliated state body in the National organization. President Lewis R. Speare, of Boston; Secretary Frederick H. Elliott and several other officials returned last week and expressed themselves as highly gratified at the enthusiasm displayed in the A. A. A.'s good roads movement, including the plans for the coming convention in Cleveland and the National Stock Car races to be held in Lowell, Mass., on Labor Day. At the meeting of the executive committee the membership of the good roads board was increased by the election of James R. Jackson, of Grand Rapids, Mich., and Col. W. D. Sohier, of the Mass. State highway commission.

President Lewis R. Speare, of Boston, presided at the meeting, there being in attendance Third Vice-President Frank M. Joyce, of Minneapolis, Minn.; George C. Diehl, of Buffalo, chairman of Good Roads Board; W. W. Brown, president of Automobile Club of Vermont; C. L. Bonifield, president of Automobile Club of Cincinnati; J. O. Heinze, president of Lowell (Mass.) Automobile Club; Percy F. Black, president of Montgomery (Ala.) Automobile Association; Edwin S. George, ex-president Michigan State Automobile Association; A. G. Batchelder, of New York, and Frederick H. Elliott, of New York, secretary.

MILWAUKEE CONTEMPLATES AN ORDINANCE

MILWAUKEE, WIS., July 19—The Common Council of this city is working on an ordinance designed to supplement the State laws regulating automobiles. One of the regulations proposed is that cars come to a full stop when a street car ahead stops to receive or discharge passengers, and another is to establish a speed limit of eight miles an hour in the downtown district. Members of the Milwaukee Automobile Club will watch developments carefully, as there are a number of Councilmen who have no love for automobiles.

WISCONSINITES SLOW IN RE-REGISTERING

MADISON, WIS., July 19—The Wisconsin Secretary of State reports that only a small percentage of owners have complied with the new registration law increasing the fee to $2 at this time. However, penalties will not be exacted until 90 days after the publication of the law, June 19.

REGISTRATIONS INCREASING IN OHIO

COLUMBUS, O., July 17—By the report of the State registrar of automobiles, Fred H. Caley, the receipts of the department for the month ending June 15 amounted to $21,129. The total receipts since the State automobile law became operative have been $120,-101.23. During the month, new registrations issued numbered 1,775 and manufacturers and dealers to the number of 25 were registered. Chauffeurs' licenses issued numbered 65. Renewals of registration numbered 2,175 and renewals of dealers and manufacturers numbered 48.

State Registrar Fred H. Caley has announced that the system in vogue in Pennsylvania of distributing numbers will be followed in Ohio next year. The system provides that numbers will be distributed in the order of the receipt of the application and no attention will be paid to requests for freak numbers, numbers corresponding to the date of birth, marriage, etc. But an exception is made that all applications received previous to December 1 will have the privilege of reserving the present year's number for 1910.

NEW NUTMEG LAW UP TO GOVERNOR

HARTFORD, CONN., July 19—As yet the protests of the circular letter issued by the Connecticut Automobile Association against the new automobile law seem to have no direct effect. The much-talked-of measure has reached the stage where the signature of the chief executive will make or break it and all are wondering just what the governor will do about it. It is a common impression that a veto would be overturned, for the Legislature has put in a lot of time on the measure. However, no one would mind it at all if the 1907 measure were to live another two years.

HEAVY JULY REGISTRATION IN INDIANA

Figures published by the Secretary of State of Indiana show that in the three months from April 1 to July 1 there were 2,591 automobile licenses issued during that time, and during the first eight days of July 249 licenses were issued, an average of 31 a day. A very large number of machines are being sold to farmers, especially to those who have retired from active farm work and moved into towns.

HARTFORD CLUB ISSUES YEAR BOOK

HARTFORD, CONN., July 12—The year book of the Automobile Club of Hartford has just been issued by Secretary A. G. Hinckley. It contains a fund of information, including the constitution and by-laws of the organization, its membership list, etc.

INTERNATIONAL TOURING RECIPROCITY

Should the proposal to have all the countries of Europe join in a plan of international licensing really be carried out, the broadening influence of automobile traffic will have scored a remarkable triumph. Yet it is no mean triumph that such a thing should ever have been proposed. The officials of France and Germany are commonly supposed to be so bound, wreathed and entangled in red tape as to have long ago lost all power of acting or even thinking for themselves. However, a German official politely suggests to a French official that a simple little agreement of reciprocity would be mutually advantageous, and as France is the leader in the automobile industry, would France be pleased to make the suggestion to other countries? And the French official courteously replies that he will consider the matter; and he does consider it, to such good effect that it really seems as if such an agreement might be made.

Briefly, the proposal is that all European countries shall recognize each other's driving licenses and registrations, and that they shall recognize each other's customs' deposit certificates, provided the amount of the deposit is sufficient to cover the duty in the country in question. Thus an American tourist landing in England or France could pass one examination, receive one license tag, pay one customs deposit, and then proceed to travel anywhere in Europe without further inconvenience or red tape. Only one who has tried touring on the present plan can appreciate the immense amount of inconvenience and red tape now required at each frontier.

The countries of Europe have different languages, different tariff laws and different rulers. Our States have the same language, the same ruler and no tariffs to contend with. If Europe can have international licensing, why cannot we have interstate licensing? Governor Fort of New Jersey, who is rapidly redeeming that State's reputation, suggested a reciprocity agreement between Pennsylvania, New Jersey, New York and the New England States. As a starting wedge, the proposal is excellent, and its fulfillment would be an inestimable boon to all the automobilists of those States, not to mention their other inhabitants. Such a movement, too, would doubtless spread to other States until all that possessed any considerable number of automobiles would be included. But the reciprocity should not be dependent on the whim of an often prejudiced and partisan State legislature. What this country needs and must have is a national registration law.

REMEDIES FOR SKIDDING OR SIDE SLIP

In the rush of quantity production, the American manufacturer has little or no time to develop new ideas in automobile construction, hence it has come about that the cars on this side of the water carry with them little of that originality which is so prized on the other side.

As a single instance illustrating the point, the English constructors are now much agitated over the matter of side slip, or, as it is more usually called, skidding. In search for a preventive for this, a number of devices have been developed which seem to merit more than passing attention. Some experimentation was done with tires having a surface calculated to offset the slippery nature of pavements, but the only result of this was to develop the so-called Liversidge tire for heavy trucks.

Another scheme took into account the fact that side slip did not take place at all times but only occasionally. This, then, opened up a field for a device which could be brought into play at the driver's own time and was normally out of engagement. Since the slipping never takes place except under conditions which may be predetermined, it is both feasible and reasonable. This form worked out in the Newcomb attachment, which is attached to the rear axle and by means of a lever at the driver's side is dropped down into contact with the pavement or road surface by a simple movement of the hand.

Still beyond this, were the possibilities opened up by front driving. As against this solution, the fact looms up large that this does introduce many mechanical complications which are objectionable, in fact in the ordinary case more so than the skidding, since the complicated construction is always present, the side slip, very seldom.

This then was not a favored solution, and once more investigators turned away. Next and latest in point of actual construction is the matter of front brakes. These have been taken up, not by one or two builders, but by a large number, including many of the most prominent firms. The recognition of this form of a preventive by the larger firms following close upon extensive tests, leads one to think that there must be a good deal in it. The outcome of much agitation in this direction was a car especially built to overcome the objectionable feature.

REEVES PREDICTS WONDERFUL BUSINESS YEAR IN 1910

THAT automobiles are standard and that few changes will be made in the models for 1910, is the statement made by Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, on his return to New York at the end of last week from the last of three trips occupying about six weeks, that took him into sixty-one of America's leading motor car factories. He repeats his recent estimate of at least 200,000 as the 1910 production, and says that while there will be no reduction in the price of the standard models, there will be more given in a car next year than ever before. In other words, while the price of materials has been advancing, the cost of manufacture is being reduced and the makers are making refinements that will bring out better cars without advancing prices.

A general review of the plans in automobiles for 1910 would indicate that improvements for next year will be confined almost entirely to the refinement of the present successful types. In the opinion of Mr. Reeves, the time which has long been wished for when motor cars would be standard has about arrived.

"In a general way," said Mr. Reeves, "I would say that the 1910 motor car will show a decided tendency toward standardization. The wonderful advances in gas engines during the past ten years has brought the present type of automobile almost to the perfection point, and improvements now must be almost entirely in the matter of details. While there will be some changes of models and designs by a few makers, the inclination is to improve on the present satisfactory type of motor. The future may see some radical changes in car construction, but certainly not for a couple of years. The 1910 car will see those refinements which make for silence and simplicity in operation, increased power without increasing the size of motors, more pleasing design, greater riding comfort and lower maintenance cost.

"One of the most important changes will be the use of a longer stroke in motors. A number of makers are using the same size of cylinder whether they be for a four or six model, which makes for standardization. Magnetos are now in universal use, some makers not even supplying a battery. High-tension and low-tension magnetos are used, each having its followers.

"Among other changes for next year will be larger wheels and tires, a longer wheelbase, especially in the moderate priced cars; the casting of cylinders in pairs and sometimes en bloc; the use of shaft drive, except on a small number of very large cars or buggyabouts; the increasing use of the thermo-syphon system of cooling, and the adoption of a direct drive on third speed in transmissions where four speeds are supplied.

"Most radical of all in the way of changes relates to the placing of the steering wheel on the left-hand side, which will be followed by two of the biggest producers next year and a number of smaller ones.

"In some cases motors are being cast with the exhaust pipe included. One maker will have only one pipe running from the carbureter to the motor, doing away with the manifold. Carbureters have been refined and studied with a view of securing more power and greater distance than heretofore.

"The design of bodies will be given more attention next year and the lines of the cars generally will be more pleasing to the eye. The use of ball or roller bearings is universal. While the four-cylinder motor continues to be the most popular, a number of big cars, and especially those of high power, will be equipped with six-cylinder motors. While a number of the small makers have given up the six-cylinder idea, there has been an increased demand for six-cylinder cars among the big car makers, especially those who turn out the high priced machines.

"It is a revelation to visit those factories which constitute the membership of the American Motor Car Manufacturers' Association, to see the plans, the preparations, the new buildings and the many other things that not alone indicate a great production, but a confidence in the business and the buying ability of the American public, which should result in a record year in 1910.

"While in the West I traveled a couple of days with the Glidden tourists, and I believe that the car which evolves a winner of that strenuous test can truthfully be called the champion touring car of America. A trip each day of from 150 to 200 miles over good, bad and very bad roads, at an average speed of close to twenty miles an hour, requires a car of more than ordinary quality to stand the pommeling. The tightening of a nut or the tying up of a broken fender involves a penalty which kills a perfect score, the gaining of which is the ambition of everyone. Cars that make even a fair showing in that test must be considered by the American public as well worth buying.

"As the hub of the automobile industry, Detroit certainly did itself proud in the line of entertaining the Glidden tourists. They were open-hearted in their care and reception of all who visited the city to see the start, and certainly the Dealers' Association, its officers and the automobile people in Detroit generally have set an example in the line of whole-soul entertaining that may be the aim in future motor events."

On the last of his three trips to the factories comprising the membership of the American Motor Car Manufacturers' Association, Mr. Reeves visited the concerns in Michigan and Wisconsin, which completed his round of the companies holding membership in the big organization of makers. More than sixty factories were included in his six weeks of travel. In speaking of his trip, Mr. Reeves said:

While I expected to see a whirl of industry at the Ford plant in Detroit, I was not prepared for the great work which the big organization there is doing. So busy have they been turning out cars that no effort has been made to move into the new plant on Woodward avenue, and it is believed now that an entire new equipment will be put into that place instead of moving anything from the old factory. The Model T cars are going through at a rate that would cheer the heart of any agent, the record being 1,954 cars during the month of June. They are now being completed at the rate of 450 to 500 a week, with the agents, of course, clamoring as usual for more cars. Henry Ford is famed as a producer, and he is holding up his reputation in every way. He was well pleased with the victory of the Ford car in the Seattle contest, and declares that such contests do more to prove the reliability and strength of a motor car than any other kind of a contest. The foreign business is on the increase, and James Couzens, the secretary and treasurer, will leave for Europe the latter part of this month to care for matters over there.

At the Brush runabout plant, Frank Briscoe, the president, stated that the business had so far outgrown the factory that a new plant would be put up, the dimensions of which will be 871x 150, which, he says, will be the biggest single factory in the automobile trade. The present plant has been working 21 hours a day for months, both in the place on Woodward avenue and at the addition on the Grand Trunk Railroad. They will make about 2,000 of the little Brush runabouts this year, and plan to double next year. There will be very few changes on the car for 1910, the present model having proven satisfactory in every way. In connection with the Briscoe Manufacturing Company, which makes radiators, Mr. Briscoe told me that he bought half a million pounds of copper when the price was only a little above 12 cents, which puts him in a fine position for low manufacturing cost in the future. The Brush plant has ordered $80,000 worth of new machinery.

F. W. Haines, the manager of the Regal Motor Car Company, is planning a new addition to the Detroit plant which will be 217 x 54, four stories, ready for occupancy by September 1. The car has been eminently satisfactory this year, and will have only a general refinement for 1910. The body will be changed somewhat, and the wheelbase lengthened. The car has a sliding gear transmission on the rear axle, and selling at $1,250, with a 30-horsepower motor and magneto, is considered excellent value. They are now turning out 18 engines a day, and have been working day and night since last November.

Another concern in Detroit which is making rapid headway is the Grabowsky Power Wagon Company, of which Max Grabowsky is president, and John Baker, secretary. The company has doubled its capital so that it is now $300,000, and is negotiating for a new factory site, although the present place on Champlain Street will be retained. It builds trucks of 30-35 horsepower, and also three-ton trucks of 40-45 horsepower. The detachable power plant has proven to be a happy thought, permitting a concern, by having an extra power plant, to keep all their trucks in operation. The Regal Motor Car Company recently bought a Grabowsky truck for use around its factory.

At the Hupp Motor Car Company, plans and preparations are under way for a record production next year to supply additional territory. During the past year the little Hupmobile runabout has been unusually successful in Detroit and other cities, but a comparatively limited production has prevented its appearing as strongly in the East as it will next year. The runabout sells at $850 with Bosch magneto.

The city of Pontiac, which is about 26 miles from Detroit, is fast becoming an important motor car center, having four prominent factories. The Rapid Motor Vehicle Company there has made gigantic strides during the past year or two. Morris Grabowsky, the secretary, showed me plans for a new addition, 670 x 60, and another one, 300 x 60. The company will install $100,000 worth of machinery during the next four months. It is making 30-horsepower, two-cylinder trucks of 1 ton and 1 1-2 tons, with 40 to 60-horsepower, four-cylinder motors in trucks of three and five tons. They had 25 trucks in the Detroit parade. H. G. Hamilton, the president of the company, said they now have 22 acres of ground for factory purposes. The Rapid people are now the acknowledged leaders in the commercial vehicle line. Incidently, Mr. Hamilton has also been elected treasurer, and has acquired an interest in the Cartercar Company.

The Welch Motor Car Company is now interested with the General Motors Company, although the same management continues. A. R. Welch and Mr. Pack are planning to continue their big Welch cars next year, but in addition will organize the Welch Company of Detroit, that will turn out a four-cylinder car selling at $3,200. The new company will occupy the plant in Detroit formerly used by the Oldsmobile Company. The Welch cars that have very properly grown famous for their speed and durability, will, for 1910, be a four-cylinder car of 50 horsepower; a six-cylinder car of 75 horsepower, and a large four-cylinder car of 70 horsepower.

The Oakland Motor Car Company is another plant that is included in the General Motors Company, but J. W. Murphy continues to be the guiding spirit. The company has had an unusually successful year, both in competitions, proving the worth of the car, and in general sales. Plans are under way for a production of 3,000 cars for next year, the line including a 40-horsepower machine, fully equipped, at $1,700, and a two-cylinder car. There will be few changes in general construction for next year. The company has over 200,000 square feet of floor space, and is well equipped for a big production. The factory was well pleased with the victory of the Oakland in the Cincinnati hill climb, when it captured the free-for-all and two other prizes.

The Cartercar Company is now settled in its new plant at Pontiac, taking over the factory formerly occupied by the Pontiac Buggy Company. R. A. Palmer, the secretary, with his associates, have laid out an ideal factory for accurate and rapid production. The friction drive fills a unique position in motordom, being in demand by a large number of people owing to its simplicity and ease of operation. So successful has it been during the past few years that there are few things to change for the 1910 product. There will be seven models for next year, although only three different types of chassis. The two-cylinder opposed motor will be continued in the taxicab and in a roadster, as well as in a delivery wagon and coupe. The company will also build a four-cylinder touring car of 30-35 horsepower, listing at $1,600, and a very racy looking runabout at $1,000. There will be a big advance in the production next year that should make the Cartercar agents contented in mind as well as in purse.

One never goes to the Reo plant in Lansing, Mich., without expecting some great things, and there was no exception on my visit this year. I don't know of any other factory in this country that has scored any better than Reo in manufacturing motor cars, taking into consideration the money made by the company itself, and those identified with it, and by the agents, to say nothing of the satisfaction of the users. The company recently closed a deal with R. M. Owen and Company that disposed of their product for the next five years. The factory system is as near perfect as men of the ability of Mr. Olds can make it. E. F. Peer, the secretary, conducted me through the factory, which seemed an endless journey among machines and other conditions that make for a big production. It is planned to turn out 10,000 cars for 1910, a limited number being of the present two-cylinder type which continue to be in demand among agents, but most of the cars being the new four cylinders. The cylinders are 4 x 4 1-2, cast in pairs. The steering control is on the left-hand side. The car has an I-beam front axle, overhead valves, 108-inch wheelbase, selective type of transmission, high-tension magneto, and multiple disc clutch. The company owns four square blocks of ground, and is fast covering them with new buildings. Three new buildings are going up, one of them a four-story building, 65 x 125; another of three stories, 65 x 100, and a third with three floors, 100 x 200. Robert Reushaw, well-known to all those who were in the bicycle business at the time he was connected with the Pope Company, represents R. M. Owen at the factory, and looks after the agents. Mr. Olds is now on his new 97-foot cruising yacht the "Reomar," having sailed from New York on Saturday for a trip with his family through the Thousand Islands. Aside from his presidency of the Reo Company, Mr. Olds is president of the Capitol National Bank of Lansing, the Michigan Screw Company, the Atlas Drop Forge Company, and a director in a dozen or more other institutions.

At Grand Rapids, Walter Austin and his father are enlarging their plant for the manufacture of the Austin car, which has an exclusive trade and which, for that reason, has not been turned out in very large numbers. The car's brown and cream color body is well known throughout the country, and the makers cater to those folks who only wish the very best in design and construction. This year, in addition to their high-powered cars, the Austin people will make a five-passenger car at $3,000 with complete equipment. It will be known as the "Little Six" and will have a 4 3-8 x 5 1-4 motor, with a rating of 45-60 horsepower. It should be an excellent seller. The company will only make six-cylinder cars next year, the other models being a 50-75-horsepower car at $4,500, and the luxurious five or seven-passenger job with a six-cylinder motor of 60-90 horsepower, the cylinders being 5 1-2 x 5 1-2. This car is of 140-inch wheelbase, with four speeds, and all other things that might be expected in a car selling at $6,000.

As a leader in what is known as the motor buggy business, the Holsman Company, of Chicago, might naturally be expected to have great plans for next year. Mr. Hildreth told me that the factory at Thirty-sixth and Morgan Streets has been working day and night, turning out the present model, and will have the 1910 cars ready for delivery on September 1. There will be only a general refinement of the present successful cars with the prices ranging from $500 to $1,000. The product has been pretty evenly distributed, the eastern trade and the expert trade increasing during the past year. The Holsman Company has been making automobiles for eight years, and have turned out more cars of that type than any other maker.

More changes have taken place at the Mitchell Motor Car Company's plant at Racine, Wis., than at any other plant I visited during the past six weeks. All the wooden buildings have been removed, and in their place are reenforced concrete structures of the most modern kind. A new office building, 125 x 120, is now under way. It will have two floors with a garage in the basement. J. W. Gilson and J. W. Bate were at the factory last week, while President Lewis and Secretary Rogers were on the coast attending the annual agents' jubilee. Judging from my talk with Mr. Gilson, the Bate plan for economical manufacture has worked out to perfection. The cylinders on all models are the same size so they can be placed in four-cylinder or a six-cylinder car. This means a standardization of connecting rods and pistons, and should result in a great saving in costs and in the securing of parts by agents. The cylinders are cast in pairs. Three models will be made next year—a 100-inch runabout, a touring car of four cylinders, and a seven-passenger car of six cylinders. The cylinders in all cases will be 4 1-4 x 5, and a magneto will be regular equipment. The standard colors will be dark blue and maroon, with buff running gear. The lines of the new cars are radically different from this year, and every possible improvement that could be made on this year's type has been cared for. The motor with its overhead valves is a very quiet running affair and among other details are a tubular torsion bar, straight line drive, single universal joint, lower hanging of the body and floating type of rear axle on all cars. Among the new buildings put up is one of 100 x 100 now being used for a motor assembly, while in construction is a new concrete affair 250 x 250 with a saw-tooth roof; another 450 x 250 with a duplicate to follow. Certainly the Mitchell Company will be equipped to carry out its production of 6,000 cars.

The Pierce Motor Company has been reorganized and next year will produce the "Pierce Thirty" and the "Pierce Forty." The price of the car has not been settled, but the smaller one will sell for less than $1,700 with the large car at something like $2,250. It will be a conventional car so far as general construction is concerned, but will have the Pierce motor which has been so successful in marine work, there being 20,000 Pierce motor boats in use now. The president of the new Pierce Motor Company is C. L. McIntosh, who is treasurer and part owner of the J. I. Case Threshing Machine Company, one of the biggest manufacturing concerns in the West. The vice-president is Fred Robinson; secretary, John Peebles; treasurer, C. J. McIntosh, while J. G. Cowling, for ten years with the Case Company, is general manager. A. J. Pierce, who has been making automobiles since 1893, continues as general superintendent.

The Jackson Automobile Company is preparing for a big production as a result of the new additions to their factories at Jackson, Mich. Two new buildings are in the course of erection, each 240 x 60 and four stories high. An addition is being built to the motor plant, 200 x 60, three stories. Charles Lewis, G. A. Matthews, and F. L. Holmes, of the company, were responsible for the hospitable reception given the Glidden tourists by the Jackson Chamber of Commerce when they passed through that city en route for Kalamazoo. The Jackson line next year will consist of three four-cylinder models, one selling at $2,250; another at $1,700, and a 20-horsepower car at $1,250. The changes for next year will include larger wheels and tires, and a longer wheelbase, other than which the Jackson construction will be continued. Mr. Matthews told me that the Fuller Buggy Company, which he owns, will turn out a motor buggy for 1910.

Before reaching New York, I visited the plant of the Maxwell-Briscoe Motor Company at Tarrytown, which is one of its big factories and the headquarters of that concern. Benjamin Briscoe' leadership in motor affairs generally is not to be wondered at when his success with the Maxwell-Briscoe Motor Company is considered. The manufacturing is down to the finest point, and a clean cut system generally prevails in all the departments. The company now owns all the real estate at Kingsland Point, and has covered it with factory buildings. They have also bought the old factory of the Rand Power Company in Tarrytown, and only recently purchased another big factory near Providence, R. I. These are in addition to the big plant at Newcastle, Ind. By their method of distribution, which is original with Mr. Briscoe, the company is able to care for all its agents on a fair basis. The percentage system prevails, and every agent knows just how many cars per month he is going to receive. The selling organization of the Maxwell-Briscoe Company is one of the best in the country. The little $500 car has been a great success, and will be continued next year to the tune of many thousands, while great things are expected of the new Model Q, equipped with a four-cylinder, 20-horsepower motor, embodying all the well-known Maxwell features, and yet sell for $850. Some other sensational models are planned for 1910, but in all of them the John D. Maxwell ideas, such as three-point suspension, thermo-syphon cooling, and unit engine clutch, and transmission construction will prevail. The company plans to make 18,000 to 20,000 cars in its four factories next year.

Great success has attended the efforts of the Atlas Motor Car Company at Springfield, Mass., in turning out their two-cycle motors. They are making heavy inroads on the taxicab trade in New York, the two-cycle, two-cylinder motor of 20 horsepower giving unexcelled service even in the hands of hard drivers. The New York branch sold 148 of these cabs during the past four months. The company also makes a three-cylinder, 30-horsepower touring car, and a six-cylinder, 50-horsepower runabout that has exceptional speed. The policy and line for 1910 has not been settled by Harry A. Knox and W. G. Morse, but it is not expected that there will be any radical changes from the satisfactory type of this year. The new addition to the factory was completed about a month ago, giving the needed additional facilities for making the 1910 cars.

Generally speaking, I found the entire trade in exceptionally fine shape, and full of optimism on 1910 as a record year for the sale of automobiles.

PUTTING STRENGTH AND ENDURING QUALITIES INTO THE AUTO

By HENRY SOUTHER, Association of Licensed Automobile Manufacturers.

It is probable that there has never been a period of such rapid development in the metal trades as has occurred in connection with the automobile industry. The work was largely started and carried through by those pioneer automobile manufacturers constituting the Association of Licensed Automobile Manufacturers.

In America, the tremendous importance of heat treatment of steel has been grasped and the principles involved therein carried to an ultimate conclusion. Intelligent heat treatment is quite as essential as the quality of steel; a commonplace steel may be given very good physical qualities by proper heat treatment, and the best of steel can be ruined by lack of it. There must be thoroughness in the various operations of annealing, hardening and tempering. Treatment carried on with sufficient care makes uniformity of product possible.

The difference between ordinary material and the best of material is a great one. For example, the elastic limit of ordinary steel is 40,000 pounds to the square inch, with, say, a reduction of area of 50 per cent. Properly heat-treated, nickel steel will have an elastic limit of two or two and one-half times this figure, and yet have 50 per cent. area reduction or more.

Brittleness does not follow intelligent heat treatment; and the enduring quality is increased in greater ratio than the elastic limit. Consequently crystallization, fatigue or whatever the cause of breakage we are to prevent, is called, is less likely in a properly heat-treated and tempered material than in an annealed and soft specimen. This having been discovered in the laboratory and established in actual practice, is now accepted by the metallurgical world, reversing previous general belief.

Another commonly accepted belief has been that the stronger a piece of steel is the stiffer it is; for example, that if one metal is twice as strong as another, it will bend only half as much under a given weight. But actual tests have shown that a chrome nickel steel, having an elastic limit of 150,000 or more pounds per square inch, bends under a given load the same amount as a carbon steel. This is true as long as the load is within the elastic limit of the weaker material.

The elastic limit of a well-tempered piece of spring steel is above 150,000 pounds per square inch. If a spring be made of soft steel and not loaded beyond its elastic limit, it would return every time to its original shape, but the deflection would not be sufficient to make a good spring; it would be hardly noticeable. The automobile industry has forced the spring maker to depart from his old materials and methods.

Assume that a good .20 carbon steel has been used with satisfaction for a year or two on a given design of crankshaft, neither bending nor breaking through long-continued use. Assume the bearing surfaces are as small in area as possible to run properly. A crankshaft of highly treated chrome nickel steel, having an elastic limit four or five times as high as the .20 carbon material would be no stiffer, but would have increased life and last much longer.

Really sound knowledge as to steel has been spreading fast among the intelligent manufacturers, who use much discrimination in separating the false from the good. They have established testing laboratories and examine for themselves what materials they buy. There are, perhaps, a dozen first-class grades of steel in the market (and America has a market at least as good as any in the world, with, of course, always the option of buying abroad for any real or fancied reason) suitable for the highest class of automobile construction.

Bronze is still an important factor. Here the casting method is all important.

Aluminum alloys are of great interest.

Where any form of plain journal is used the bearing metal question seems to have settled down, to a high grade tin-antimony alloy, running against a soft shaft; a hardened shaft running on a good phosphor-bronze; or a soft shaft running on a white bronze. All of these combinations are giving good results.

The larger part of the expense of an automobile engine cylinder is in the finishing labor, and not in the iron. In the foundries there are many complex conditions arising from what a layman would think trifling matters, in the production of first-class, sound cylinders.

QUAKER CITY APPOINTS ITS SHOW COMMITTEE

Philadelphia, July 19—The initial steps were taken last week by President J. A. Wister, of the Philadelphia Automobile Trade Association, in preparing for next winter's show. He appointed W. J. Foss, of the Pierce-Arrow agency, and James L. Gibney, who represents Continental and Gibney tires in the Quaker City, a committee to run the exhibition, which will be held between the New York and Chicago shows, if that week can be secured—possibly from Wednesday to Wednesday, as was the case last year. Secretary J. H. Beck, without whom a Philadelphia show could hardly be a success, will, as before, look after the details and manage the show proper. At this writing, it seems as if the promoters would again be compelled to labor under the handicap of a hall about 50 per cent short of the space requirements, the local armories being about the only available buildings in sight.

G. W. Butler and Winton That Won 1909 Upkeep Contest

WINNERS ANNOUNCED IN WINTON CONTEST

The $1,000 first prize in the annual Winton upkeep contest was won by G. W. Butler, who drove his car 17,003 miles without spending a single cent for repairs. Butler's record is all the more remarkable because his car was also a prize winner in last year's contest, when it had a score of 5,155 miles without repairs, and also because the car carries a limousine body. During the contest, the competing chauffeurs were required to file monthly reports, attested by their employers, and at the end of the contest both chauffeurs and employers were asked for sworn affidavits. The list of prize winners follows:

First prize, $1,000—G. W. Butler, chauffeur for J. E. Clenny, Chicago; 17,003 miles, no expense.
Second prize, $500—J. J. Boyce, chauffeur for Isaac Bacharach, Atlantic City, N. J.: 11,000 miles, expense 30 cents.
Third prize, $250—W. L. Losee, chauffeur for G. W. Frost, Verona, N. J.; 10,595 miles, no expense.
Fourth prize, $150—J. W. Tracy, chauffeur for T. N. Barnsdale, Pittsburg: 15,669 miles, expense $31.15.

Six other prizes of $100 each were awarded to Arthur Donovan, New York; L. Avenmarg, Cleveland; William Richards, New York; John Wilson, Cleveland; Miles Fellers, Cleveland, and Harry Rosander, Chicago.

The total mileage of the prize winners was 118,503 miles, and their total repair expense $127.30, which makes the average expense per car per 1,000 miles $1.07.

MAXWELL-BRISCOE AGENTS' CONVENTION

Newcastle, Ind., July 19—The 1909 convention of the district supervisors and managers of the Maxwell-Briscoe Motor Company went into session at this city last week. Most of the delegates arrived from Detroit, where they had witnessed the start of the Glidden tour, on a special train, accompanied by the Maxwell band. The first day's session included the discussion of the selling policy of the company and other matters of interest to the closer family circle of the Maxwell organization. Afterward the Maxwell men were the guests of the city, which had prepared an elaborate entertainment at the Country Club. Fireworks, a band concert and a general jollification at Maxwell Park were attended by some five thousand people.

Among the delegates were Benjamin Briscoe, J. D. Maxwell, F. D. Dorman, A. B. Barkman, A. R. Gormully, Ernest Coler and J. D. Moore, of the company's home office; Col. K. C. Pardee, New York City; J. M. Austin, Atlanta, Ga.; C. E. Munroe, Buffalo; A. I. McLeod and Bob Davis, Detroit; F. J. Linz, San Francisco; Thos. Dunn, Pittsburgh; F. J. Tyler, Boston; C. G. Bleasdale, Cleveland; B. E. Stimson, Minneapolis, Minn.; J. I. Handley and R. I. Creek, Chicago; W. S. Hathaway, Kansas City, Mo.; Gabriel Chier, Detroit; T. E. Lester, Dallas, Tex.; H. E. Rooklidge, Kansas City, Mo.; F. R. Tate, St. Louis; E. E. Cohen, Portland, Ore.; M. A. Stacksteder, Dallas, Tex.; C. J. Simons, St. Louis.

SOUTHERN SHOW WILL HAVE OVERFLOW

Atlanta, Ga., July 20—They are going to exhibit automobiles out in the street at the big show here in November. General Manager S. A. Miles, of the National Association of Automobile Manufacturers, has been here looking over the ground, and making a scouting trip through and about the Atlanta Auditorium-Armory in search of more space. He expects nearly 100 exhibitors at the coming show, and has space for hardly more than two-thirds of that number. To meet the requirements of the show management Atlanta will turn over one whole block of Courtland street, adjoining the Auditorium, and this space will be roofed over with canvas and a number of exhibits will be placed in the enclosure. In this manner it is possible that most if not all of the intending exhibitors can be accommodated. The people here intend to have a real show at any cost.

CONVENTION OF AJAX-GRIEB MANAGERS

The branch managers and agents of the Ajax-Grieb Rubber Company will meet at the factory at Trenton, N. J., July 28-31. The representatives from Seattle and San Francisco are already on the way. Together with the more pressing business of the convention those attending will be present at the Brighton Beach 24-hour race.

Dallas, Texas.—The White Steamer Automobile Company has made plans for the erection of a two-story and basement fireproof garage building. It will cost $50,000, and will be equipped with steam heat, electric light and power and electric elevators.

New Testing Track of the Maxwell-Briscoe Motor Company, Just Completed for the Newcastle, Indiana, Plant

E-M-F BUYS DE LUXE PLANT—WILL BUILD SMALL CAR

DETROIT, July 19—Million-dollar deals are coming so close together in the local automobile field that they no longer excite more than passing comment, although the changes effected thereby are of widespread importance. Following close on the acquisition by the General Motors Company of the Cadillac Motor Car Company, the price paid being approximately $4,500,000, comes the announcement that the E-M-F Company has purchased the plant and business of the De Luxe Motor Car Company at Clark and River streets, Detroit. The price paid is not made public, but is in the neighborhood of $800,000, the plant carrying that amount of insurance and representing a far heavier investment in the way of buildings and machinery. All the land, buildings and machinery are included in the buy as also are patents, drawings, tools and fixtures for making the Car De Luxe, to the manufacture of which the plant has hitherto been exclusively devoted.

The land comprises something over fifteen acres, about half of which is at present covered with modern factory buildings admirably suited to the purpose for which it will be used. Beside the property of the De Luxe Motor Company the E-M-F Company also purchased about four acres additional. This latter lies between the Wabash Railroad tracks and Fort street and adjoins the plant of the Timken Axle Company.

Several other parties had been dickering for the De Luxe plant, which is a valuable one, but Walter E. Flanders, president and general manager of the E-M-F Company, shattered all previous speed records by opening negotiations in the morning and turning over the cash in the afternoon, closing the deal before others knew what was transpiring.

Coincident with this transfer comes the news that the E-M-F Company will next season put on the market a new car to be known as the Studebaker-Flanders "20," and which will sell for less than $750, the exact price yet to be determined. The Studebaker-Flanders "20," which will be marketed by the Studebaker Company, now handling the entire E-M-F output, will be a four-cylinder car, 3 5-8-inch bore by 3 3-4-inch stroke, with a 100-inch wheelbase. It will have a sliding gear rear axle transmission, 32-inch wheels, pressed steel frame and the regular equipment will include magneto. It will be made in two styles, a two-passenger runabout and a four-passenger suburban. Twenty-five thousand of these cars will be made during the twelve months beginning January 1 next, according to Mr. Flanders, and to show that the concern means business 150 workmen were rushed from the E-M-F plant over to the new acquisition almost before the ink was dry on the papers closing the deal.

Meanwhile the E-M-F Company is more than doubling the size of its present plant on Piquette avenue, the structures now utilized being increased in height to four stories, an addition 70 x 480 feet, and four stories in height being built to connect the present buildings. The manufacture of De Luxe cars will, it is announced, be continued on a limited scale in the plant just taken over by the E-M-F Company, but the greater part of the plant will be devoted to the new "Twenty."

SEVERAL BIG DEALS ON IN INDIANAPOLIS, TOO

INDIANAPOLIS, IND., July 19—David M. Parry, for almost thirty years one of the leading carriage manufacturers of the country, has decided to enter the automobile manufacturing field. He has announced plans for a factory to be located in this city to cost about $100,000, while the company will be capitalized at about $1,000,000. As a preliminary to entering the auto making business, Mr. Parry resigned as president of the Parry Manufacturing Company a few weeks ago, although he still retains his interests there. The new concern will be known as the Parry Motor Car Company.

Two models, to be known as the Parry, will be manufactured. They will consist of two cylinder and four cylinder models, selling at $1,250 and $1,400, respectively. It is Mr. Parry's aim to make his plant the largest of its kind in this city.

The first cars will be ready for the market in September. Machinery is being ordered and plans are under way for the factory buildings, the erection of which will start almost immediately and will be pushed vigorously.

Popular-Priced Cars by Cole Motor Car Company

Another company recently formed in this city is the Cole Motor Car Company, which will manufacture two popular priced types of cars. J. J. Cole, the well-known and successful carriage builder, is president of the new company.

The Cole "30" and "20" four-cylinder cars are the result of two years' careful study and experimentation with different types of cars, the present model having been subjected for several months to the most severe road tests that could be devised.

That the car as it now stands is a success is partly due to the fact that Mr. Cole has been able to associate with his company one of the leading mechanical superintendents of the country, who for fifteen years has been connected with leading automobile manufacturers.

The output of the Cole Motor Car Company will be marketed by the Henderson Motor Sales Company, of which Charles P. Henderson, formerly of the Henderson-Hull Company, Savannah, Ga., is vice-president and manager. Mr. Henderson, who is closing his first season in the automobile business, has been connected with the carriage trade for many years.

With him actively will be H. C. Lathrop, formerly manager Indiana branch of the A. D. Baker Company, who is secretary and treasurer of the company. Also, as stockholders, Leonard Carter, Jesup, Ga., Dr. A. B. Lathrop, Swanton, Ohio, and J. J. Cole, Indianapolis, Ind.

DETROIT'S ENVIABLE POSITION IN THE INDUSTRY

DETROIT, July 19—Gliddenites and other visitors during the days preceding the start of the A.A.A. contest were given a new insight into the importance of this city as the center of the automobile industry, being given entree to all the local plants and provided with easy means of reaching any or all of them. Nevertheless, even those who looked over the field cannot fail to be still further impressed with the magnitude of the industry as shown in the figures just compiled by an expert statistician connected with the Detroit Board of Commerce.

These show that Detroit possesses fourteen factories devoted exclusively to the manufacture of automobiles, this statement not taking into account the scores of institutions engaged in making motor car sundries and accessories, chief of which is the immense tire plant of Morgan & Wright. These fourteen factories at the time the canvass was made employed 14,670 men, with an annual payroll of $9,882,000. The companies are capitalized for $6,250,000. The value of the output this season will be $54,325,000, of which $2,000,000 is represented in exports.

Elmer Lovejoy, with His Franklin, Makes Good in a Wild Goose Chase

A Wild-Goose Chase—The first automobile ever used in the State of Wyoming, and, it is believed, anywhere west of the Mississippi River, was built by Elmer Lovejoy, of Laramie. He is now president of the Laramie Automobile Club, and in his hours of recreation is a hunter as well as an autoist. Not long ago he set out upon what was literally a wild-goose chase; but he bagged the geese and bore them back home as a proof that this cbase, proverbially vain, was not futile and fruitless if undertaken with an automobile. He made a forty-mile run from Laramie through a rough country in an hour and a quarter, and came upon the geese in flight. By running bis car under them as they were rising from their feeding grounds he was enabled to bring down seven. Mr. Lovejoy looks back with considerable pride on the old car with which he, in the early days of automobiling, opened the eyes of the people of Wyoming. His present car, however, is a Franklin of the latest design, which is handled in Laramie by a company of which he is a stockholder.

Firestone Truck Carried Signs, not Tires—Published reports that the truck whose accident near Valparaiso, Ind., held up the Glidden Tour nearly an hour was loaded with Firestone tires is hotly denied by H. S. Firestone, who says: "This particular truck was carrying a load of Firestone signs, not tires, from Detroit to Chicago, and had nothing to do with the Glidden Tour. Contesting cars using Firestone tires have never yet felt the need of being accompanied by loads of fresh tires, as Firestone tires are not made that way. For instance, in the New York to Seattle race two of the cars started and finished without carrying any extra tire equipment whatever, and I rather think that this 4,000-mile race was a somewhat stiffer proposition on tires than the Glidden Tour has ever been. We are interested in the Glidden contest only as a car test, and not from a tire standpoint, as the management ruled against making a record of competitive tire service."

Some Mile-a-Minute Baseball—The bewhiskered Harlem goats who browse on the rocks and tomato cans in the vicinity of 142d street and Lenox avenue were startled from their dinners last Saturday by a fierce bombardment of three-baggers and home runs. The shrieking of fans—both radiator and flywheel types—filled the air with a weird music, and the voice of the umpire was heard calling "Strike tuh!" The Harlem goats are accustomed to baseball of the usual variety, but tbe brand dished out by the members of the New York Automobile Trade Baseball Association filled them with awe and trepidation. However, it was only the Thomas Company walloping the Studebaker Company to the tune of 16 to 3. During this slaughter the Republic Rubber Company was battling with the Pierce-Arrowites, whom they finally downed, 8 to 6. Sunday afternoon the Diamond Rubber Company scored a 15 to 1 victory over the Packard team.

The Horsefly Takes Revenge—F. M. Hoblitt, of the American Locomotive Company, is responsible for this marvelous tale. "I have seen one coyote stampede 2,000 steers, a mouse an elephant and a bumblebee a gang of harvest hands," says Mr. Hoblitt, "but I never saw a horsefly stop an automobile till yesterday. On the road between Cleveland and Columbus our car suddenly came to a dead stop. All mechanical minds instantly set to work, and it was soon found that the engine was getting no gas. Further investigation showed that in some way a large horsefly had been drawn into the auxiliary air inlet in such a way as to shut off the air and choke the engine to a standstill."

Atlantic City's Auto Patrol—Manager "Billy" Taylor, of the Philadelphia branch of the Olds Motor Works, announces the early completion of a patrol wagon which is being built wholly at the branch house for the Atlantic City police department. It will have a 132 1-2-inch wheel-base with a special frame, upon which will be mounted a 4-cylinder, 40-horsepower engine. Manager Taylor has just closed with James S. Boyd to represent the Oldsmobile in Norristown and Montgomery county, Pa., during 1910. The latter is just about finishing the big new Keystone garage, which has been in course of erection for six weeks, and which the contractors have just turned over.

Novel Factory for Hupmobile—The Hupp Motor Car Company is just finishing the removal of its equipment and the installation of new machinery in its new factory at Jefferson avenue and Concord street, Detroit. The building is in the shape of a capital U, each of the wings being 350 x 50 feet and the connecting portion 131 x 60 feet. It is one story high, except the part facing Jefferson avenue, where the offices will be located, so that it will not be necessary to pass any of the work from floor to floor. The capacity of the enlarged factory is conservatively designed to be at least 25 cars a day.

Diamond Tires Distinguished—Diamond tires played a leading part in two recent events of a widely dissimilar character. On July 10 Hanshue on an Apperson and Dingley on a Chalmers-Detroit won the two road races at Santa Monica, Cal., both using Diamonds. On July 12, at the start of the Glidden tour, Diamond tires were observed on the rims of fourteen of the forty-one starters. One of the contestants on the list was the McIntyre buggyabout, which used a special type of solid tires recently brought out by the Diamond company.

Gary Company Incorporates.—The Gary Motor Company has just been incorporated in Muskegon, Mich., for the manufacture of automobiles, and, later, of motor trucks. The incorporators are Alfred C. Gary, nephew of Judge Gary, of the steel trust; William L. Simonton and James L. Maloney, of Chicago. Work will be commenced within a week on a factory building and it is expected to have the plant in operation October 1.

Keystone Grease Lubricated Maxwell Non-Stop—On the recent run of the Maxwell car which recently covered 10,000 miles of road travel without stopping the motor, Keystone grease, the product of tbe Keystone Lubricating Company, of Philadelphia, was used exclusively. The test covered a period of three weeks, and is a world's record for non-stop runs.

Record of Locomobile Patrol—The city authorities of Baltimore have had a Locomobile patrol wagon in service since May 19, and are much satisfied with its performance. The car, in addition to patrol work, responds to all fire and ambulance calls in the central district. It has covered about 2,500 miles and has never been out of commission.

New Weston-Mott Factory—The Weston-Mott Company of Flint, Mich., manufacturer of automobile wheels, has nearly completed an addition to its factory, 300 x 165 feet, and is already planning a second addition, 500 x 75 feet, two stories high. The company expects to have 1,600 men on its payroll by October 1.

Another Puncture-Proof—The Cleveland Puncture-Proof Tire Company, of Cleveland, was incorporated last week with a capital of $20,000. The company controls the patents on a tire which, it is claimed, has been found puncture-proof in tests lasting over two years, and will probably erect a factory in Cleveland.

New Departure Company Busy—The New Departure Mfg. Co., manufacturer of "Two-in-One" ball bearings, is working its factory at Bristol, Conn., 22 hours daily on day and night shifts to keep up with its orders. Large contracts are reported for bearings to be used in 1910 models.

IN AND ABOUT THE AGENCIES

Benz, Atlanta, Ga.—The Benz Import Company of America has placed the agency for the State of Georgia with the Georgia Motor Car Company, 68-70 Edgewood avenue, Atlanta. G. W. Hanson, well known in Southern auto circles, will give his personal attention to marketing the car.

White, Baltimore—The White Automobile Company has been organized in this city and has bought out the White Garage Company, at Park avenue and Biddle street. The new company will continue as representative of the White steamer, and is planning a modern two-story garage.

Hudson, Scranton, Pa.—The Lackawanna Automobile Company, 245 Wyoming avenue, already agent for the Matheson and Chalmers-Detroit, has taken the agency for the Hudson roadster.

PERSONAL TRADE MENTION

C. J. Corkhill, for the past eight years Western sales manager for the Olds Motor Works, recently resigned that position and joined the Apperson Bros. Automobile Company. He will have charge of the sales of the Apperson "Jack Rabbit" in the territory west of the Mississippi River, making his headquarters at Omaha, Neb.

L. P. Halladay, formerly general manager of the Streator Motor Car Company, Streator, Ill., has been appointed manager of the automobile department of the Staver Carriage Company of Chicago.

A. A. Jones, long identified with the Philadelphia branch of the Ford Motor Company, has succeeded to the local sales managership of the Maxwell branch in the same city.

C. E. Davis, superintendent of the American Locomotive Company's plant at Providence, R. I., has resigned his position and gone West.

DEATH CLAIMS A PIONEER

George T. Robie, president and founder of the Excelsior Supply Company, and one of the leading business men of Chicago, died at the Chicago Hospital early Sunday morning. Mr. Robie became ill late in the week and late Saturday night it was found that an operation for appendicitis would be necessary. He was immediately removed from the Hotel Windermere to the hospital, where the operation was performed. Owing to the advanced stage of the trouble, Mr. Robie was unable to survive and passed away early Sunday morning. Mr. Robie was born in Walworth, N. Y., March 26, 1853, and came to Chicago at the age of 20. In 1876 he established the Excelsior Supply Company and soon became a leading dealer in sewing machine supplies and equipment. When the bicycle became prominent Mr. Robie took on bicycle supplies and in a short time became the leader in that line. Following his policy of aggressiveness, as soon as the automobile became an established element, the Excelsior Company assumed the same position in the motor car supply business that it had previously held in the line of sewing machine and bicycle supplies. Mr. Robie held a prominent position in the National Association of Manufacturers and in the Chicago Association of Commerce. He was one of those who made the recent trip to Seattle. He was a member of the Union League, Chicago Athletic, South Shore and Chicago Automobile Clubs. Mr. Robie also was prominent in Masonic circles. He leaves a widow and one son, Fred C. Robie, who has for some time past been the working head of the Excelsior Supply Company. Funeral services were held on Tuesday at Englewood Masonic Temple.

TAXICABS AND TRANSIT

Bagdad, Turkey—A company has been formed to run a line of buses from Khanikin, on the Persian frontier, via Bagdad to Kerbela, the sacred city of the Shiite sect of Mohammedans. There are no roads, but the country is perfectly level and smooth and fairly high speed may be maintained.

New Orleans, La.—The Taxicab Company of New Orleans, Ltd., has been incorporated with a capital stock of $125,000. The officers are E. R. Thomas, president; Pierre Crabites, vice-president and treasurer, and L. M. Vitoli, secretary.

Boston, Mass.—The Taxa-cab Company, of Boston, has been incorporated to do a general cab and truck business, with a capital stock of $250,000. The president is R. F. Guild and the treasurer and clerk F. H. Mesmithe, 53 State street.

Cleveland, O.—Two auto buses owned by Conger and Langdon have been put in service in the Cleveland park system between Euclid Avenue and Gordon Park, along the East Boulevard. The fare for the twenty-minute ride is 10 cents.

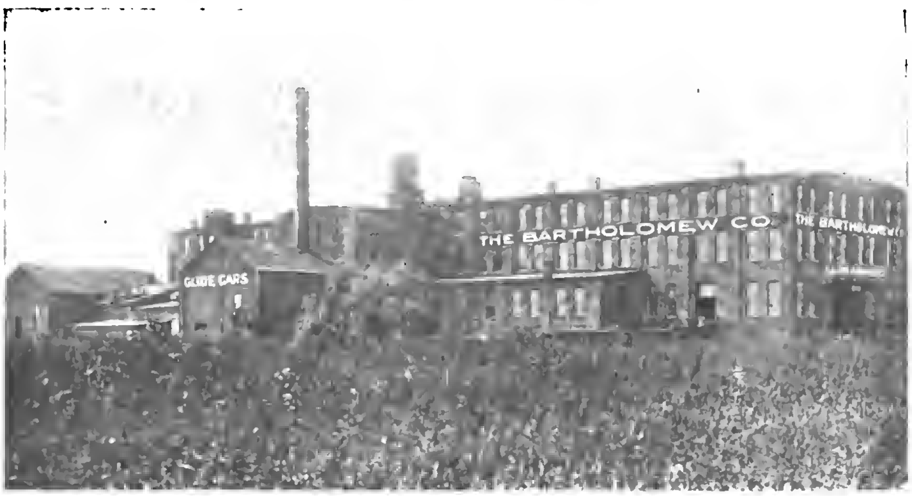
Memphis, Tenn.—Local men have incorporated the Corbitt Taxicab Company with $180,000 capital stock. S. R. Corbitt is president, J. J. Freeman, secretary, W. H. Kyle, treasurer, and Ben Peebles, general manager.

RECENT PUBLICATIONS

Packard Motor Car Company, Detroit—In thorough keeping with the quality and reputation of its product is the appearance and matter of the catalogue of 1910 Packard cars. In all ways one of the masterpieces of automobile factory publications, the new edition is an advance over the make-up of the general booklets descriptive of the automobile trade. E. Ralph Estep is responsible for the new one, as he has been in the past of the Packard publicity and advertising, and as usual he has succeeded in publishing one of the neatest, most conservative and pleasing editions of the year. The binding is in heavy gray card, and the stock is of exceptionally heavy carded paper, with the typography and illustrations in harmony. There is no color used, as has been prominent heretofore, the entire appearance being of white and gray, the latter accentuated by a grayish border. Packard Thirty and Packard Eighteen are illustrated in many full and part-page cuts, in all body styles—touring cars, roadsters, close-coupled, landaulets, limousines and a newcomer called the phaeton. Different tops give another series, intermingled with the straight and familiar types. Birds'-eye views show the seating capacities and arrangements of the various bodies, while three-quarter approaches indicate the methods of control, the fender systems, and many other points of interest to the prospective customer. The **Packard truck,** an important member of the family, is also given detailed attention of the same quality as that bestowed so liberally upon the pleasure vehicles. Chassis construction is taken up at length, with line cuts of the completed cars and of the various assemblies, accompanied by accurate notes. The reader is not bothered by the matter of prices, the most evident part of some makers' catalogues, and is apt to be accordingly more interested. Tables near the rear cover contain the selling price of all models, with the different body or top extras, and the specifications.

Westinghouse Electric Motors—The Westinghouse Electric & Manufacturing Company, Pittsburg, Pa., has issued a handsomely printed little booklet describing the application of its line of small motors to varied uses in office, store and shop. From it many useful suggestions may be obtained. All sorts of small machines can be economically driven by these motors, especially buffing machines, small drills, hack saws and blowers.

New Chicago Agency of the Renault



St. Louis Company's Factory, Now Occupied by Bartholomew

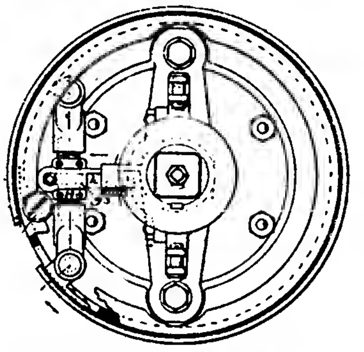
The Bartholomew Company, maker of the Glide cars, has just purchased the factory of the St. Louis Motor Car Company at Peoria, Ill., which it will operate together with its present plant. This acquisition will double the company's capacity and will enable it to take care of an increased output in 1910.

SOME SELECTED AUTOMOBILE PATENTS

Issue of June 29

926,141. Clutch—Charles Schmidt, Cleveland, O. Filed Jan. 15, 1906.

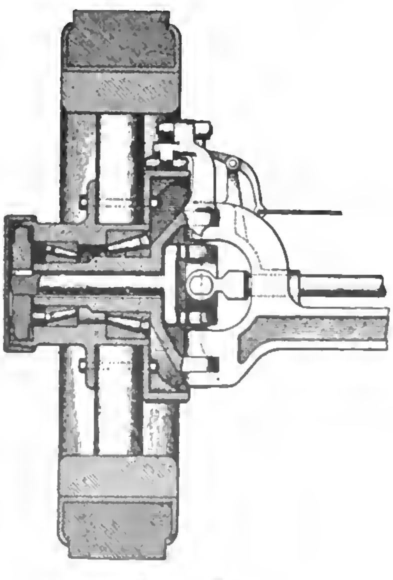
This would appear to be the clutch used on the Peerless cars with slight structural modifications, in the means of supporting the clutch members on the shaft. The clutch is of the internal expanding type, the band being expanded by means of right- and left-screw working in corresponding nuts in the ends of the band and actuated by a lever under the action of a collar and spring. The collar is provided with suitable forks for connecting with a stirrup upon the shaft carrying the operating pedal whereby the said collar may be withdrawn or released and the clutch contracted or expanded at will.



Peerless Clutch Modification.

926,313. Traction Wheel—Chester T. Bangs, Chicago, Ill. Filed Dec. 10, 1906.

A combination steering and driving wheel for heavy vehicles with braking means which will operate in any position that the wheel may assume with regard to the axis of the vehicle is the subject of the above patent. The drive is communicated from a lateral shaft to a central spindle within the wheel hub by means of a universal joint. The wheel is clutch-driven as in ordinary practice. A supporting shell is fitted with a pair of radial arms which pivot in a yoke attached to the axle. The brake apparatus is suspended from an extension of the supporting shell and actuated by a bent lever on the yoke. The wheel revolves on bearings on the shell, the brake drum being bolted to the spokes and serving as part of the nave box.



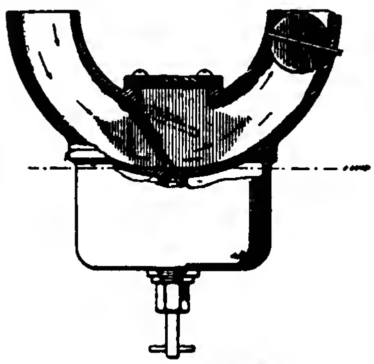
Bangs' Heavy Traction Wheel.

926,330. Electric Ignition Device—Theodore Hubert, New York, N. Y. Filed April 4, 1906.

This refers to the Splitdorf magneto which is of the low tension type, the current being transformed in a separate coil. The means of altering the time of sparking by rocking a collar on the armature axis consists of a pin upon the internal surface of the collar acting in a spiral groove in the axis so that the axial motion of a handle attached to the collar gives the desired advance or retardation of the time. Connections whereby a dual system of ignition can be used without interference with each other and employing the same distributer for both systems are also features of the specification.

926,533. Carbureter—Alexander Winton and Harold B. Anderson, Cleveland, O. Filed March 9, 1907.

This refers to a carbureter combining a float chamber and means for regulating the level of the fuel therein, the chamber being integral with a casting comprising a curved air inlet and mixture passage in which is fitted a check-valve. This valve rises with the suction of the motor and in so doing uncovers the opening from the float chamber to the mixture passage, closing the same when suction ceases. The lower portion of the said passage is fashioned to contain a body of fluid therein so that volatilization is rendered easy and sure.



Winton Carbureter Arrangement

926,540. Engine—Hendrik E. B. Blomgren, Palmyra, N. J. Filed Jan. 27, 1906.

This is an inverted internal combustion motor of the four-cylinder two crank type. Each pair of pistons is attached to a weighted plate provided with bearings which permit it to slide up and down on circular shafts fitted in a frame constructed for the purpose. A connecting-rod serves to connect this plate with the corresponding crank and works within a channel between the two cylinders of the pair. The valves are arranged in the head of the cylinders. The construction of the engine is designed to enable any part to be replaced in case of accident and to allow accessibility of all parts.

926,157. Turbine Engine—Carl W. Weiss, New York, N. Y. Filed Sept. 19, 1903.

Weiss here shows an internal combustion turbine, consisting of a rotating drum provided with peripheral curved blades revolving in a casing, and two nozzles in communication with the interior of this casing, the one delivering a continuous stream of products of combustion and the other to deliver simultaneously a stream of steam. No cooling means is provided for the products of combustion before impinging on the curved blades, but the inventor relies on the lower temperature of the steam to reduce the temperature within the casing. The first nozzle is fed from a receiver and exhaust ports are arranged at various points on the circumference of the casing.

926,134. Compound Internal Combustion Engine—Sidney A. Reeve, Worcester, Mass. Filed June 30, 1905.

Reeve here utilizes the exhaust from the high-pressure cylinder to operate a low-pressure cylinder with automatic governors and devices for regulating the inlets of both cylinders according to the load thereon. This engine was recently fully described in these columns.

Issue of July 6, 1909

926,769. Spring-Wheel—James E. Reilley, Newark, N. J. Filed Nov. 2, 1907.

In this, Reilley interposes between the felloe and the tire a series of blocks, over which springs are wound. These connect every fourth pair of external blocks, and every pair of internal. Since the wire springs are the only parts which prevent the rotation of the rim relative to the felloe, an unusual strain is placed upon them. That is, the springs must act as springs and carry the driving strain, as well.

926,771. Ball-Bearing—Ernst Sachs, Schweinfurt, Germany. Filed Apr. 17, 1907.

A form of ball retainer used on the well-known Fichtel and Sachs ball bearings, or more correctly a means of assembling and dissembling the same. The internal race is made with a deep central groove, into which an oblique groove leads. Through the medium of the diagonal groove the race is really screwed into place.

926,797. Transmission-Gearing for Automobiles—Martin L. Williams, South Bend, Ind. Filed Feb. 12, 1906.

This is a plan to combine the engine, transmission, clutch and other parts of the power plant into a single unit. In doing this, the engine is set across the frame, and back of it in a parallel line is the transmission shafts two in number. Since there are three separate drives from the engine to the transmission shaft and two or three differentials, it seems fair to say that this is a complicated device.

926,848. Carbureter—John A. Carlson, Denver, Colo. Filed Mar. 27, 1908.

For simplicity, Carlson's carbureter takes the cake, since it comprises but an angle-shaped pipe, with an air inlet at the bottom, governed by a spring, which is inter-connected with the fuel inlet in the side of the pipe. As the speed of the engine draws in more air, the opening of the air valve also opens the fuel passage, so more fuel enters.

926,892. Explosion-Engine—John Peterson and Frederick O. Peterson, Detroit, Mich. Filed Feb. 24, 1908.

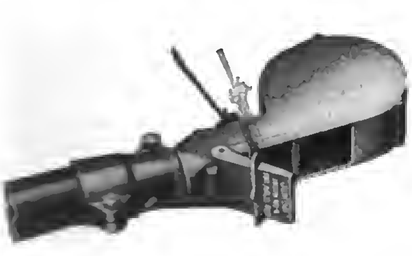
A two-cycle engine with fuel injection. This is arranged so that the carbureter is mounted high up on the side of the engine where it has communication with the crank case. The latter has the usual air inlet, and after compressing the air, it is blown through the carbureter, which is little more than a float chamber with a fuel-regulating device. In action, then, the suction stroke does not really draw in anything, for the feed is by pressure, the mixed air and gasoline vapor being forced in. This should result in a very complete charge, although it would doubtless be rather wasteful of the fuel.

926,919. Gearing—Alfred N. Adams, Omaha, Neb. Filed Dec. 28, 1908.

This is a four-wheel drive and steer arrangement, in which the usual transmission is replaced by no less than four small transmissions, one on each stub axle. From the drawing it would appear as if the plan was to locate the engine in the center of the frame.

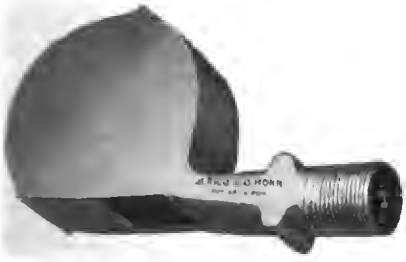
Information for Auto Users

"Jericho" the Horn—In response to the demand for an inexpensive exhaust horn, the Randall-Faichney Company of Boston has brought out a horn designed to be attached to the exhaust pipe at the rear of the muffler, thus doing away with the complication and expense of the usual cut-out. The device fits on the extreme rear end of the exhaust pipe, so that no cutting of the



JERICHO HORN SHOWN OPEN

pipe is required; the connection is made by means of a clamp coupling which is furnished in sizes to fit any pipe. The construction of the horn itself is novel. It contains no reeds to choke or become clogged, and as the opening is on the under side, obstructions will fall out of themselves, instead of being trapped and retained. The construction and method of attachment will be obvious at once from the cut. Its tone is quite unique. At low speed, for town use, it is said to resemble the call of a loon; but for country driving it becomes far-reaching and insistent. The horn is made in four sizes, some one of which will be found suitable for any size of motor. For cars which are so constructed that there is not room for the horn at the rear of

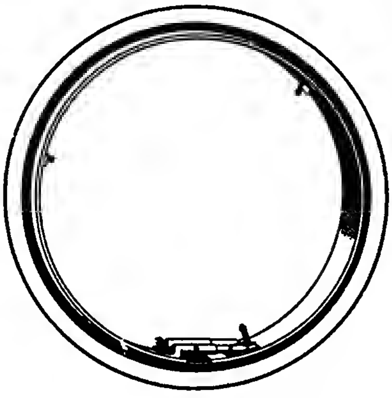


SPECIAL DESIGN OF JERICHO HORN

the muffler a special design is made in which the connection requires the use of a cut-out; otherwise the horn is on the same principle. The stem of this horn is threaded with one-inch standard pipe thread, and fits the standard cut-out devices. The non-clogging feature and the unique tone make this an ideal horn.

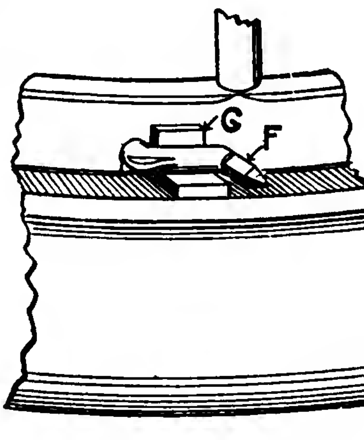
Crawford's "Special" Oil—The William J. Crawford Company, 14 Wood street Pittsburg, Pa., has put on the market a brand of oil under this name specially adapted for automobile use. It is a light-colored, filtered, pure mineral oil, with high viscosity, flash and fire tests, and is claimed to give good lubrication with a minimum of carbon deposit. Another brand is made for steam cars. The oil is put up in barrels, half-barrels and cases, with freight prepaid in the East and in the Mississippi Valley. The prices are especially reasonable.

Doolittle Demountable Rim—This addition to the ranks of the demountable rims is built on a new principle, which seems to have several features of merit. The rim is made in a single piece, but is sawed right across. To place it on the wheel the sawed edges are forced apart, expanding the rim so that it slips over the felloe and then is drawn together,



COMPLETE DOOLITTLE DEMOUNTABLE

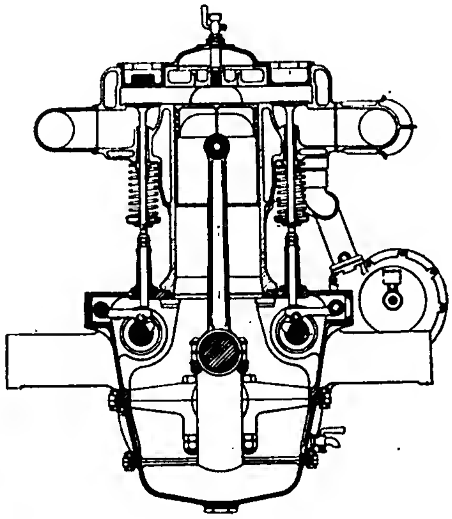
contracting it and setting it tightly into place. The expansion and contraction are effected by means of two turnbuckles, placed side by side and operated at the same time by a double-socketed ratchet wrench. To make it additionally secure two other locks are provided, as shown in the cut, in which F is the locking arm and G the side stop. This construction also facilitates removing the tire from the rim. It is impossible for the rim to



DETAIL OF DOOLITTLE RIM LOCK

stick to the wheel from rust or other causes, as the turnbuckles expand it with a force which immediately loosens it. The turnbuckles are enclosed in telescoping sleeves, so that they are not exposed to mud and dust, and the wheel as a whole presents a very neat appearance. The rims are sold in sets of five, the extra one carrying a fully inflated tire ready for the road.

New T-Head Motor—Since the modern tendency is toward specilization, many automobile firms are now buying their engines from an engine specialist. A newcomer in this line is the North Ameri-



SECTION NORTH AMERICAN MOTOR

can Motor Corporation, 79 Broad street, Stapleton, Borough of Richmond, New York City, with a motor called the North American. This is of the T-head type, which has gained much favor of recent years, due to the fact that it allows of very large valves, which, in turn, permit of very high and very low speeds. This makes a very flexible engine. As in this item, so also in others, the engines, two in number, are right up to date. The two engines now built are both of four cylinders, the sizes being 4 by 4 1-2 for low powers and 5 by 5 1-2 for higher powers. Other sizes can be made to special order, and, in fact, these two motors can be had in six-cylinder form if desired. An especial feature to which attention is called is the arrangement of the crankcase. This is divided into three compartments, the upper carrying the supporting arms, and to which the cylinders are attached as well as the crankshaft bearings. The next section below that is really but an intermediate section, although it carries the lower halves of the shaft bearings. Below that in turn is the bottom section, which really is but an oil pan. Drain cocks are provided to drain off the oil and, in addition, several large plugs which allow of emptying the pan very rapidly. When emptied of oil, the removal of about a dozen small bolts permits of removing this, in which case it serves as a hand hole or inspection port. This construction allows the running of the engine with the oil pan removed, so that trouble can be instantly detected.

Between the cams and push-rods are interposed small levers which take the thrust and are removable from the exterior.

INDEX TO ADVERTISERS

VOL. XXI NEW YORK—THURSDAY, JULY 29, 1909—CHICAGO No. 5

THE AUTOMOBILE

Glidden Tour nearing Finish

Greeted by a "Prairie Schooner" in Colorado.

Ready for the night's rest at Council Bluffs

Where Nebraska Quicksands were Treacherous

Substantial Western Hospitality

HUGO, COL., July 27—Thirteen of the thirty cars which started from Detroit on the morning of July 12 in the Sixth A. A. A. Tour to-day renewed the struggle with perfect scores: twelve others are in a more or less penalized condition; and five have been withdrawn, though three are still participating as non-contestants. Four running days remain, during which 740.5 miles are to be covered of the 2,643 grand total mileage. One of these four days—the final one from

Entering Denver, the Extreme Western Limit of the Tour, at the End of the Week's Run from Minneapolis

Salina to Kansas City—is said to be the hardest of the entire tour. This day is looked upon as the one which will send some of the clean score contingent to the hands of the technical examiners with blemished records, though it is most probable that this concluding looking-over by the experts will prevent any such thing as a tie for any one of the three trophies. This is the list of unmarked cars which this morning started for Hugo, Colorado:

GLIDDEN

No. 1 Premier (Jay).
No. 2 Premier (Hammond).
No. 5 Marmon (Marmon).
No. 6 Maxwell (Gager).
No. 8 Pierce-Arrow (Dey).
No. 9 Pierce-Arrow (Winchester).
No. 14 White Steamer (Searles).

DETROIT

No. 51 American Simplex (Woods).

HOWER

No. 101 Moline (Wicke).
No. 105 Chalmers-Detroit (Machesky).
No. 108 Pierce-Arrow (Williams).
No. 109 Pierce-Arrow (Schofeld).
No. 114 Lexington (Moore).

Denver has given the party a wealth of entertainment, and the program has been diversified, well planned, and carried out. The Denver Motor Club appointed committees which have been on their job ever since the grime-complexioned tourists Saturday last entered the hospitable confines of this energetic city of the Rockies, and if one had complaint to file it, would take note of the fact that the hosts were determined that the good things provided should not pass unheeded. Of course the visitors had to be shown what a first-class city looked like, this happening the greater part of Sunday; next came the banquet in the evening at Lakeside; on Monday followed the trip to Mt. McClellan, where a grand view of the Rockies unfolded itself, and in the evening was a finale at the rooms of the club.

Fording a Stream That Intersected the Colorado Prairie

Second Week Was a Hard One

The second week of the tour was considerably harder than the first one in that the cars had six days of steady going, covering 1077.2 miles at approximately a 20-mile schedule for the class A or big cars. The route was over dirt and gumbo roads, with not a drop of rain, hot weather and dry roads being the standing order for all six days. Dirt roads generally mean good roads in dry weather with plenty of dust, but the Glidden army met miles of bad dust roads, with deep ruts, waterbreakers, and high culverts that tested springs and shook tonneau occupants to desperation. For the first time in a Glidden tour, three of the daily trips have exceeded the double century mark, and a fourth was within four miles of the 200 mark.

It was freely predicted that the second week would be the real car tester, but such was not the case, and the cars made a better showing on the six days of the second week than they did on the five of the opening one, and besides traveled 1077.2 miles as compared with but 822.8 on the first week.

In all seventeen perfect scores out of the thirty starters have gone, leaving an unlucky thirteen to face the four-day eastward leg to Kansas City. Of the seventeen penalized nine were in the first week and only eight in the second week.

The past week saw four Glidden perfects go, namely: Frank Wing's Marmon, O. P. Bernhart's Jewel, A. Y. Bartholomew's Glide, and Buse's Thomas.

The Glidden ranks suffered more last week than did the Hower contingent, and the week proved a veritable Waterloo for the Detroit trophy class in that two of the three lost their clean standing. But two perfect-score Hower contestants lost out, Molines Nos. 100 and 102; and in the Detroit class the two losers are Bemp's Chalmers-Detroit and Waltman's Premier.

The troubles that arose last week in a majority of cases were of a different nature from those of the preceding week, and undoubtedly were the result of the continued knocking the cars received from day to day, whereas those of the opening week were in the majority of cases the result of an extreme incident which might be termed a minor accident. One example will suffice. During the present week three perfect scores have been lost due to breaking or leaking of the gasoline line. One was due to the gasoline pipe rubbing against the apron, another to a loosened flange, and a third to vibration.

The much-talked-of spring trouble at last appeared, though only one car had trouble in this respect, it being No. 10 Glide. Before the run it was decided that spring breakings would be legion, but the exact opposite is proving to be the case. Heretofore spring breaking has been a factor in car troubles, but not so this year, and it is reasonable to assume that the experiences of former years have proven a benefit. There have been a couple of cases of bolts breaking in wheel hubs and other cases of nuts on these bolts coming loose and new bolts being used. This is undoubtedly due to continued road use.

It is interesting to note that of the nine cars that were penalized during the first week everyone of them excepting the No. 112 Mason had additional penalties added during last week. This is an expected condition, and the Mason exception may be explained in that its penalty on the opening week was simply for breaking a pet cock.

The honors of the tour so far go to the Pierce entry of four cars, all of which are running with perfect scores, and the majority of which have trailed the chairman's car into the night stop nearly every day. The Pierce is the only multiple entry—an entry of more than one—which has a 100 per cent. perfect score standing. There are, however, several cases of individual perfect scores standing where makers entered one car and which is still perfect, examples of this being White, American, Simplex, and Lexington. Several of the entrants of more than one car, while not 100 per cent., are in good shape. Two of the three Premier entries are perfect; two out of the three Chalmers-Detroits are perfect. One of the two Maxwells remains perfect, as does one of the two Marmons.

The thirteen perfect score cars have been making remarkable running from day to day. The majority of them are first in at the checking stations, and they are often away early in the morning. The Lexington has been an early arrival at the night stops, the Pierces have generally been well in the van, and the Premiers have been well up, but the drivers have not been taking any chances. The Moline cars generally keep well bunched. The White has been run conservatively from the start, going out well toward the last end of the cavalcade each day, and not checking in much ahead of the scheduled time.

Pullman Train Where the Tourists Ate and Slept

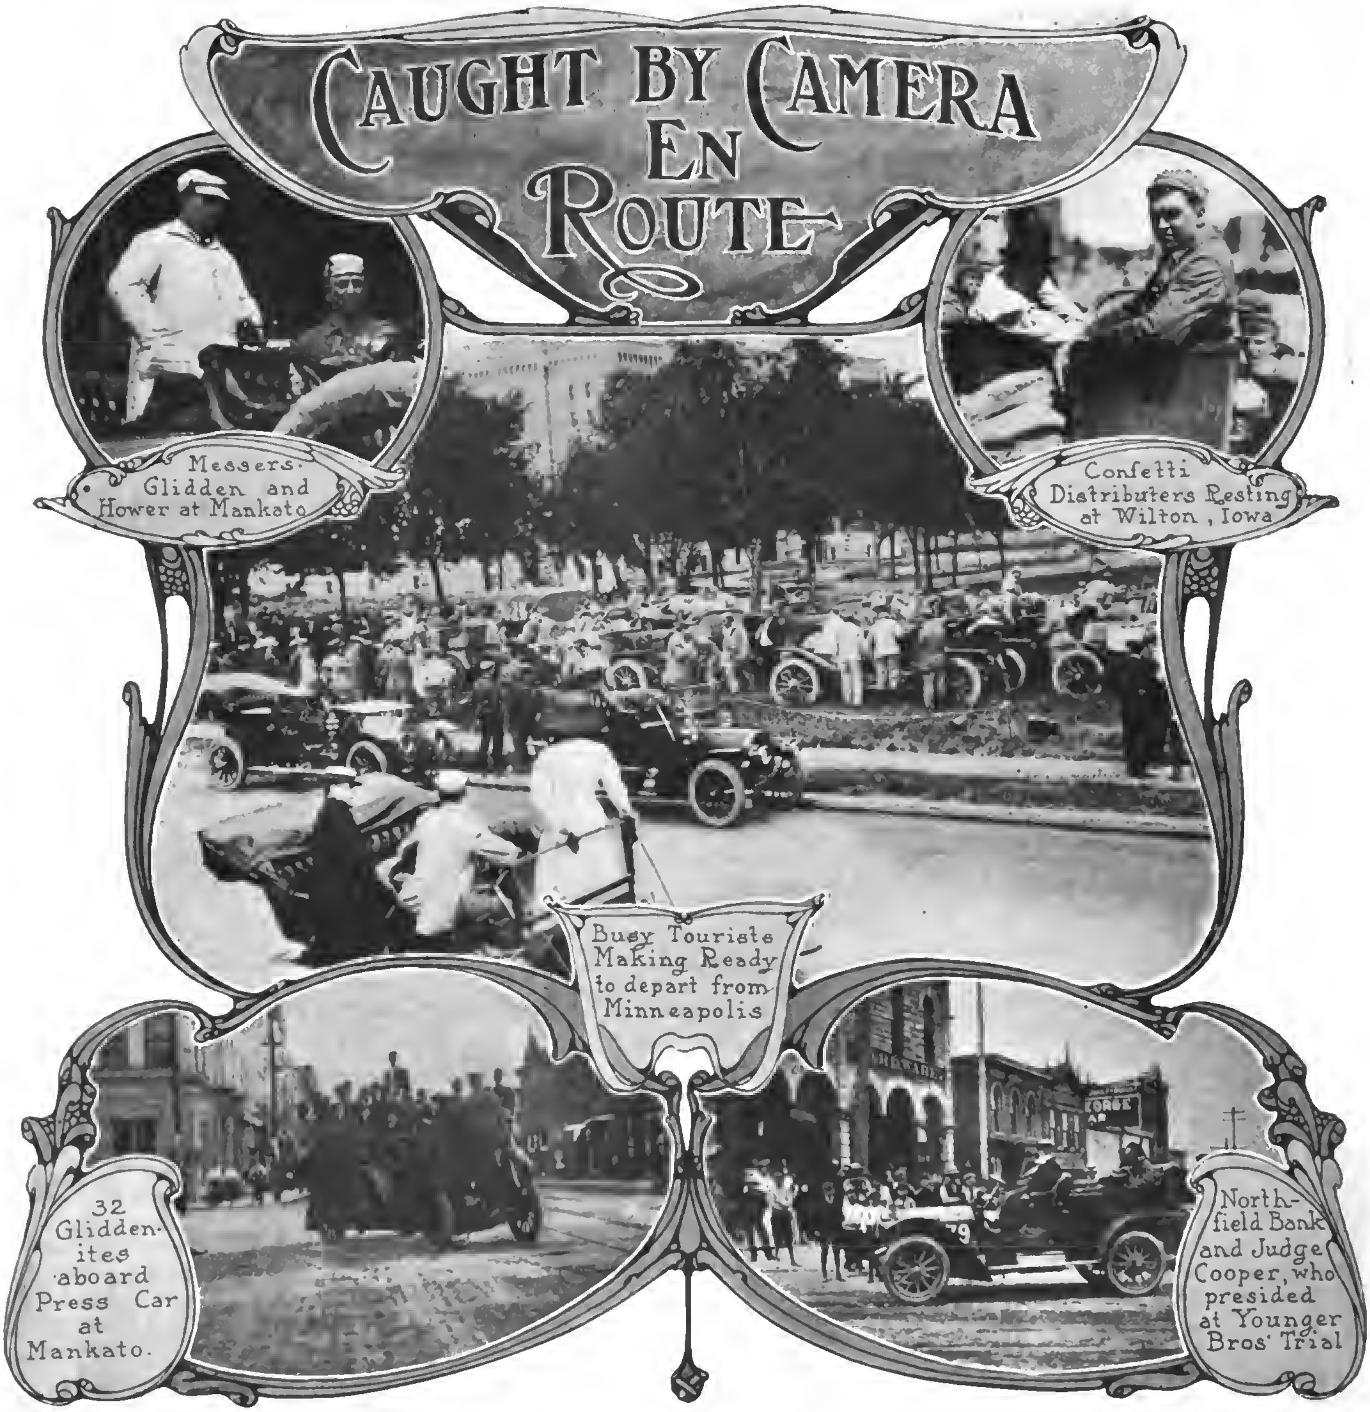
NOTED ALONG THE WESTERN TRAIL

At a Little Colorado Town, consisting of a store and two or three houses and unlimited prairie land all around, named Bignell, the press car stopped. Immediately the dozen inhabitants were about the car. "Our town," said one, "is but a few weeks old, but come back next year (somehow these boomers in the West like to talk one for themselves all the time) and we will show you a town of several thousand people." When asked in regard to the name Bignell, a genuine cowgirl on horseback, if ever there was one, modestly said that the city—she called it so—was hers.

In a Town 50 Miles from Kearney an old man reverently laid his hands upon a press car, stepped back, and said: "My, but I wish they had had those when I was young. You fellers look healthy. I was that way when a man kicked me out of the side door of a Pullman car twenty-five years ago, and here I am. I've never been away since." All of which goes to show that some fellows stick close to locations that are forced upon them by circumstances.

The Three R's, reading, 'riting and 'rithmetic, enter into some of the daily paper stories from the tour. The press men know from reading what their papers want; they know how to write; and the multiplication does the rest. Incidents are frequently magnified and sent broadcast over the country to worry the folks of the men most interested.

The Prairie Roads in Some Sections Had Bridges That Required Repairs Before Risking Passage—Simplex on Bridge



DAILY PROGRESS FROM FORT DODGE, IA., TO HUGO, COL.

MORE strenuous work and a settling down to the reality that it was a contest, not a pleasure jaunt, marked the third and hardest week of the tour. Passing through but three States, the tourists saw considerable change in the road surfaces, which changed for the worse, and a particularly noticeable difference in the elevation, a rise of about eight feet per mile marking over half of the distance traveled. While the penalties were few, still a number of cars were taken out of the perfect class.

EIGHTH DAY—FT. DODGE TO COUNCIL BLUFFS

(196.0 Miles)

COUNCIL BLUFFS, IA., July 21—Despite two detours which swelled the mileage somewhat, and an advance alarum that the run would be a "sockdologer," the journey here from Fort Dodge was accomplished almost without a whimper from the sturdy motor travelers. The 9 hours 42 minutes schedule allowance proved more than ample for all concerned. It's a fair guess that the two-car delegation from the Council Bluffs Automobile Club, which went to Fort Dodge to escort Pilot Lewis in his confetti strewing, underestimated the capabilities of the present tour participants, and mayhaps they did not give sufficient credit to the really excellent roads contained in to-day's route. While there were occasional stretches that were not strictly first class, and grades now and then intruded that caused the use of secondary speeds, the highway averaged as a whole better than anything yet met with on the tour.

Before departure from Fort Dodge, Pathfinder Lewis received a letter from Henry Haag, an autoing good roads enthusiast of Jefferson, who wrote as follows:

"It is a hard matter to make good roads when the weather conditions are constantly against us. However, I have made a special effort to have Greene county roads good for the Glidden tourists. The entire 35 miles through Greene county have been gone over several times with the big grader, and I have been over the roads repeatedly in the past week, filled all the approaches to bridges and culverts and fixed all the bad places. I have a full force out to-day for the final smoothing, and I believe you will find the 35 miles as good, if not better, than any other stretch of 35 miles in the State. We want to do all we can to make your trip through our county pleasant, safe and fast."

It is safe to say that every car to-day put in its best licks over this 35-mile stretch, and they were sorry when it came to an end. As the flying procession passed through Jefferson, only a couple of the cars took time to stop and express appreciation to Mr. Haag for his labors in their behalf, though all gave absent thanks later when they learned that he was the man responsible for their enjoyment.

Glidden was a sleepy sort of town which figured in to-day's route, and it was natural to suppose that there might be some "doings" when the trophy donor passed through. But when he did come along in Chairman Hower's car the only sight that the half-awake people of Glidden saw of Glidden was a streak of dust in the center of which floated an American flag. In consequence there is no mention here of what Glidden said to the good people of Glidden.

Originally to-night's stop was placed at Omaha. But that city is yet a dead one, as far as the A. A. A. is concerned, and the vigorous insistence of Council Bluffs, through its club member of the national body, made the selection of this hustling city an imperative proposition. As soon as the dust-caked visitors arrived in the public square, they were escorted to the Elks' club, where there was opportunity for exterior and interior washing. A band concert in Bayliss Park enlivened the finishing of the run, after which the entire party were conveyed to Lake Manawa for a good swim and a boat ride. In the evening came a banquet at the Grand Hotel, where in addition to Glidden, Hower, Lewis, and other tour notables, there sat Dr. T. B. Lacey, president of the Iowa State Automobile Association; Dr. Donald Macrae, president of the Council Bluffs Club, and W. R. McKeen, president of the Omaha Automobile Club. Of course there was speechmaking and compliments galore, and as a wind-up of the entertaining there followed a fine display of fireworks from the highest point in Fairmount Park.

Eight Cars Met with Penalizations—High speed was not conducive to the maintaining of perfect records, as it soon became evident, for the penalizations fell thicker and in more important parts than in any previous day of this tour. Eight cars were touched when the observers' cards were given full consideration, though none were late. All through the day the men at the wheel had been driving hard, with the expectation of finding terrible conditions ahead. In addition to there being so many marks scattered about, was the fact that six had previously been unsmirched. They were the Marmon, driven by Wing; the Jewel, driven by Bernhart; the Glide, driven by Bartholomew; the Premier, driven by Waltman, and the Molines, driven by Van Der Voort and Gregory. The other two cars which had received penalties before to-day were the Chalmers-Detroit touring car and the Jewel roadster.

The Chalmers was given 19.1 points, divided as follows: 1.6 points, for a new connecting rod bearing; 2.9 points, for inspecting two crankshaft bearings; 14 points, for labor in putting in the new bearing, and .6 point, for the use of an outside tool, a socket wrench. For tightening the hub flange bolts, and the material used—bolts—the Jewel touring car, driven by Bernhart, was given 16 marks. The Glide touring car, with Bartholomew up, had to have its steering arm repaired, the penalty being 8 points for labor and the same amount for material, the total being a loss of 16 points.

When the Premier toy tonneau car was penalized .8 of a point for labor connected with slipping a hose over a leaking gasoline feed pipe, it was the first of the Detroit trophy trio to receive a penalty. The pipe had chafed on the dust pan, and inasmuch as the piece of rubber used was taken from the gas lamp connections, no marks were given for material.

In the Hower trophy class there were three sets of marks, two being against the Molines, which had a three-car perfect team until then. The car driven by C. H. Van Der Voort had to open its crankcase to remove a piece of steel which was making itself heard, and the labor required 31 minutes, consequently a loss of 3.1 points. The other car, driven by Gregory, was stopped to replace a taper pin in the camshaft gear hub, and to replace a cap screw in the water inlet flange, the total points being 16.1. The third Howerite to have additions made to its

Fort Dodge, Iowa, Turned Out En Masse to Greet the Gliddenites on Their Arrival in That Hustling Burg

W. C. Marmon Assumes the Role of Good Samaritan

score was the Jewel roadster, which had an encounter with a sand bank a few miles from the finish. A curve which was taken too sharply resulted in a dished wheel, a bent steering knuckle, and a broken spring clip. The total penalty was 8.4 points, which brought its record for the trip to 29.2 points.

NINTH DAY—COUNCIL BLUFFS TO KEARNEY

(200.2 Miles)

KEARNEY, NEB., July 22—"Alfalfaville" is the other name for this bustling little Nebraska city, which to-day gave a most hearty welcome to the "Gliddenites," for such is the designation of the participants in the big tour, as far as the inhabitants of the West are concerned. They may have heard of the A. A. A., read of Hower, and a select few may have knowledge of the fact that a Detroit trophy is involved in the three-sided contesting; but all know that one Charles J. Glidden has poked about the world most industriously with an automobile and has made the fact known to millions of people. And so the cavalcade, one and all, are spoken of as "Gliddenites," and such they will be to the end of the chapter.

According to the measurements of the rotund Lewis, it is just 200 miles and one-fifth from the Iowa town where we slept last night to this energetic burg, where a local club is in the process of formation and a nucleus of it extended courtesies that met with satisfied acceptance. The real prize of the festivities was the temporary installation in a local plumbing store of several shower baths which found quick patronage as soon as their location was learned. This committee deserves to have their names printed, and so they are herewith given in a thankful spirit: Joseph Wingard, chairman; Dr. G. H. Wade, Dr. A. A. Munn, G. R. Kibler, and Dr. John Cameron. At a smoker held in the city hall in the evening, Mayor Patterson presided, and Judge Oldham delivered a stirring address of welcome. Several "Gliddenites" added to the oratory, and all joined in the singing.

While Omaha took an interest in this morning's passage of the tour through its streets, it can't be said that any vast hilarity greeted the occasion, for the spending of the night in Council Bluffs had in it a distinct disappointment to the residents of the city nearest to the banks of the Missouri. Hills added to the beauty of the scenery in the vicinity of Omaha, but after a score of miles the country flattened out and thus it remained with variations not worth mentioning all the way here. Fremont had a circus, and many horse-drawn vehicles were moving townward, and there resulted an inning of excitement for some of the farmers. Not before on the tour were so many frightened horses encountered.

Cattle grazing along the highways became frequent, and now and then one caught sight of what looked like a real cowboy. The alfalfa fields extended on all sides, and corn grew in plenty, thus indicating the two principal crops of the section traversed. The roads averaged up exceedingly well—in fact, so well that the nine-hour schedule proved utterly inadequate to inconvenience the sustained speed of the contestants, who arrived an hour and more in advance of checking-in time, and then after an impatient crawling behind the pacemaking car, which to-day had "Sammy" Stevens in the chairman's seat. The ruler of the contest board was suffering from a weather indisposition that caused him to stick to the Pullman train, but he instructed the acting pacemaker not to reach Kearney until 4 P. M.; and Stevens always obeys a ruling. While there were roads that must be set down as poor, the average to-day came as a pleasant surprise, and especially enjoyable was the concluding score of miles.

This cleanly young city of Kearney appreciates the motor-driven vehicle, as is attested by the fact that over 200 of its 9,000 odd inhabitants are the owners of cars. This would give an average of an automobile for every 45 people, which would appear to be a record, though there is a story floating about to the effect that another Nebraska town of less than a thousand population has over a hundred autoists.

But the cars are beginning to feel the effects of the long daily runs and the meager attention permitted without penalization. In consequence it is more than likely that the official announcements will contain demerit points more plentifully than has been the case up to the present time. Those to suffer in to-day's run included two that had previously been in the perfect class.

Only Two Penalties Were Inflicted—In spite of the fine roads where, as yesterday, the cars might have been given a free rein, the result to-day was not nearly as disastrous to perfect records as was the trip into the Bluffs. Only two penalties were inflicted, and there was one withdrawal. A penalty which had especial bearing on the contest was that given to the Chalmers-Detroit competing for the Detroit trophy, because now there remains but the American Simplex in that section with its desirable goose egg. The car driven by Cliff Waltman developed trouble with its commutator shaft connections, and tightening these gave it a penalty of 5.8 points for labor. An addition of .2 was made for work in tightening a motor bolt. The Detroit class is now ranked according to score as: American Simplex, Premier, and Chalmers-Detroit.

The other daily account was with the Jewel roadster, which had to change a spark plug, the points being 1.4, of which the .4 is for labor. The Chalmers-Detroit touring car withdrew, its previous penalties of 225.5 being thus increased to 1,000.

A single diverting occurrence happened during the day, and that was to the big six-cylinder Thomas touring car, which is participating in its second Glidden. There was a mudhole about halfway between the two cities of starting and stopping, and though it was short, it was mighty. A bed of quicksand was hidden by the black clay, and most of the cars were able to cross by rushing, but the Thomas sang to its hub and it took block and tackle to get it out. Webb Jay did the pulling with his Premier, using the Rapid truck as an anchor for the block.

Starter Ferguson Checking Out No. 53 Premier

This car is driven by C. Waltman, and is contesting for the Detroit Trophy. H. O. Smith, head of the Premier Company, is seated alongside the driver.

TENTH DAY—KEARNEY TO JULESBURG

(206.2 Miles)

JULESBURG, COL., July 23—Nebraska's roads did not hold out on the second day for the entire route, and after getting out of the county of which Kearney is the seat, the highways fluctuated from one kind to another, finally becoming little more than a prairie trail. Acres of alfalfa stretched in all directions in and about Kearney, soon after leaving which was seen the post marking the halfway mark between Boston and San Francisco.

Both the Union Pacific railroad and the Platte River intermittently paralleled the route, and the wide stream was crossed near Gothenburg over a bridge a mile long. The river is shallow and mostly mud-bottomed, but it and its two forks are invaluable for irrigating purposes and rescue thousands of acres of land from disuse. As an indication of the country included in to-day's run, it is only necessary to refer to one of Dai Lewis' route-book notations, where, at 76.6 miles, he called attention to 14 mail boxes at a turn where it was impossible to see a house.

Kearney, Nebraska, Which Is Half Way Between Boston and San Francisco, Greeting the Tourists

Of course, good-sized towns were discovered now and then, but in not a few instances they were often forty miles and more apart. North Platte had a single auto agency, but on a basis of population there is a substantial number of owners.

After about a hundred miles of the 206.2 had been covered, the going for the most part consisted of what looked nothing more than paths through pasture land, the center of the road being grass-sown. Rabbits frequently scurried across the front of the cars, quail popped into and out of view, and gophers were disturbed in their sunning. Occasionally patches of wild flowers enlivened the otherwise rather monotonous landscape, which, it must be confessed, bore a desolate appearance in the open country, and only fifteen towns were passed through in the two hundred miles.

Near Sutherland several sandy and steep grades exercised the full horsepower of some of the cars. Here one of the confetti craft suffered a strain that caused a stop of a couple of hours, while in several other instances the aid of a good team was enlisted.

The story had been current the night before that Ogallala intended to do some "trapping" in case the speed law was not respected. Pilot Lewis investigated the tale and found out that it was fiction. Nevertheless, there was an incident at Ogallala which involved No. 7 Jewel, "Ollie" Bernhart driving, and, apparently, a new owner of a Ford. The latter became rattled and there was a collision. It naturally followed that the visitor must be to blame, and so a telephone to Brule, the next town, resulted in the holding of the tour driver until the arrival of the sheriff in an auto. Realizing that the placing of the blame would be more trouble than a settlement for alleged damage, Bernhart told the sheriff to telephone back that his company would foot the bill after the repairman had completed his estimate. This closed the affair for the time being.

Once to-day the round-the-world experience of George Schuster, who is driving the Thomas Sixty which carried the editorial complement of THE AUTOMOBILE and *Motor Age*, came into play. Near North Platte, an amateur owner had slid into the ditch in giving too much of the road to the contesting cars. The right kind of a knot and a pull soon made one man a happy individual again, to say nothing of those he was transporting. This is the third job of the kind in which the Thomas has participated since the beginning of the tour.

This night stop finds the tourists most comfortably located in their Pullman train in the outskirts of this little Colorado village of scarcely more than 1,200 souls, and as this story is finding form, a cooling breeze is filtering through the car window, assuring a good night's sleep in an altitude that has increased to-day about eight feet with every mile traveled. On arrival, the local entertainment committee presented each tourist with a brilliant red badge, welcoming them to Julesburg, "The Gateway to Colorado," and further conveying the information that "We have Julesburg reservoir, capacity of 1,200,000,000 gallons; 28,000 acres of irrigated land that produces 20 tons of sugar beets, 200 bushels of potatoes, and 5 tons of alfalfa. Unirrigated wheat and corn lands pay for themselves with one crop."

None of Perfect Scores Disturbed—In the matter of penalties, that sinister report to which the contestants look each day to see how they fare, there were few. Perhaps any derangements of the day will appear to-morrow, as is frequently the case. There were three cars which have raised their numerical standing, none of them being among the perfect contenders. They were the Jewel touring car, driven by O. P. Bernhart, which lost .1 of a point for work in fixing a bent fender, sustained in its Ogallala collision; another was the Glide which replaced a spring, and its 9.2 points were divided into 5 for labor and the remainder for the new spring, and the third penalty was given to the Moline driven by Gregory, which had to fix a fender, the work being rated at .8 and a new bolt at .2 points. There has been some question as to the reason for such heavy penalties for fender troubles, and the authorities have answered

A. Y. Bartholomew Driving No. 10 Glide, at Kearney

that there is perhaps no part of an automobile which has more effect upon its appearance than its mudguards. To make these sufficiently strong should be an aim of the manufacturer, say the rulemakers.

ELEVENTH DAY—JULESBURG TO DENVER

(204.8 Miles)

DENVER, COL., July 24—There was much variety in the double century of to-day, though for the most it related to the living things seen in the prairie section of the run. For the first hundred miles, the route paralleled the South Platte river, with the shallow stream visible little of the time. Its irrigating ditches constantly reminded one of the immense value of this unpicturesque river, for fields stretched in all directions which benefited from its water, sugar beets being, perhaps, the principal thing grown. At Sterling, the largest town passed through, a mammoth sugar-making factory told the resultant story of the reclamation of former arid acres. Cattle grazed by the hundred, and most of the so-called towns were nothing more than livestock runways alongside the railroad tracks, which stuck close to the highway.

At Fort Morgan, which has a prosperous appearance, the plunge was made away from the semblance of civilization, and the long, hot and dusty ride began across the prairie. For a while the effete Easterners enjoyed the wide expanse of country and cussed the intervals of rut-infested trails. Then Old Sol got in his work good and strong, and one lost interest in the scamperings of prairie dogs and jack rabbits, the alarmed soarings of the meadow larks and bobolinks, and the killing of an occasional snake. Some of the touring party saw many other things that had life, the list embracing antelopes, coyotes, owls, hawks, quail and minor birds in great quantity. The monotonous landscape had frequent colorings in patches of sunflówers, wild asters, and white primroses.

The "roads" were many and complex, and it required the exercise of no small skill on the part of Pilot Lewis to lay the route and for those who came behind, to follow it. Every few miles it was a necessity to open wire gates, which were always closed again, as there is a fine in the State of $500 for failing so to do.

Moreville—it needs considerable more to make it a place on the map—consisted of a shaft which the optimistic prospector has started for the bowels of the earth in search of coal. Even he was not in evidence to speed the passing guests, who at the moment were laboring over one of the roughest stretches navigated during the day.

Soon after leaving Fort Morgan eyes had been strained to catch the first glimpse of the Rockies, and those with imagination saw the mountains many miles in advance of the less far-sighted. Clouds mercifully shifted about and frequently lessened the rays of the sun, which about midday supplied scorching heat. As a matter of fact, the Rockies did not show to advantage to-day, and few appreciated their bigness until nearing Bennett, previous to which the worst bit of the run had been encountered in the way of a shaky bridge across a small rivulet. The first cars weakened the structure, and THE AUTOMOBILE and *Motor Age* Thomas broke through. Schuster had tackled harder jobs before, and the big "60" was quickly rescued from its temporary predicament.

In several spots the carelessness of the farmers had permitted the irrigating ditches to overflow, and progress through these places had to be made cautiously. Once the E-M-F pilot car got stuck in one of its investigations, but Meinzinger extricated it, and the "spaghetti" then took the contesting cars around the miniature bog.

The desolateness of the scene at times caused one to wonder how one could find any value in life with such surroundings, the mud huts presenting a woebegone appearance with no treeless adornment and invariably the next similar "home" was so far away as to be out of sight. Of course it must be a matter of existence, not living.

Nearing Bennett, some twenty-five miles from Denver, the country renewed its appearance of being habitable, but even to the city limits, trees were few and far between, only the cactus and sage brush showing signs of growth. Of people there were none.

About fifteen miles from the mile-high city, at a ford in a stream, were the first big party of welcoming Denverites in their automobiles, though a couple of newspaper cars had said hello at Bennett. From that point into the finish the roads and, later, streets were lined. Bombs were fired to announce the arrival of the contestants, one being fired when they were ten miles from

Surprising Prevalence of Automobiles Along the Prairie Route Demonstrates Their Growing Popularity

Denver, two when they were five miles out, and another as each one entered the city limits. To see that the preparations were well carried out, the tourists were met by the official committee, consisting of: Dr. Ralph L. Taylor, chairman; Joseph McDuffie, George Wahlgreen, Tom Botterill, T. J. O'Donnell, Judge Grant L. Hudson, E. E. Sommers, and Dr. E. P. Geggenbach. The entry was over the Mountview boulevard, and through City Park to East Eighteenth avenue.

Only Two Cars Penalized—In view of the hardness of the route, considered the most difficult of the trip to date, it was expected that the penalties would be numerous and heavy. There was much surprise, therefore, when it was learned that only two cars had received marks against their scores. One of these was the perfect-score six-cylinder Thomas, driven by Gus Buse, Jr. Out on the deserted plains it was necessary to make a repair upon the gasoline feed line, where it had worn through. One point was the result. The other car was the Glide, which broke a spring, and did not arrive until evening. All manner of dire stories had arisen as to its delay, from broken bridges to "lady" bandits, and the latter yarn found publication in a Denver daily.

The trouble at the bridge might have delayed many of the contestants had it not been understood that time might be taken out if the delay was so great as to make a car tardy. At the broken bridge each contestant was instructed to wait for the next car, and the observer took out time.

TWELFTH DAY—DENVER TO HUGO, COL.

(173.5 Miles)

Hugo, Col., July 27—En route to this little village of the prairie, 173 miles from hospitable Denver, a two-hour control was put into effect at Colorado Springs, so that the contesting tourists could visit the Garden of the Gods and other points of interest in the vicinity. The ride to the springs from Denver is credited one of the most beautiful, scenically, in the country, the route paralleling the rocks with a good road. Pike's Peak to-day was visible over 500 miles. Soon after leaving the springs, the plunge began across the prairie, which supplied all kinds of going, some excellent, and much proving more annoying than difficult. At this time nothing living was visible, not even a prairie dog. The elevation of this new and possibly booming town, is some four thousand nine feet above sea level, and it is cool and comfortable in the Pullman sleeping cars, which answer for hotel accommodations.

For amusement to-night, the party patronized a church ice-cream festival and danced. Everybody in the village attended, for the population does not much exceed 500. The run across the plains led to the loss of two previously perfect scores, one in the Glidden class and the other the only clean-record machine of the Detroit class. The former is the White Steamer driven by H. N. Searles, in which sand found its way into the lubricator pipe and necessitated a cleaning. The labor spent cost 2.2 points, and lateness from the same source, 16 points, a total of 18.2. This leaves six cars still with perfect scores, out of the thirteen starters.

The American Simplex was the most unfortunate car of the day, however, for it dropped into a deep gulley and had its steering gear and radiator seriously injured. The gulley was hard to see and several machines narrowly escaped dropping in, instead of turning with the ditch to a more accessible place. The car driven by J. A. Wood was travelling at a speed of about thirty miles an hour when the danger was seen, and quick application of brakes reduced to speed to fifteen. Block and tackle were necessary in order to get out, and then the steering gear had to be straightened, and it was found that the bottom of the radiator was stove in and leaking badly. The penalty for labor and grease used was 1.4 points, and though the car was sixty-one minutes behind its schedule seventy miles out, it was able to check in ten minutes ahead of time. The little Brush runabout, now a non-contestant, driven by Trinkle, turned turtle before reaching Colorado Springs. It was righted by some of the contestants and will rejoin the party when it has had its steering apparatus repaired. Near the same place the Hupmobile, another non-contestant, broke a connecting rod, and it will have to hurry to catch up with the procession.

Freight Crew Greeting White Steamer in Nebraska

The Glide touring car has been experiencing trouble with light springs, and its penalty for Saturday, the run to Denver, was to-day announced at 119.3 points, of which 113 were for lateness

No. 8 Pierce Under Sycamores at Silver Creek, Neb.

and the other 6.3 points for labor on the fan belt and front springs. The standing of this car for to-day has not been given out, but will be announced to-morrow.

The Jewel touring car driven by O. P. Bernhart, has had its score re-arranged, beating it down from 16.1 to 8.9 points. There had been a miscalculation in the penalty inflicted on the run from Fort Dodge into Council Bluffs.

John Williams' Pierce Arrow went into the same hole that brought the American Simplex to grief, but as he applied his brakes and swung about when he reached it the car rested in the sand bank on its front axle and afterwards pulled itself off. This washout was at the bottom of a declivity, so that the drivers could not see it until they were but a few feet distant. There were several other washouts on the way, but none of them were as deep or as hard to locate as this one, and nobody had any trouble with them. In two places the cars were forced to travel through the deep sand of dry creek beds, and they also met a stretch of two miles across the unbroken prairie, on account of the closing of a road. Otherwise the going was considered fairly good by the drivers, who, however, have become pretty well inured to rocks, ruts and bumps. Pike's Peak remained in sight until the caravan was but a mile from Hugo, and when it finally dropped below the horizon it was like losing a good friend.

Word was received at Colorado Springs last night that the Rapid truck, which left Denver on Sunday on an attempt to climb Pike's Peak, got stuck when two miles from the top and had to turn back. It is expected to arrive here during the night and to continue with the tour.

Little Brush Runabouts Plugging Along—The two smallest members of the tour are the little Brush runabouts, which found the contesting pace too severe for a single-cylinder machine. Since their withdrawal they have been running each day as non-contestants and making good. The drivers leave each morning about 5 o'clock, and it is rarely that the completing cars catch up to them until near the end of each day's tour. Inasmuch as the newspapers of the large towns and cities en route are carrying admonitions to "Watch the little gray cars with the black stripes," a large number of Brush owners have been seen along the route. Drivers Huss and Trinkle have been accorded an ovation throughout the trip for their determination, and for the way in which they handle the little runabouts each day. **J. J. Evans**, the Brush sales manager, sees to it that in each city there is a goodly amount of publicity forthcoming.

Along the Banks of the "Father of Waters"—the Mississippi River—as Viewed from "The Automobile" Car

SOME ODDS AND ENDS ABOUT THE BIG TOUR

Newspaper Men Who Have Stuck—Journalists are not always expected to undergo the hardships of real autoing, if the statements of the rocking-chair correspondents are to be believed. The complement which left Detroit is not unbroken, for there have been a number of changes, both of addition and withdrawal. Among those who have not taken the entire trip are: "Jim" Sullivan of the Boston *Globe;* E. G. Westlake, Chicago *Evening Post;* J. S. Patterson, Chicago *Examiner;* Dick Tucker. Minneapolis *Tribune.* Of course THE AUTOMOBILE and *Motor Age* staffs with their own special car have used it every day. Among the daily paper representatives who are on the job are: J. C. Kerrison, Boston *American;* H. G. Reynolds, Boston *Post;* "Jack" McNamara, Boston *Herald;* "Jack" Wade, Boston *Journal;* Guy Shields, Chicago *Daily News;* Pete Estey, Chicago *Examiner;* Walter Birmingham, Chicago *Inter-Ocean;* "Jimmie" Fulton, Chicago *Record-Herald;* W. S. Gilbert, Cleveland *Plain Dealer;* Frank Lowry, Indianapolis *Star;* J. T. Sullivan, Buffalo *News;* Chas. G. Steinhauer, Cleveland *Leader;* Harry Smith. New York *Times.* Joseph Alphabet Ryan is one of the chair-car tourists who appears every now and then.

Tire Men Well in Evidence—There are fewer makes of tires in the contest this year than formerly, but the ones represented have better conveniences than ever before, and factory men are along to attend to the wants of the contestants. Diamond tires are dealt out by L. K. Rittenhouse, assisted by George Davidson; Goodrich interests are in charge of W. O. Rutherford, aided by C. E. Bonnett; Morgan & Wright tires are looked after by Harry Clinton, who also keeps a supply of yellow kid dusters for use on boys in the cities; and Goodyear air bottles with the Rapid truck, are dispensed by W. Simons, T. P. Meyer, and James Carey. Ajax tires are used by the Brushes and the Maxwells, and inasmuch as each of these automobile concerns has factory officials en route, they attend to the pneumatic wants of their machines. There is another tire man along in the capacity of mechanic on Bemb's Chalmers-Detroit car. This is John V. Mowe, manager of the Buffalo branch of the Firestone Company, who is taking the tour as a cure for weight. His friends think that the cure is not working as it was intended.

White Steamer Pictures in Many Papers—Kerosene as a fuel for automobiles has proven an interesting point to those along the way who are always looking for something new and good. The White Steamer, driven by the former secret service man, H. N. Searles, is the one using kerosene, and it obtains its supplies at any country store. The fact that the car is in the contest, with a perfect score, is kept well known by R. H. Johnston, the wideawake advertising manager of the White Company. Mr. Johnston sometimes rides with the White and sometimes a la Pullman, but at all times he has his photographs and cuts ready for the papers in the cities visited.

Crops Have Been Better all through the West this year than for twelve years past, and the fall will find the farmers well supplied with money. "Their interest has been aroused in motoring by the present tour," said H. O. Smith, "and they will look at automobiles now. I am told that out in this section the people have talked of little else than the tour for the past several months, and therefore the interest in the cavalcade and the warm welcome." Others who participated in the tour were well pleased, as the publicity obtained along the route of the tour was not purchasable at any price.

Train Brigade Each Day—Predictions were made that as soon as the comfortable train of Pullmans was installed there would be a following by rail. This was correct, but there are few who do travel in the cleaner manner. Some of the tour officials, Hotel Manager Glen Fargo, and W. F. Smith, of the Maxwell-Briscoe Company, are the regulars. Then there are generally half a dozen tourists who take a rest. It is claimed that more of the tour has been seen this way than by going in the automobiles, for the railroad has been paralleled for many miles.

H. O. Smith, of the Premier, on rejoining the party, was more than pleased with the train arrangements. "I have had a good night's sleep," said he, "and I am greatly surprised to know that from the outset there has been no roystering on the car. Things seem to be quieter even than at a hotel where numbers of men are put together in the same room. On the train everyone seems to be on his good behavior, and I believe that the special train solved the problem nicely and that it will make this tour a great success."

C. H. Van Der Voort, of the Moline, says his company will have three entries for the Glidden tour of next year, regardless of the route decided upon. The three cars of this Glidden will be in the Munsey tour from Washington to Boston and return in September, and perhaps in the Flag-to-Flag tour in October. Mr. Van Der Voort is also preparing two cars for the Algonquin Hill climb. "I believe in contests," said he, while at dinner on the special train, "and shall be very active in the field from this time on."

Soothing Lotions for Sunburn in Demand—Throughout the trip to the plain country the tourists who did not burn under the hot sun of Iowa and Nebraska, considerably joked with those who did. When Denver was reached, however, all joking was laid aside and there was a large purchase of cold cream, cocoa butter, and other preparations alleged to remove the sting of alkali bronzing. Everyone in the cars, except those wearing actual sun-bonnets, felt the touch of the sun and dust.

Hower Has Daily Guests—The pacemaking Premier used by Chairman Hower and Trophy-donor Glidden is each day occupied, also, by some guest of the chairman. Sometimes he has newspaper men, once a tire man, and all the time Sam B. Stevens, of Rome, N. Y., a member of the contest board. "Jim" Sullivan, of the Boston *Globe*, and "Jack" Kerrison, of the Boston *American*, were elected on alternate days, and W. O. Rutherford, of the Goodrich Company, on another one.

Hupmobile in Non-Contesting Division—The "little Hup," as it is generally known, is now with the tour as a non-contestant, and is traveling each day with the main body of the cars or directly behind them. Since leaving Minneapolis it has been going along steadily and without any difficulty, crossing the sandy stretches, climbing the steep hills, and showing speed on the fine stretches. At present the Hupmobile is one of the three non-contestants, all from the smallest car class.

"Please Send Me Postal Cards!" was written on a lot of notes thrown into cars along the way. Away back in the Pittsburg tour of 1903 the high school girls of Chagrin Falls handed apples to the tourists from the end of fish lines, dangled from poles over the road, and one of the tourists got an address to which he wrote, and the result was matrimony. Perhaps some of the tourists of to-day may also be fortunate.

Vermont Autoists Represented by President Brown—From the Green Mountain State comes the president of its automobile association, W. W. Brown, who declares that he is just taking a joy ride, and is riding as a passenger in No. 4 Marmon. The amount of good roads in the West has been a surprise to him, as to most of the tourists, and he says that he will so report when he returns to New England.

Never Heard of Father George—Up in Minnesota there is a town called Morristown, and one of the tourists said to a native there: "Is this where George Washington had his headquarters during the Revolution?" The answer finally emanated—"Well! I think you must mean Morristown, Iowa, for I don't recollect having heard of anybody by that name living here."

Nels Hamilton, of Central City, Neb., was so enthusiastic over the tour that he walked many miles from his ranch to erect two posts out of corn stalks and stretch across the road a welcoming banner and a lot of American flags. The demonstration was appreciated, for there was not a house in sight for miles and miles out on that broad prairie.

Dwight Huss First Gained Fame by driving a little 10-horsepower single cylinder Oldsmobile tonneau car to St. Louis in 1904 at an average of 20 1-2 miles an hour, and now Huss, contrary to the usual rule, has taken up a car of even smaller horsepower, the 7-horsepower Brush. "I drive this because it is worth my while," said Huss with a smile.

Charles J. Glidden Has Not Abandoned his around the world journey, but will renew it very shortly and complete it in 1911. Mr. Glidden will then have driven fifty thousand miles, and his book will contain two hundred thousand words and illustrations galore.

"I Sort of Like This Party," said a veteran journalist who has been on every big tour. "Why, there are no hard feelings that I know of in the 'bunch,' and everything is so pleasant that it reminds me of other tours—for the reason that it is different."

Church Steps Are Crowded frequently with people, but there is a noticeable lack of smiles when the tourists almost invariably shout: "Waiting at the Church?" It soon became evident that this worn-out song has not yet invaded the West.

All Along the Route to Denver local people seemed to like to supply what is known as a "scare," and every day's run was faster, as every driver beat it trying to reach the bad roads early, then only to find no really bad roads.

MITCHELLITES IN CALIFORNIA CELEBRATE

San Jose, Cal., July 26—Mitchell owners from all over the State gathered in San Jose for the third annual jubilee of their "family." The day was perfect, and the roads in almost every instance were reported in the best of condition. The principal event of the jubilee was the hill climb over Alum Rock Hill. The course was a mile long, a steady grade of 8 per cent., with an almost perfect surface. Miss Marion Walcott won the ladies' class, in the fast time of 1.19 4-5. The fastest time, 1.06, was made by L. P. Brassey, in the old model class. W. M. Lewis and Vernon Rogers, of the Mitchell Company, were present and handled the details.

POPE RECEIVERS FINALLY DISCHARGED

Newark, N. J., July 27—Vice-Chancellor Howell to-day officially discharged the receivers of the Pope Mfg. Co., and ordered them to turn over the balance of cash on hand, amounting to $7,598.87, to the officials of the new company. This ends the receivership and completes the reorganization of the Pope Mfg. Co.

Building an Aeroplane in Newburgh, N. Y.—That stonecutters may fly is the belief of David Lowers, a stonecutter, and his son, David M. Lowers, who are building an aeroplane in the city on the Hudson, and which has given evidence of its ability to navigate the air. The machine is now being completed and will be equipped with a 30-horsepower engine. New ideas in steering and in the distribution of weight are features.

CURTISS FLIER STILL IN REPAIR SHOP

Mineola, L. I., July 26—Glenn Curtiss' aeroplane, which flew so successfully last week, only to be wrecked by a novice, is still laid up. It was expected that Curtiss might have it ready for further tests to-day, but the damage was found greater than at first supposed. When the canvas was removed from the skeleton framework it was found that twenty-nine of the forty ribs had been broken, and there was also considerable injury to the running gear. However, it is hoped that it will be in shape Wednesday. Mr. Curtiss will try to better his present record of 52 minutes 30 seconds before leaving for Europe to contest in the international races at Rheims, France.

FRENCH AEROPLANES WRECKED BY STORM

Vichy, France, July 25—A violent storm wrecked the aeroplane sheds here to-day and scattered a great crowd which was present at the grounds. Paul Tissandier's Wright aeroplane was demolished, and M. Paulham's Wright and the machines of MM. Zipfel and De la Rue were much damaged.

MORE PRIZES OFFERED FOR AVIATORS

London, July 25—Baron de Forest has offered a prize of £4,000 for the first Englishman to cross the Channel on an English-built aeroplane, provided he beats the existing record in time. William Waldorf Astor has contributed £1,000 to the national airship fund held by the *Morning Post*.

Bleriot Starting Across the Channel from Sangatte Cliff on His Epoch-Making Flight

DOVER, ENGLAND, July 25—Louis Bleriot this morning flew across the English Channel from Calais to this city in his monoplane. The distance is about twenty-four miles, and he was in the air thirty-seven minutes. The flight was accomplished without incident, and apparently with the greatest ease.

Bleriot left the Terminus hotel, at Calais, at three o'clock this morning and drove out in an automobile to Baraques, where his aeroplane was housed. As the weather seemed favorable, he ordered out the torpedo boat which the French government had assigned to him, and began preparations for the flight. The aeroplane, which is Bleriot's eleventh, was found in good condition; the motor ran smoothly and powerfully. At 4 o'clock he mounted his seat and made a short trial flight of a quarter of an hour, landing near the edge of the cliffs. There he waited for the sun to rise. The weather was foggy, so that the coast of England could not be seen, and there was a light southwest breeze.

At 4:30 Bleriot, clad in a khaki suit with a close-fitting cap, again climbed into the car. He had injured his foot several days before, and laid aside a pair of crutches as he took his seat. Anzani, the designer of the motor, himself cranked it, and at 4:35 the aeroplane shot into the air. Bleriot rose rapidly to clear the telegraph wires strung along the edge of the cliff, and sailed out over the water at an elevation of about 250 feet.

The torpedo boat put on full steam and headed for Dover, but Bleriot, making over forty miles an hour, quickly passed it. In his own story, printed in the London *Daily Mail,* he says that after flying for about ten minutes the chalk cliffs on both sides and the torpedo boat were completely lost in the fog, and as he had no compass he was compelled to let the aeroplane take its own course. As a consequence the wind took him out of his way, and when the English coast became visible he made out Dover castle far to the west. He had to turn the machine almost at right angles. Now, too, the air currents set up by the cliffs began to be troublesome. This was by far the most difficult part of the trip.

However, he reached safely a green meadow two miles east of Dover, which had been marked with a big French flag as a suitable landing place. A sudden wind whirled the machine around, and Bleriot shut off the motor and descended sharply from a height of sixty-five feet. He struck the ground with a severe bump, breaking the propellor, but without harm to himself. Two Frenchmen who had been expecting his arrival were the first to welcome him and to help him from the machine. His injured foot gave rise to the report that he had been hurt in landing, but this was incorrect. An automobile quickly took him to Dover, where the torpedo boat, with his wife on board, had just hove in sight. Mme. Bleriot came ashore in a small boat, and the couple were heartily cheered.

A guard of police was necessary to protect the aeroplane from souvenir hunters, who would quickly have wrecked it and carried away the last fragment. As it was, the wings were covered with autographs. Soon the enterprising city officials erected a tent over it, and charged sixpence admission.

LONDON, July 26—Bleriot and his aeroplane reached here this morning, the aeroplane to go on exhibition and the aviator to receive the £1000 prize of the *Daily Mail* which he won by his flight. The prize was awarded at a luncheon at the Savoy, and Mr. Haldane, the Secretary for War, was the principal speaker. The Aero Club has decided to present M. Bleriot with a gold medal similar to that which it conferred on the Wrights. M. Bleriot received his honors modestly, and managed to stammer "Thank you" in English.

Bleriot and His Epoch-Making Aeroplane

Bleriot is a successful inventor, and has long been interested in the problems of aviation. Unlike Latham, his rival, he is of pure French descent, and is 37 years old. He is a graduate of the famous Central School of Engineering at Paris. In 1896 he invented one of the first practicable acetylene lamps, and Bleriot automobile headlights are now used the world over. He made his first full-sized model of an aeroplane in 1900, and for a long time it was kept in his factory at Paris. Since then he has spent much money and time on the subject.

Last year he attained his first noteworthy success in a cross-country flight from Tours to Athenay, the first of its kind ever made in an aeroplane, and a monument was erected in his honor. Quite recently he made another flight from Etampes to Chevilly, a distance of twenty-five miles. His record for time is 50 minutes 8 seconds, made at Juvisy July 4. When Latham failed in his recent attempt, Bleriot hastened to Calais to try the passage himself. He has always been noted for his recklessness, and it has been predicted many times that he would be killed; but although he has been in innumerable smash-ups and has wrecked half a dozen aeroplanes he has always managed to escape without serious injury. Only last week one of his machines caught fire and Bleriot's foot was painfully burned. It was this accident that caused him to be walking on crutches before he started.

The monoplane which performed so well is one of the smallest and lightest ever built. It is only about twenty feet across the wings, and weighs 400 pounds. The motor, which is a three-cylinder air-cooled design of 25 horsepower, made by Anzani, rests between the wings and carried the two-bladed propellor on the front end of its shaft. The propellor is thus the foremost part of the machine. A tail extends some distance to the rear, and carries horizontal and vertical rudders. The operator sits in a skiff-like body between the wings, and to the rear of the motor. In previous flights M. Bleriot was troubled by the hot oil from the motor which blew back into his face, but this defect has doubtless been remedied. Control is by a single lever, which moves backward and forward to turn the machine up or down, and sidewise for steering to the right or left. The wings can be

Bleriot Awaiting the Signal for the Start

folded up, if desired, and in this condition the machine can be towed along behind an automobile.

The aeroplane is popularly described as resembling a huge dragon fly. Its wings are covered with an opaque material like vellum, making them seem very light and fragile.

Experts here regard Bleriot's performance as a vindication of the monoplane type. The machine has much less surface in proportion to weight than is usual, which makes it more stable.

LATHAM AGAIN FALLS IN CHANNEL

DOVER, ENGLAND, July 27—Hubert Latham, whose gallant attempt to cross the Channel last week prepared the way for Bleriot's successful trip, was caught napping, literally as well as figuratively, and lost by a few minutes his chance to tie with Bleriot for the *Daily Mail* prize. The two aviators had agreed that if both made the flight the same day they would divide the prize, regardless of which was actually the first to touch English soil. When on the morning of the 25th he found that Bleriot had actually started, he made a desperate attempt to follow, but the rising wind compelled him to descend. He swallowed his disappointment as best he could, and when the news of Bleriot's landing was flashed across to Calais he sent back the message: "Hearty congratulations. I hope to follow you soon."

True to his word, Latham made a second trial this evening, and moreover announced his intention of continuing straight on to London, if he succeeded in crossing the Channel. A great crowd gathered on the cliffs and roofs of Dover when the wireless announced that he had left Calais. Presently those with glasses made out a black spot in the sky, approaching rapidly. It was Latham, and he seemed headed straight for the landing place that had been prepared for him. The ships in the harbor set up a terrific din with their whistles. But suddenly the machine faltered, recovered for a moment, then settled swiftly down on the water, still two miles from its goal. The aviator was picked up, wet through and with a bad cut on his head. The cause of the failure was the motor, which stopped for no apparent reason.

WRIGHT SUCCEEDS WITH PASSENGER IN OFFICIAL TRIAL

WASHINGTON, D. C., July 27—Orville Wright fulfilled the first part of the government requirements to-day by a flight of 1 hour 12 minutes and 40 seconds, carrying a passenger. Incidentally he broke his brother's best record for a flight with passenger, made in France last year. President Taft witnessed the trial.

During the early afternoon there was a high wind, and flight seemed impossible, but it suddenly dropped away within half an hour, and the sun came out and shone brightly. The aeroplane was at once brought out and placed on its rail. Lieut. Lahm, the passenger, took his seat, and a moment later Orville climbed in beside him. He gave the signal, and the car was released and shot away. It seemed to rise as easily as usual, despite the extra weight, and made a beautiful turn at the end of the field. As it passed the northern end of the field the crowd cheered, and President Taft looked on with interest.

The machine sailed on smoothly, a little lower than usual, but making its circuits with the regularity of clock-work. Only once the machine tilted badly in a sudden gust of air, but it easily righted itself and kept on. The performance grew almost monotonous. Lieut Lahm sat quietly in his seat, keenly watching the operation; apparently he spoke to the aviator at times. The colors of the brilliant sunset faded, and the half moon grew brighter. When the hour required by the government specifications had elapsed, the crowd burst into cheers, and the automobiles honked in unison. Orville waved his hand, but kept on. Ten minutes more, and they cheered again as Wilbur Wright's record was broken. On the next round Wilbur stepped out and waved his hat as the signal to come down. It was now quite dark and further flight would have been dangerous.

Orville was talking to Lieut. Lahm as they came down, and the aeroplane touched the ground before he had expected, bouncing up quite sharply and settling again fifty yards further on. No damage was done.

After the brothers had a talk with President Taft, who congratulated them and said that it was an honor to have been present. He laughingly hoped that Lieut. Lahm had behaved well and had not talked to the motorman.

The brothers were much pleased with the flight, and Wilbur estimated that the speed was about forty miles an hour. Tomorrow, if conditions are favorable, they will attempt the straightaway speed trial of five miles and return. The flight will be made in the direction of Alexandria, to the south of Fort Myer, and a small balloon will mark the turning point. Lieut. Foulois will be the passenger. To meet the requirements, the aeroplane must make a speed of thirty-six miles an hour, and a bonus will be paid over the contract price if this is exceeded.

Wright Aeroplane Again Breaks Skid

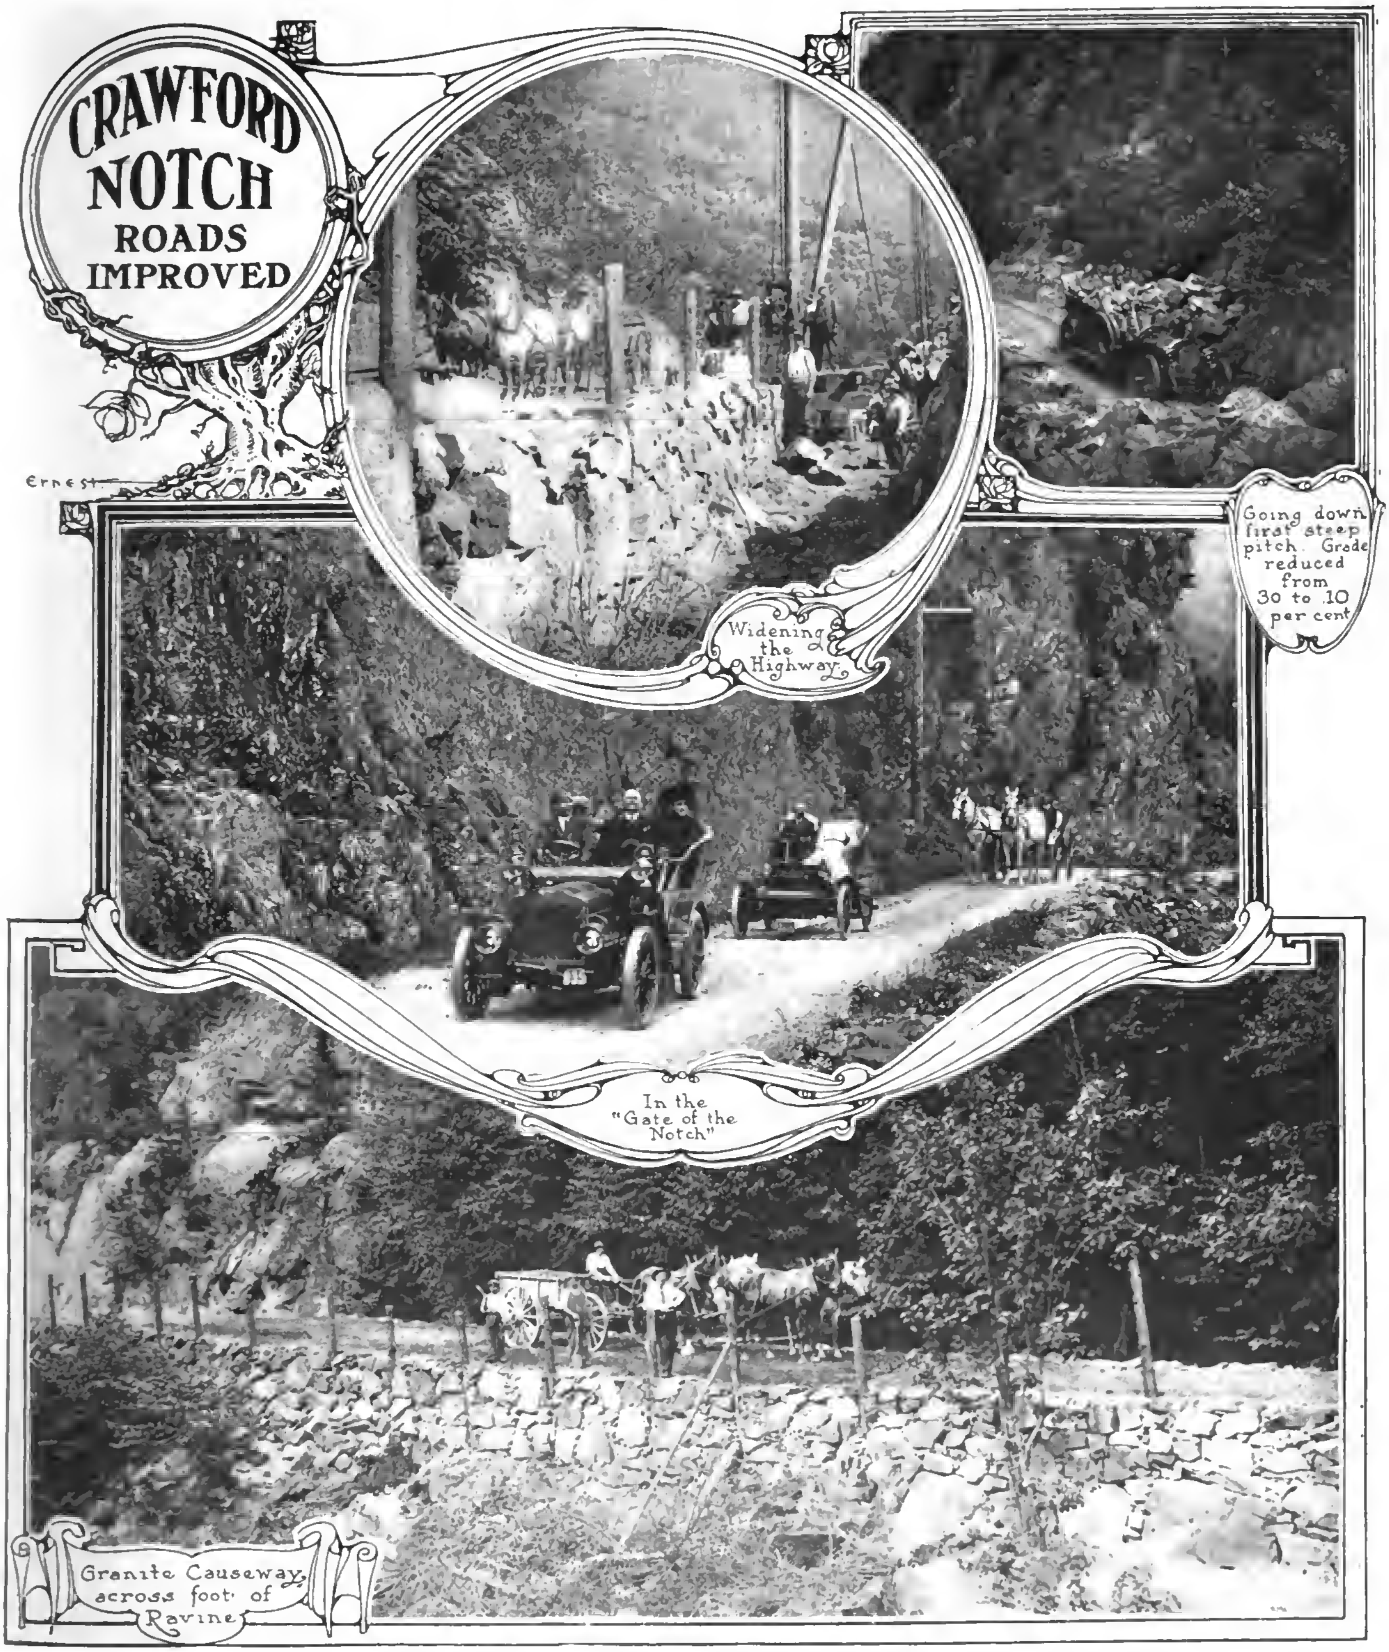
WASHINGTON, D. C., July 24—The Wright brothers had intended to take up one of the Signal Corps officers as a passenger to-day, but a vagrant gust of wind as Orville was alighting from a trial flight put an abrupt end to their plans. After a flight of twenty minutes the aeroplane was settling down when a sudden breeze caught it and brought it to earth with a crash, snapping the left skid. Repairs will be completed by Monday.

Last Wednesday a break in the machinery compelled a descent when the machine was speeding along at a forty-five-mile gait. It was on its third lap when a small object was seen to fall from it, and instantly the motor stopped. Orville glided easily down. The small object was found in the grass and turned out to be the magneto pinion. It was put back on its shaft and brazed in place, and Orville went up again. The next flight lasted only eleven minutes, but Wilbur announced that a speed of 44 miles an hour had been attained.

Orville Wright Flies in Taft's Presence

WASHINGTON, D. C., July 26—President Taft, Vice-President Sherman and a crowd of ten thousand saw Orville Wright fly this evening in the teeth of a eighteen-mile breeze. Aided by the wind, the aeroplane succeeded in rising from its starting rail without the use of the falling weight. It made three and a half circuits of the field; no time was announced. The President had a short talk with the brothers and examined the machine carefully. The flight was made for his especial benefit, although it had been first decided to postpone it on account of the wind. It was the first time the President had seen the machine in flight.

CRAWFORD NOTCH ROADS IMPROVED



Widening the Highway

Going down first steep pitch. Grade reduced from 30 to 10 per cent

In the "Gate of the Notch"

Granite Causeway across foot of Ravine

THE central pass of the White Mountains in New Hampshire, known as Crawford Notch, has always been noted for its scenic attractions. With the advent of automobile touring its fame became more widely disseminated than ever, with consequent benefit to those who live in the State, and those particularly who live near the fascinating routes through the high hills. The State has appreciated this fact, and to make automobiling easier, without lessening the grandeur of the surroundings, has made changes of a considerable nature in the roadways of that section within the past few months. Under the supervision of the New Hampshire Highway Commission causeways have been built, steep grades have been cut down, and roads have been widened wherever possible.

During the month of June the work was focussed in Crawford Notch, and notably in "The Gate of the Notch," where the ravine at the foot of the first very steep rise has been bridged by a granite causeway, reducing the grade from 30 to 10 per cent. This will be pleasing to all who tour there, for although the cars have generally been able to get up on their lower gears, or by rushing, they will not be so inconvenienced hereafter.

Under A. W. Dean, the State engineer, with George D. Howland of Crawfords, in actual charge of the work, the highway forces and the Maine Central railroad's derrick crew have constructed the highway-waterway-railway improvements. The loose rock obtained from widening the highway at the top of the pass and from the railroad dump was utilized in constructing large retaining walls for the highway on one side and the railroad on the other, allowing the water to flow between them. This gives a width of between 18 and 20 feet for the road, with occasional places where 15 feet was the limit.

ROAD BETTERMENT IN CONNECTICUT

Hartford, Conn., July 26—State Highway Commissioner James H. MacDonald has purchased a large quantity of crude oil and distributing apparatus, and in the very near future will spray sections of the main heavy traveled highway in an endeavor to render the roads of the Nutmeg State dustless and fit to tour over. The Commissioner thinks well of the oiling proposition, if properly done, and he has taken every precaution to see that Connecticut's oiled thoroughfares will be the best ever. When it is realized that it costs approximately $500 per mile to water a macadam highway and the treatment is of but temporary benefit only, it is obvious that two or three coats of oil judiciously applied in the course of a season would prove far superior. If after this exhaustive trial of the oiling system the results are not eminently satisfactory, some other mode of dust laying will probably be resorted to. Tar is an admirable dust layer, but little of it has been used as yet. The best illustration of the utility of a well-tarred road is afforded by the stretch about the Capitol grounds used almost exclusively by high-powered cars. This road was treated two seasons ago and the road to-day, for the most part, is in excellent condition and practically dustless at high speed.

The Commissioner is carrying out the Summer plan of road betterment as fast as possible. Two stretches in Manchester, and one of three miles along the old Albany turnpike, through the town of Bloomfield, are now receiving attention. The ferry road from Saybrook to the Lyme ferry, one of the most abominable stretches in the State, will shortly be improved, of interest to motorists using the shore route.

A fine stretch over Weatogue Mountain, one of the most picturesque sections of the State, has recently been improved. A long stretch through the town of Milford, a portion of the uncompleted link between the New York and Massachusetts State lines, and another short stretch between Greenwich and Stamford will soon be in first class condition. An excellent gravel road of three miles has just been completed in the town of Windham. The gravel roads of the State seem to have withstood motoring travel very well indeed, as for instance, that portion between the towns of Norwalk and Wilton, which is now in good condition, though it has been built twelve years.

BETTER ROAD AROUND NORRISTOWN, PA.

Philadelphia, July 26—Automobilists en route from this city to Pottstown, Reading and Harrisburg are beginning to use a comparatively new through route which goes around Norristown, Pa. Instead of running into the Montgomery County seat, approaching it from Chestnut Hill and Plymouth Meeting, the cars are continuing on the Germantown pike, joining the old Reading pike at the Collegeville Bridge over the Perkiomen. The usual longer route out of Norristown, over the Reading pike, is in very bad condition, the roads being rough and full of bumps, while the Germantown pike is in splendid shape. The Norristown Automobile Club has its house on the old road, and Harry B. Lasher, formerly a Philadelphia newspaper man, has opened the Fairview Inn, first established in 1732, on the new route. Both directions are equally fine for views of the beautiful Schuylkill and Perkiomen valleys.

ROAD CONDITIONS IN CENTRAL NEW YORK

The Automobile Club of Rochester is doing good work in its club publication toward keeping its members posted on road conditions and changes in Central New York. As many tourists are using the roads between Albany and Buffalo, it may be interesting to know some of the desirable changes. On the road from Syracuse to Geneva, for instance, a bad stretch of road through Seneca Falls and Waterloo can be avoided by taking the road north from Geneva along the New York Central Railroad tracks, about 3 1-2 miles out, turning east at right angles to Free Bridge. Going from Oswego to Binghamton it is advised that the south side of the river be followed. Between Little Falls and Fonda the road is being turnpiked. Road work is in progress between Chili and Churchville. As a detour it is suggested that tourists take the westerly road half a mile east of Chili and follow to the end of the road, turning to the left, which will eventually bring the tourist back on the main Buffalo road. All the roads around Albany are reported in good condition, and the entire route from Auburn to Syracuse is in fine shape.

SOME NEWS ABOUT NEW JERSEY'S ROADS

Some helpful information has been supplied to prospective tourists in New Jersey by the good roads observers of the New Jersey Automobile and Motor Club. Extensive repairs being made on the road between Fort Colden, one mile east of Washington, N. J., and its junction with the Hackensack and German Valley roads, about one mile beyond Hackettstown, have necessitated the closing of that road for automobiles until about October 15. Tourists visiting the popular Pompton Lake section will be glad to know that sections of the road near the Pompton station have been coated with oil, but care should be exercised in crossing the bridge near Mountain station. The bridge is being rebuilt and a temporary one is in use, red flags being placed on both sides of the temporary structure.

SPEED TRAPS UNPROFITABLE IN CANADA

Montreal, July 26—The small towns in this province have nearly all abandoned their speed traps, as the new automobile law has made them decidedly unprofitable. The law now provides that all the revenue from automobile prosecutions shall go to the province, and all municipal speed regulations are cancelled by the clause that speed shall be "reasonable" but not in excess of nine miles an hour in cities, towns and villages, and fifteen miles on the open road. Although the use of "reasonable" in connection with these limits may seem strange, the law has freed automobilists from all fear of petty persecution.

BUILD BRICK ROADS INSTEAD OF MACADAM

Pittsburgh, Pa., July 26—The Road Commissioners of Allegheny County have decided to build no more macadamized roads. During the past five years more than 300 miles of macadam has been laid in this county. However, the wear on the macadam has made the question of repairs very serious, and the commissioners now intend to resurface all the macadam roads with brick as fast as the top dressing wears off, and to build all new roads of brick on a concrete base. They believe that this surface will last twenty years without repairs. The initial cost will be about one-third more than for macadam, but the contractors are willing to guarantee no repairs for five years.

NEW BRIDGE TO BE BUILT OVER CONNECTICUT

Hartford, Conn., July 12—The Lyme bridge bill has now passed both houses of the Connecticut legislature, and to become effective but awaits the signature of the Governor. The new bridge, when completed, will relegate the old flat-bottomed ferry boat to oblivion, much to the satisfaction of motorists who have been compelled to use the craft. An issue of bonds will provide the necessary funds for construction.

Functions and Frailties of Motor Cylinders

BY THOS. J. FAY

LIMITING weight of the reciprocating parts is necessary, in order that the speed of the motor will be sufficiently high to afford power adequate to realize a high weight efficiency. Accelerating a considerable reciprocating mass will result in a loss of power, but the stresses in the crankshaft section are the most likely to demand a limitation of speed on account of inertia. It has been found in practice, under the several conditions obtaining, tbat pistons may be much lighter than would be indicated by superficial mathematical means ready to hand for use in determining tbe dimensions of sections.

Inertia of the Piston—For each square inch of piston area, the inertia will be as follows:

$$I = \frac{F}{a} = \text{inertia component, per square inch of piston.}$$

Amplified,

$$I = \frac{W}{a} = N^2 r\,(\cos\theta + a' \cos 2\theta)$$

and.

$$\frac{W}{a} = \text{weight of reciprocating mass in pounds per square inch.}$$

when, N = crank revolutions per minute.
θ = crank angle.
r = crank radius in feet.
W = effective weight of reciprocating mass.
a = area of piston in square inches.

The effective weight of the reciprocating mass will be composed of weights as follows:

The piston.
Piston rings.
Wristpin and fastenings.
Reciprocating part of connecting rod.

In practice, the sum of these weights is as variable as between the respective designs of motors, and in motors in general, increasing as follows:

(A) with bore, and
(B) stroke.

Inertia increases as the square of the crankshaft speed, in revolutions per unit of time. The value of $\frac{F}{a}$ will be a maximum at o degrees of the crank, which is taken to be the top and bottom dead centers, and since inertia is induced by changing the motion of mass, as when the reciprocating parts are stopped and started, as they must be in the region of the dead centers, it follows that the tendency will be to react on the section of the cranksbaft, rather than to introduce serious complications by way of undue friction, growing out of side pressure, of the piston against the cylinder walls, which will result in uneven wear of the cylinder bore.

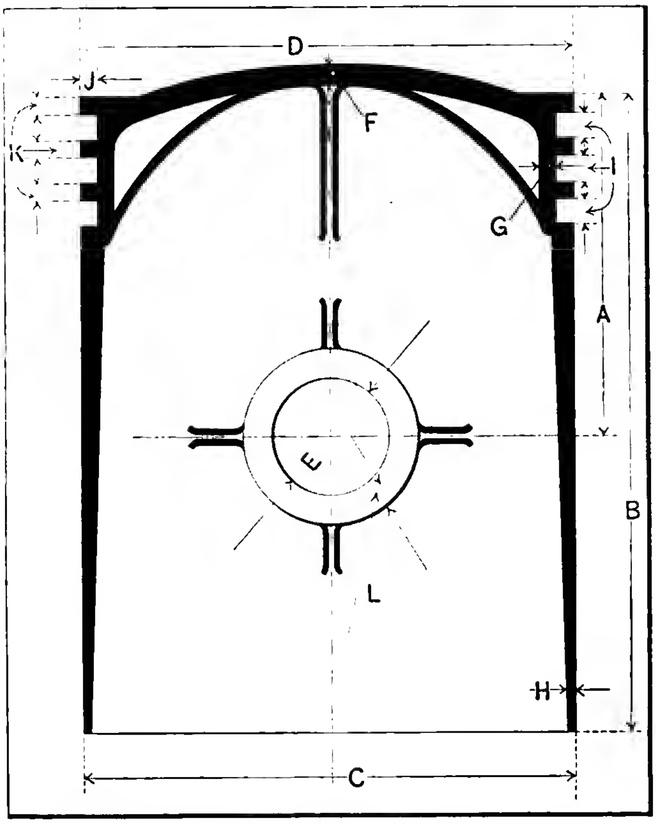


Fig. 28—Diagrammatic piston, serviceable in conjunction with the table of proportions of pistons

Referring to Fig. 28, and to the table for piston proportions, the prime dimensions, allowable in practice, will be noted. It is not believed that these dimensions are absolute, nor can it be claimed that they are likely to result in the lightest pistons possible to use, but it is the aim, in the table, to approximate averages, within the zone of good practice.

APPROXIMATE DIMENSIONS OF PISTONS

Bore of cylinder	4	4.5	5	5.5	6
**A	3	3.375	3.75	4.125	4.5
B	6	6.75	7.5	8.25	9
C	3.995	4.4925	4.990	5.4825	5.985
D	3.990	4.485	4.980	5.475	5.970
E	1 9-16	1 13-16	2	2 1-4	2 3-8
*F	5-16	11-32	3-8	13-32	7-16
G	7-64	1-8	5-32	3-16	7-32
H	7-64	1-8	5-32	3-16	7-32
I	9-32	5-16	11-32	3-8	13-32
J	19-64	21-64	23-64	25-64	27-64
K	1-8	1-8	5-32	5-32	3-16
L	5-16	3-8	13-32	15-32	15-32

*F, as stated is maximum; if ribs are placed around the circle, of a thickness equal to that of the head, this value may be reduced somewhat.

**The distance A is a variable depending upon the amount of offset of the crankshaft. All dimensions are in inches.

The thickness of the heads are not readily determined by means of formula, for the reason that none is available such as can be recommended. In any case, the heads are usually slightly domed, which is a vast factor for strength, and ribs act as supports in compression, which is satisfactory when cast iron is used. The thickness given in the table is for unsupported flat heads, and a formula which may be used to approximate the thickness under these conditions was derived from the Ericsson formula for flat plates, by Prof. William Harkness, as follows:

Let,
T = thickness of head in inches.
D = diameter of head in inches.
P = pressure of gas in pounds per square inch.

when,

$$T = 0.00439\,D\sqrt{P}$$

Were it not for the difficulty involved in ascertaining the life of a piston in service, from the point of view of wear due to friction, it would be possible to calculate the results of friction with considerable accuracy, and by limiting the lengths of pistons, reduce the weight. Then, by having only one piston ring, the same to be tight against compression, the reduction in weight in this direction would be marked; unfortunately, it does not seem to be possible in practice to do witb only one ring, and even the pistons which are fitted with three rings are sometimes in question.

To assure long life, the retention

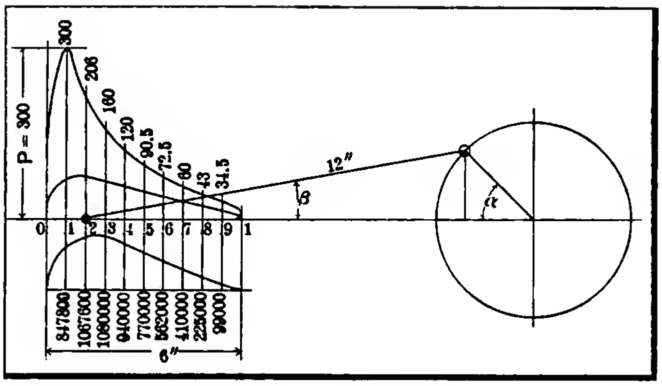

Fig. 29—Characteristic wave of pressure indicating point of maximum coming on power stroke

of compression, the pistons have to be long and the rings tight; the reason for using four rings is merely to be sure that one of them will be tight at all times. The dimensions given in the table allow for a slightly conical shape of the pistons, since the diameter at C, Fig. 28, is greater than at D. The difference is but slight, and the main reason for so finishing is to assure that pistons will not stick, as a result of unequal expansion due to heat and possible deformation.

Rings are supposed to bare on their top and bottom edges, and since the distance *J* is greater than the thickness of the rings, they will not be tight against the wall. The rings, since they must expand in the slots, working in and out, as the occasion requires, hence they must be a bearing fit, or they will stick, and fail to expand in answer to the inequalities. The right fit of the piston rings, under the circumstances, is that which will enable the fitter to move them freely when they are in place.

Cylinders Are Likely to Be Slightly Conical—No matter how well the work is done, cylinders are likely to be slightly conical, which is due to deformation of the boring bar, as it reaches into the bore, in the absence of a back bearing for the bar, and too, expansion, due to heat, and internal strains will be present to some extent, as a rule. Under the circumstances, while the cylinder is supposed to be true in the bore, it departs from this condition enough to demand that the rings in the piston be perfectly free to respond to the different diameters to be encountered throughout the stroke.

Thin pistons may deform slightly, and since there is no way of determining as to the extent of this deformation, all that can be done is to allow sufficient clearance to assure free action, which clearance should be closely held, for, in operation, if the clearance is excessive, the pistons will slap against the walls, and make a decided noise. The maximum side pressure of the pistons against the cylinder walls should be within 40 pounds per square inch as an outside figure, and were it not for the ills of excess weight, even 20 pounds per square inch would be desirable. The higher the pressure, the greater will be the difficulty in lubricating, and that the life of the motor will shorten, from the same cause, is reasonable to assume. The point of greatest pressure, in the bore of the cylinder, will depend upon a variety of circumstances, as angle of advance of the ignition, inflammability of the charge, etc. As a general proposition the wave of pressure will be as shown in Fig. 29, and maximum pressure will occur at about 1-4 of the power stroke. On the compression stroke, the maximum pressure will come when the crank is at 45 degrees, and since this will bring the piston at the same point it follows that maximum pressure, wear, and compression will tend to reduce the bore in about the same position. Fig. 30 is a characteristic diagram of piston pressure and illustrates the variations in the wave of pressure during the four cycles. This same curve shows how the maximum pressure during each cycle falls so nearly at the same point in the bore of the cylinder that it is necessary to limit the maximum pressure to that which will not squeeze the oil out from between the surfaces and allow them to run dry.

Offsetting the Crankshaft Helps to Relieve Pressure—In order to reduce wear of the cylinder wall, the crankshaft is offset sufficiently to equalize the thrust. Since the thrust to one side is greater on the down (power) stroke, by the simple expedient of offsetting the crankshaft, the excess of thrust may be delivered to the side of least thrust, hence the equalization. With a very short connecting rod, the offset should be a maximum, and in fine, increasing the length of the connecting rod, reduces the necessity for offsetting the crankshaft. Offsetting seems to be required when the length of the connecting rod is less than double the length of the stroke, and when the length of the connecting rod is three times that of the stroke, there is no advantage at all in resorting to this practice.

Wristpin Will Feel the Effect of Inertia—Since the piston is related to the connecting rod through the wristpin, the weight of the piston will induce inertia effects on the section of the wristpin, in magnitude, relatively feeble as compared with the stresses which will be set up in the section of the crankshaft. In a general way, since the weight of pistons represents about 50 per cent. of the total effective weight, from the inertia point of view, it follows that the sectional area of the wristpin should be at least 50 per cent. of the sectional area of the crankpin, when the section of the crankpin is adequate to sustain without undue fiber strain at the maximum speed at which the crankshaft is likely to rotate. It will be a simple problem to calculate the section of the wristpin in view of inertia, when the weight of the piston is known in any given case, just as the whole inertia is taken into account when it is desired to investigate the merits of a given crankshaft in view of inertia considering maximum speed as when a motor is relieved of its load.

Wristpins Are Difficult to Hold in Place—Since the ends of wristpins are in close proximity to the cylinder walls, should a pin float, even a little, it will score the cylinder wall, and then the compressed mixture will leak by, thus destroying the good relation of the same, and lowering the power of the motor. Fig. 31 depicts four methods of holding wristpins in place, and A shows the most defective one. The pin is tapered at one end, and the resultant of the pressure tends to press the pin towards the cylinder wall, while the set screw resists the effort; should the set screw back away, which is within the possibilities, the pin will back away from the taper and do much damage. B, of

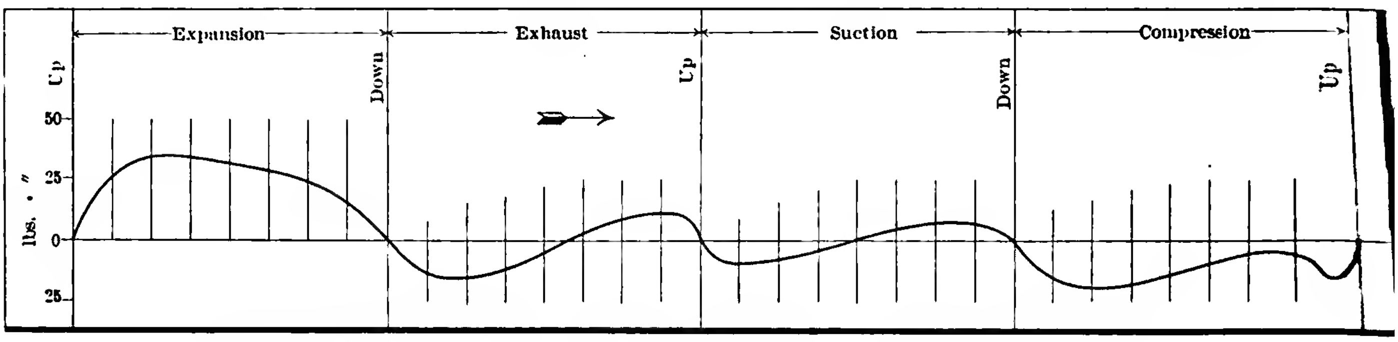

Fig. 30—Characteristic diagram of pressure on pistons during four cycles, indicating variations

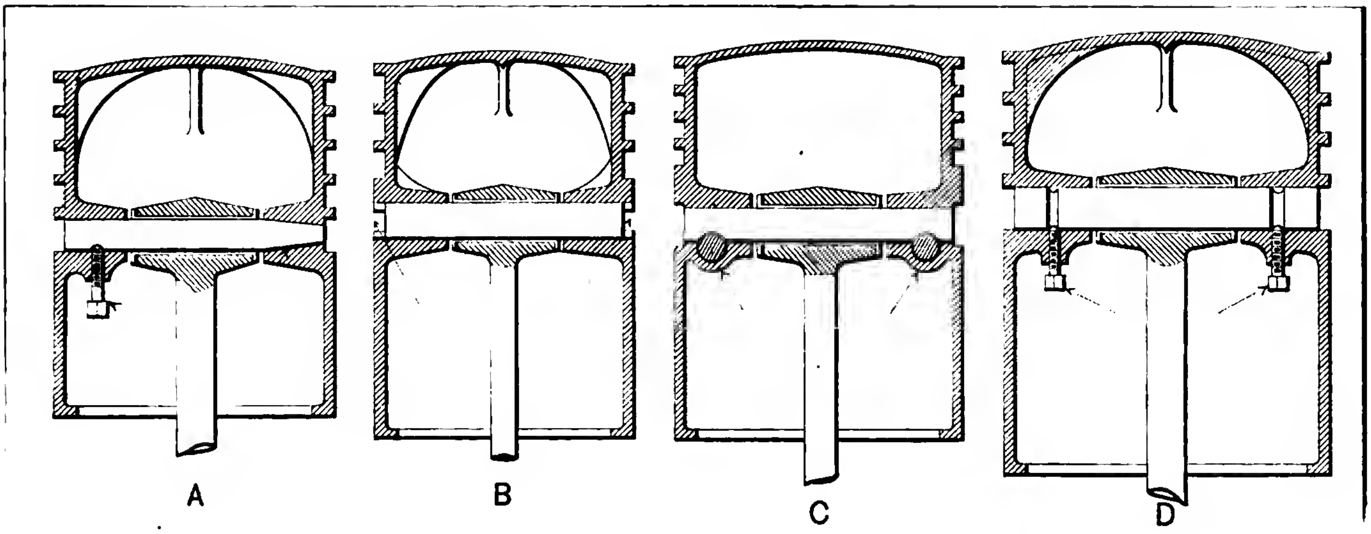

Fig. 31—Illustrating methods of fastening wristpins to prevent them from floating out

the same figure, is of a plan which works very well, in that a piston ring encircles the piston over the wristpin holes, and the pin cannot migrate out because the ring is in the way. C represents another security method of great competence, in which two bolts are passed through the boss, cutting the wristpin, and preventing it from turning, or floating out. D is a scheme involving the use of set screws, and grooves in the wristpin in which the ends of the set screws enter, and the pin will stay in place just so long as the set screws remain in the relation as shown; even one of the screws will suffice for the purpose.

Fig. 32 represents another series of methods of holding wristpins in place, and A of this series is probably the most secure method, involving the use of but one set screw, which passes through the boss and into a socket in the wristpin; the set screw is prevented from backing out by means of a cotter pin, which in turn is prevented from backing out. B represents a scheme, of recent origin, used in a well-known German product, and the disadvantage is by way of excess weight of the piston, owing to the amount of metal allowed for the taper pins to pass through. C shows a case in which the wristpin is fastened to the connecting rod, and the bearings are in the piston. A tapered pin is placed to prevent the wristpin from backing out, or turning in the connecting rod. D is of a two diameter wristpin, which is superior to a tapered end, since the fits are parallel, and the pin is free from the tendency to drift out.

Wristpins should be as light as possible consistent with strength, taking into account the nature of the stresses, which are mostly in shear. The diameter is fixed in view of bearing pressure, rather than to afford strength in shear, and it is a natural sequence that a hole will be permissible through the pin. It is never a risk to make the hole equal to half the diameter of the pin, and by calculating for shear, it is generally possible to enlarge upon this measure of the diameter of the hole.

As a rule wristpins are made of alloy steel in order to be able to make them very light, and to afford an extremely hard surface to withstand the high and variable pressure. Kinetic ability, in view of the shock nature of the load, is also one of the requirements, and on this account the older practice of employing tool steel is being eliminated. Even when alloy steel of accentuated kinetic ability is used, it is desirable to heat-treat the same with a view to affording the greatest possible measure of kinetic ability, without diminishing the surface hardness or the strength to adequately resist shear.

The wrist-pin bearing, or bushing, is sometimes made of case-hardened steel tubing, ground to size, allowing sufficient clearance to accommodate a double film of oil, which will approximate 0.006 inch. In other cases the bushings are of phosphor-bronze, with very thin walls (3-32 inch), the idea being to afford the good qualities of this material, and to abort deformation by having the walls as thin as possible. A certain amount of end play is allowed for the connecting rod, which is necessary in view of the end play of the crankshaft.

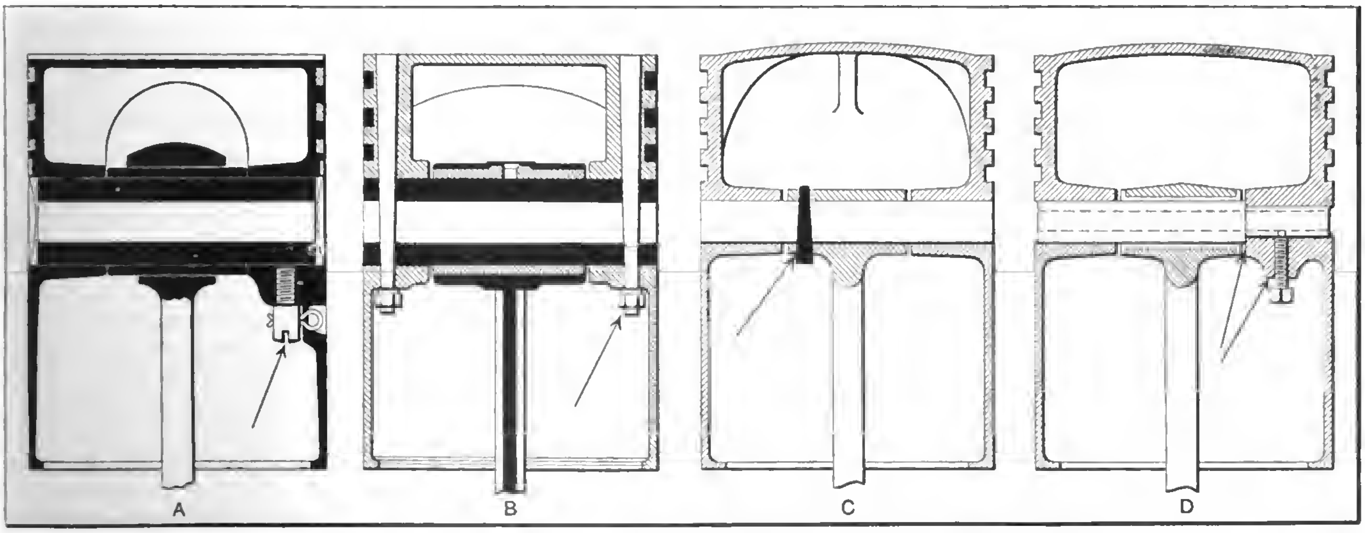

Fig. 32—Indicating additional methods of securing wristpins to prevent them from drifting

REQUIREMENTS OF THE PHYSICIAN'S IDEAL CAR

By A. D. HARD, M. D.

AUTOS specialized for particular work are becoming available for various uses. The police patrol wagon, the fire automobile, the hospital ambulance and the auto-hearse are now in use, and we hear of the traveling salesman's auto and the physician's motor vehicle. It is of the last named that I wish to speak, as I have been investigating along this line for the past eleven years. The first motor vehicle used by me for taking me as a physician to my country calls was a steam "Mobile," made at Tarrytown, N. Y. It was the fifty-second machine put out by that maker, and was undeveloped in a great many ways. It would get out of order on the slightest provocation, and was about as near being just what a physician does NOT want for service as one can imagine. But many of the faults of that primitive machine are still in evidence in the automobiles which are offered as very suitable for physicians' use to-day.

The physician who does practise in the country of the Western States requires definite factors of a special nature in the motor vehicle which is called upon to do him service. A request to come at once to relieve human distress, or to attend at a birth, or to attend the victim of some accident requires that the physician shall be taken with absolute certainty with speed and peace of mind to the scene of his work. There must not be troubles on the road to jeopardize the patient's life nor disturb the physician's cool, deliberative frame of mind which may be so very essential.

For generations past the scrub team and old buggy have been doing this work until a standard of certainty has been established below which the automobile must not fall if it is to supplant these almost relics of by-gone days.

In order that the automobile shall be specialized for the country physician's use, it must be developed along the lines which provide against uncertain service. This is of far more importance than that it shall make unusual speed. The most common uncertainties connected with ordinary automobile use on country roads, where service and not pleasure is the main requirement, consist of pneumatic tire failure, lack of road clearance, involving unusual care in running, and lack of car ability in getting out of soft roadway spots where the drive wheels lack traction and gradually bury themselves until they are not only powerless, but are very difficult to get out by outside help. These three factors tend toward distrust of the automobile for physicians' use. They must be eliminated before the automobile can be a perfect service machine practical for physicians' everyday use.

I have tried to solve these three problems, with a reasonable degree of success, but there is not at present any market supply for the demands of the physician who desires the advantages which I describe. In order to render pneumatic tires as nearly proof against uncertain service as solid tires, I have placed inside my tire casing an inner shoe composed of several layers of canvas fabric imbedded in rubber, and covered the outside of the casing with a steel rivet-studded chrome leather protector, of which the Brickstin cover and several others are found on the market. This renders my tire almost proof against road injuries, and, while it decreases somewhat the resiliency of the tire, it still is far better than a solid rubber tire for use. I get better traction, less skidding, freedom from punctures, wear resistance and pneumatic softness. This gives me the most dependable tire that I have ever had. In order to get proper speed reduction from motor to driving axle—a reduction which will afford speed enough of the motor to get good service, and yet not too much speed for the driving wheels, and at the same time get proper clearance under the car to avoid the worry of using great care in running—I consider shaft drive to a jack shaft and double chain drive to rear wheels as the very best for our country roads. There are such cars on the market, and they are very desirable where boulders and section mile stones project from six to twelve inches amid grass and weeds in the center of the road at frequent intervals.

In order to render my progress certain and independent of outside help in case of stalling, I have devised a small iron windlass, arranged with an anchor that can be crowded into the ground with the foot, by means of which I can wind up a small wire rope and drag the car with great force, though slow speed, out of any ordinary mudhole or deep obstructing rut. With this device I can get through many places in thirty minutes which otherwise would require hours of trouble and delay, and I do not have to humbly implore some farmer to hitch up his team and pull me out.

If the time comes when we can have four-wheel drive to our cars the physician should buy such a car. The maximum speed needed for a physician's use need not exceed thirty miles per hour. This would give a better delivery of traction power than to throttle down a high ratio. The weight of a doctor's car need not be as great as is common with present roadsters. There are many little unnecessary things in the common car that add weight and can be avoided. In my present car I have found sixteen bolts which might be left out entirely by slight variations, permitting one bolt to do double service. There are many parts that are not carefully thought out so as to get proper strength with minimum weight. There are several parts which do not add to the actual effectiveness, but add considerable to the weight which must be carried around to the great disadvantage of the tires, the power consumption and the handling of the car in general. Thousands of physicians are waiting for the automobile that will give proper service in their work, and until the troubles which I have indicated are obviated they will not dare to give up the horse-drawn rig that has stood the test of time.

PRODUCTS OF DISTILLATION OF PETROLEUM

In testing gasoline, as it is used in automobile motor work for fuel, since it will be necessary to distill off the fractions, they can be divided in the manner as follows:

Temperatures	Name	Percentage	Density
45	rigolene	trace	0.590 min.
45-60	chymogene	trace	0.625 max.
60-70	gasoline	1.5	0.657 "
70-120	naphtha C	10	0.700 "
120-175	naphtha B and A	5	0.737 "
175-250	kerosene	50	0.820 "

Decane, which has a density of 0.738, should be about the limit, as an outside figure, in automobile gasoline, rigolene should approximate butane, the density of which is 0.600, chymogene approximates pentane, the density of which is 0.626. Gasoline ranges around hexane, the density of which is 0.674, heptane stands between gasoline and benzine, the density of heptane being 0.688; benzine belongs in the class with octane, the density of which is 0.719.

ADVANTAGE OF THE GRINDING OF CYLINDERS

In the machining process, if cylinders are to be ground, it is unnecessary to do the machining work with great accuracy, and the effect of rapid tooling is of no consequence, since the bore will be rendered true in the final grinding process. Grinding results in a true bore, because the work is not done at such a rapid rate as to cause the cylinder to warp, and the grinder will cut the hard spots as well as it will the soft; this is not so true when the bore is finished by tooling, because the tool cannot be rigidly held, and it will back off (a little) when it butts into a hard spot. It may not be generally well understood, but cast iron may be very hard in spots, due to "chill" which brings on a mottling of white iron, in zones, or over the whole surface of the gray iron casting. Chill is not a sign of the best castings for the purpose, but it is bound to be present sufficiently to make grinding an advantage. In grinding, modern machines are designed for the especial purpose.

LETTERS INTERESTING AND INSTRUCTIVE

FRONT BRAKE DISADVANTAGE

Editor THE AUTOMOBILE:

[1,957]—Will you please inform me through "Letters Interesting and Instructive" what are the drawbacks in having the brakes on the front wheels as per your article in the June 24 issue, stating that they were being tried out in England. A. E. B.

Watch Hill, R. I.

The principal reason why front brakes are not more generally adopted is because of the complications attendant upon their use. This will be apparent to you if you consider that the brakes must be so rigged up as to operate at whatever angle the wheels set; that is, the brakes themselves and their operating mechanism must rotate, or at least turn with the front wheels when they turn. This really is the only reason of weight which can be cited against their use. On the other hand, superior braking effort, prevention of skidding and other reasons are claimed for them.

Since their first trial on the other side several very large and important firms have taken them up, and no less than four or five English cars may be purchased in the open market so equipped. If they are successful in England, why not here?

MAGNETO NOW UNIVERSAL

Editor THE AUTOMOBILE:

[1,958]—I have a small bet with a friend which I would like to have answered through "Letters Interesting and Instructive."

The bet is that 75 per cent. of the standard makes of automobiles listing from $1,500 up in the 1909 models have a magneto as a part of the regular equipment and without extra charge from the list price. C. B. CONRAD.

Richfield Springs, N. Y.

In the February 4 issue of THE AUTOMOBILE you will find a very complete list of the cars for 1909. Taking this list as a basis, it is found that there are 264 cars above $1,500 in price, and that of these just thirteen do *not* fit a magneto as a regular equipment, or at least without an extra charge. This is but 4.9 per cent. of the total number, or, to put it as you did in your letter, 95.1 per cent. of the cars above $1,500 in price fit a magneto regularly. Of those which do not there are four Elmores in the list, and these cars are equipped with a Spark Generator, which is the practical equivalent of a magneto. To give some idea of the cars which do not fit a magneto as per the list spoken of above, it might be stated that seven are two-cycle, four air-cooled, and the other two friction-driven.

CARBURETER TROUBLE

Editor THE AUTOMOBILE:

1,959]—I have made it a practice to cut out any article which I read in your paper and paste it in a little scrap book, that is, if I think it is an article which will come in handy at some future time. I have been greatly helped on more than one occasion by these articles, but of course instructions for any particular work are not always clear when an adjustment on an article of an entirely different make or manufacturer is under consideration.

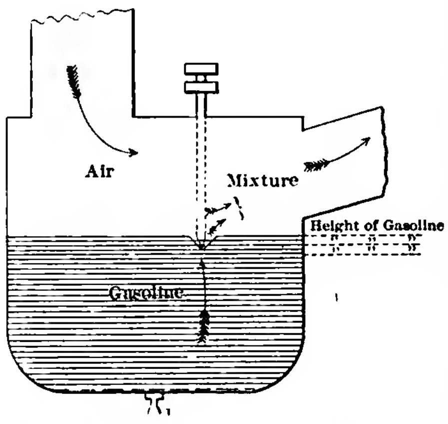
I am having trouble with my Holley carbureter after it has given me good satisfaction for two years (1907 make). After having gone all over my engine, I was fully convinced that the knock and sluggishness must be in my carbureter. I took the float out and found the shellac had disappeared from many parts of the cork float which permitted it to absorb the gasoline, making the float heavy and slow of action.

After scraping and reshellacking the float, I cannot seem to get the height of the gasoline at exactly the proper place to give me the old-time power and satisfaction.

The gasoline is forced upward through a counter-sunk hole in the bottom of the air chamber. The question is, with the car not running, how high is the gasoline to be in this countersunk hole; at the very bottom, halfway up, or flush with the bottom of air chamber? If you can enlighten me on this subject, I should be greatly obliged. No. 1,169 does not give me the desired information. F. H. THOMPSON.

New York City.

Your trouble apparently lies in the float which got soaked with gasoline and was never dried out, so that even if it were



Carbureter Has V-Shaped Fuel Inlet

scraped and re-shellacked the float was still heavy and consequently sluggish from the gasoline within. The best way to fix it will be to throw the old float away and put in another, which can be given an extra coat of shellac to avoid future trouble of the same sort.

In so far as your last question is concerned, the float should give the same level, whether the car is running or not, its function being to admit the fluid to the chamber as fast as the engine uses it up. This level should be the top of the small countersink of which you speak. The reason for this is that there should be an appreciable amount of gasoline in the bottom of the air passage for the air to draw on in starting up the motor. If there is no puddle of fuel there, in this type of carbureter it will be necessary to turn the motor over about a dozen times before enough fuel is drawn to start it.

With the gasoline level at the bottom of the countersink this would be the case, and with the level but half way up the matter will not be much improved, so the top is the proper level, and the float adjustment should be such as to attain this level.

SLIDING GEAR OR PROGRESSIVE?

Editor THE AUTOMOBILE:

[1,960]—Will you kindly tell me through "Letters Interesting and Instructive" the advantages of a four-speed selective transmission over a three-speed progressive, such as the Stevens-Duryea, for a six-cylinder car weighing 3,800 pounds and having 55 horsepower. REX C. EATON.

Estes Park, Col.

Over the selective type of gear, the progressive form has these advantages: a single shifting lever, shifting in a single direction; that is, being way forward, a continuous backward pull will give in order every successive speed; since it is necessary to shift into low to start, and then pick up the various speeds as the car gains headway, the lever continues to move in the one direction with no chance for a mistake.

On the other hand, the advocates of the sliding gearset with selective changing claim that the progressive gear box is very long, and consequently very heavy; that in stopping it is necessary to remember always to shift backward through all speeds to low, so that when starting again the gears are in the low position; that more gear changing is necessary with the progressive form than with the selective, and that for this and other reasons novices damage more gears.

Principal among the advocates of the progressive gear in this country are Packard, Stevens-Duryea, Royal, Franklin (1), Middleby, Studebaker (1), Sultan, Gaeth and Acme (1). Among the French constructors these prefer the progressive form: Renault, C. G. V. (all but 2), Panhard, etc.

As for the three-speed and four-speed proposition, that is an entirely separate matter, since both forms of transmission may be constructed with two, three, four or more speeds. The argument for a large number of speeds, regardless of the form of transmission, is this: The greater the speed range of the engine—that is, the greater the difference between the slowest and highest speeds possible—the greater the necessity for many changes, since without them the large range is divided over but few intervals, which means that the engine must run very slow at the bottom of each interval and very high near the top of each interval to maintain a constantly accelerating rate of speed, or the reverse when slowing down. By dividing the interval into a larger number of steps the action of the engine in covering each step and overlapping into the next higher or lower is more constant.

Introducing the six-cylinder engine changes the problem very materially. Without going into that here and now, it may be said that the more flexible the engine the less the necessity for a transmission, as witness the very flexible steamers made without one. So, with the most flexible gasoline engine it seems reasonable to think that a lesser number of speed changes would be needed, rather than more. From this viewpoint it would seem as if the proper transmission for a "six" would be a three-speed.

CONDEMNS STILZ ENGINE

Editor THE AUTOMOBILE:

[1,961]—If the notice of the Stilz engine and the enthusiastic editorial thereon in your issue of July 8 is cunningly contrived to arouse controversy, then it is well timed; for, at the present time there is no more interesting subject in the sphere of the automobile all over the world than the engine. From reports received it is evident that the Old World is exercising its mind strenuously on this subject.

The reason for this is evident, the rest of the automobile being a matter of mechanics only while the engine involves physics, deep and hard to understand; at any rate, rendering the attainment of perfection extremely difficult.

Your editorial is an indication of this, for, while showing the interest, yet it is likely to lead inventors and investors astray. My criticism is based upon your suggestion that there may be value in the Brayton or "Constant Pressure" type of engine, this type having an air, or mixture, pump, a passage or reservoir for conveying or holding the working fluid, and a working cylinder; the working fluid being maintained at a constant pressure from the time it leaves the air pump until the supply to the working cylinder is cut off.

The rotation of the engine is produced by the differential action of the pump and working cylinders, that is to say, that it is necessary that the working cylinder be larger than the pump, otherwise the engine will not operate. Hence the work done can only be in proportion to the difference of displacement of these cylinders.

The pump is negative, and the working cylinder positive, but only usefully so by the difference of displacement. This means that the mechanical efficiency of the combination must be low, even if we consider only the losses by fluid friction, neglecting the friction losses of the many moving parts of large size, such as pistons.

From the above it is seen that, no matter at what pressure the engine is operated, it is bound to be much heavier than one in which the pumping and power producing operations are both carried out by one simple mechanism, such as the trunk piston in the ordinary four or two-cycle engine.

As to thermal efficiency. The loss of heat in the cooling of the pumped air or charge, as described, is so much lost work. This is easily seen when one considers that supposing the pumped air were not cooled, then its pressure would be so much higher and less work would have to be done to attain the same result. The recovery of heat from the exhaust gas heater mentioned in the article is of no value to the thermal efficiency of the engine, for the heat loss I refer to has gone to the atmosphere, and cannot be recovered.

By far the greater heat loss, and that which renders this type of engine so extremely inefficient, is that to the working cylinder walls, this loss becoming greater as the size of the cylinder is reduced.

The theoretic thermal efficiency of a Brayton engine, neglecting all heat losses is 30 per cent.

The actual thermal efficiency so far obtained is not more than 8 per cent.

The ordinary four-cycle stationary engine can be relied on to give 25 per cent.

The average automobile engine shows 15 to 18 per cent.

The Diesel engine has actually shown 45 per cent.

It seems waste of time to work on a system so defective, although the allurement of the analogy "like a steam engine" is very enticing so long as one does not consider the cost in weight of engine and volume of fuel per horse power, which actually render such an engine useless for the purpose.

HUGO C. GIBSON.

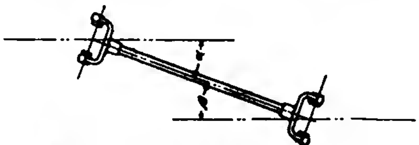
New York City.

Mr. Gibson pays us a great compliment in his opening inference that the article relative to the engine in question was only published to start a controversy, which of course was not the case. The closing sentence of his letter, in which he says: "* * on a system so defective," seems to stand without proof unless he imagined that the previous statements of the results obtained from a Brayton engine in 1873 can be considered as positive proof. Since this statement is directed against a type and not against any individual form or shape which experimenters have seen fit to give it, it is not fair to judge the type as a whole by the worst example. The inference, too, in the statement, "Not consider the cost in weight of engine and volume of fuel per horsepower," is that the form under discussion is both heavy and wasteful of fuel, neither one of which have been proven, so that they must be regarded as Gibson estimates.

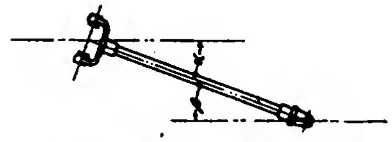
CLEARS UP UNIVERSAL JOINTS

Editor THE AUTOMOBILE:

[1,962]—Referring to your answer to No. 1,915, in the June 17 issue of "The Automobile," I am inclined to take the same view of your answer as Mr. Vanderbeek in his letter (No. 1,930) in your July 1 issue.



When $\alpha = \beta$ each __corrects__ the variation in angular velocity of the other.



When $\alpha = \beta$ each __adds__ its variation to that of the other, thus doubling it.

Sketch of Joints in Inclined Plane

Possibly another sketch, considering the middle section only, would make the matter more clear to the non-technical reader. I am adding this suggestion to what has already been said, for the reason that I consider the point a very important one, and one with which all manufacturers, garages, or others who are liable to have to do with the assembling of propeller shafts, should be familiar.

SPICER UNIVERSAL JOINT MFG. CO.
Plainfield, N. J. C. W. SPICER.

MORE ABOUT BUICK TROUBLE

Editor THE AUTOMOBILE:

[1,963]—In answer to No. 1,926, I would suggest that Don S. Numbers remove the left wheel and, by hammering the washers on the studs which hold the expanding band, restrict the side play of the brake band. It is also advisable to clean off the brake facing with gasoline and make sure that the brake spring is not only sound, but tight enough; as a weak spring will sometimes cause the rattle he mentions.

MURRY FAHNESTOCK.

Allegheny, Pa.

This gives another view of the trouble experienced by a Western correspondent with a Buick Model 10. Thus far, the three remedies suggested by those who have suffered in the same way have been: Bolts so long as to strike brake mechanism; loose emergency brake bands; and now, brake band holding washers and weak brake springs. Surely with these numerous helpful suggestions at hand, no owner of one of these cars should ever need towing home.

HAS NUMEROUS TROUBLES

Editor THE AUTOMOBILE:

[1,964]—Will you kindly advise me the cause and remedy for a knock in my engine which occurs only when running on partly open throttle. My automobile is a two-cylinder opposed 22 horsepower. This knock seems to occur when I shut off throttle (as in going over a rough place in road or around a corner), and open it quickly. Engine seems to respond quickly to throttle when standing still, but not when running as mentioned above.

My engine has just been cleaned, and is a new one, having been used only three months. Could the cause be faulty carbureter adjustment? I have a Schebler carbureter, Model D. Please explain how to adjust properly, the air valve to carbureter. How can you tell when you have too much air or not enough?

I also have a Remy magneto Type L on my car, and I find I have to run on my batteries almost all the time unless engine is speeded up; then magneto works all right, but when running idle, engine will die unless switched on to batteries. I have only had my magneto about two months; bought it from a garage for a new magneto. Is it likely I was sold a second-hand one—one that has lost its power, or is it faulty adjustment?

ROY N. CHELF.

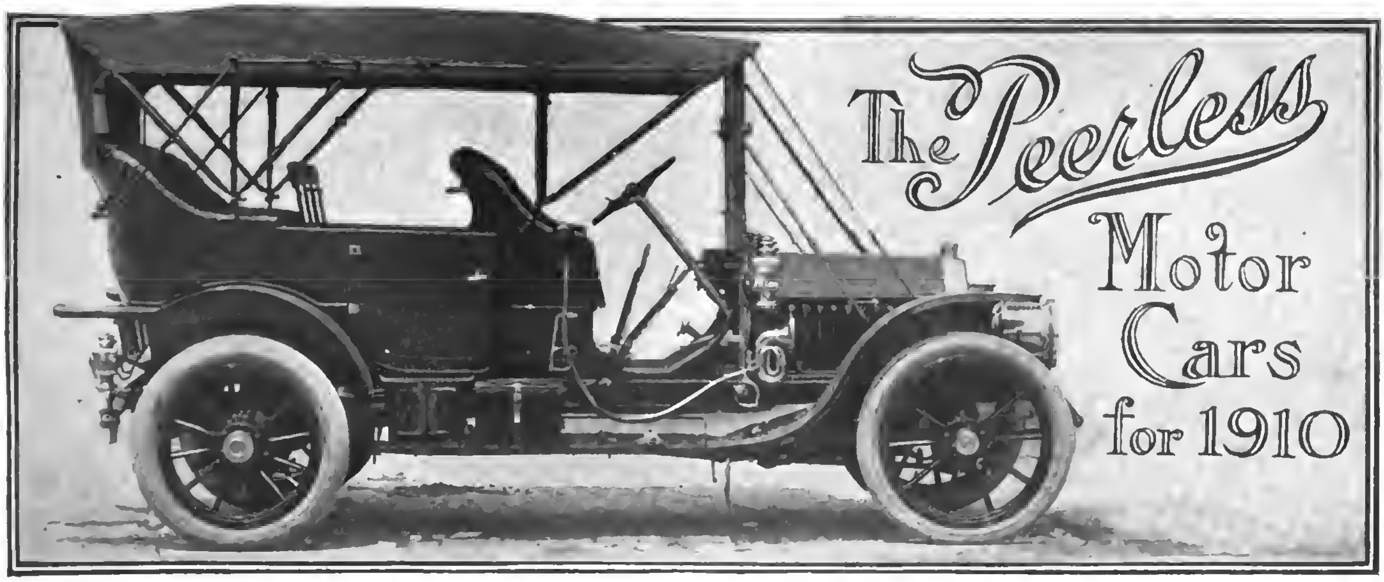
Brooksville, Fla.

From the way in which you describe your trouble it would appear as if there was too much play in the connecting rod bearings, which can only be fixed by taking the entire engine down, scraping the bearings and tightening the connecting rod caps, which should be done so as to decrease the amount of clearance between the pin and the bearing. It is barely possible that this can be accomplished by simply pulling the connecting rod bolts up tighter.

On the Schebler carbureter the air valve stands vertically, with the adjustment at the bottom. There is an adjusting nut and a locking nut. To adjust, run your engine as rapidly as is possible, with the throttle wide open, and vary the auxiliary air adjustment, noticing as you do so whether the engine runs better—that is, faster, or not. In doing this you will soon notice an approximate point at which the motor will act best; then, confining your efforts to this point, determining it as closely as possible. It is doubtful if you will get this exactly right the first time you try to adjust, but by getting it very closely and then running the car with it that way you can readily determine whether the engine needs more or less air.

Your magneto trouble sounds like faulty adjustment, and it would be well for you to seek advice from the manufacturer. This is a good make of magneto, and when properly adjusted it should ignite the motor charges in a proper manner—not for a short time, as you state, but continuously and regularly. Moreover, other things being equal, it should work better, rather than more poorly, at high speeds. If the garage sold you an old magneto, representing it to be a new one, you should be able to get redress in a legal manner and in such amount as would reimburse you for expense incurred with it, even to the extent of payment for sending it to the factory to have it examined and made right.

It is just possible that part of the knock which you experience is due to opening and closing the throttle too quickly, as this always makes an old engine knock.



As Model 27 Peerless Four-Cylinder Touring Car Appears in Its Latest Form

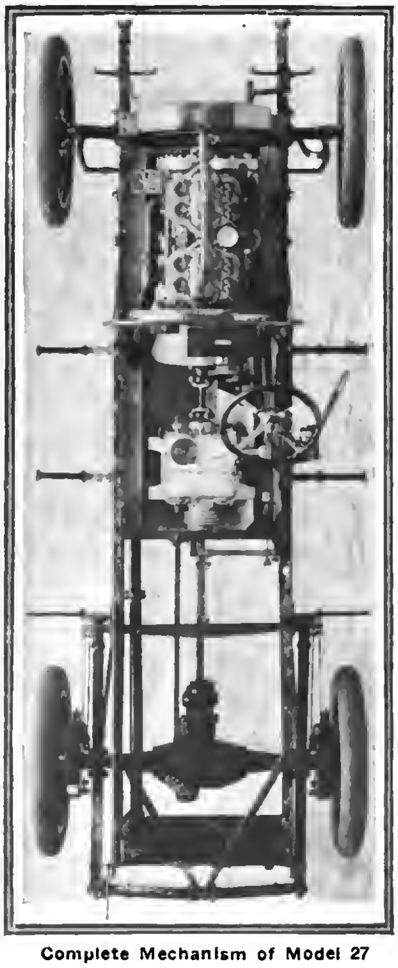
ALL that the name implies, is a catchy phrase which applies with peculiar force to the product of the Peerless Motor Car Company, of Cleveland, O., since the makers try in all of the shop methods, purchases of material, and even in the sale of finished cars, to attain the very highest, or peerless, grade. That this has been successful is now beyond question and the product of this concern's shop, shown complete on another page as it appears to-day, is fairly granted a premier place in the list of good cars, whether foreign or domestic.

In the purchase of raw materials, not only has this country been gone over as with a fine-toothed comb, but all of Europe has been drawn upon to secure the best materials, so that every part of the car, no matter how small, will be up to the standard set for the whole, namely, without a peer.

If the result of this active campaign for the best in materials and workmanship is not reflected in the workshop appearance, it would be hard to say where it would be shown. So the view on the next page shows the present appearance of the Cleveland shop. This was not a spontaneous growth, but rather grew to its present imposing size little by little, each year seeing the necessity for another big addition, until it ultimately reached the present vast expanse. Even now, rumor has it that another addition would be welcome for the floor space it would afford.

There Are No Changes Over Last Year—As the adjacent view of the assembled chassis displays, the whole construction is the same as in previous years, no changes worthy of the name having been made. This, put in another way, means that in an extra year of hard service no additional fault developed. For the ensuing year three models will be staged, known to the trade as: Model 27, a four-cylinder car of 30 horsepower, equipped with any desired body, or even the bare chassis may be purchased: Model 28, a 50-horsepower, 6-cylinder, with a long list of body types, and the new town car, Model 29, a 20-horsepower "four," which is only turned out with limousine and landaulet bodies.

The engines of the two former are alike as to bore and stroke, this remaining unchanged at 4 7-8 inch by 5 1-2 inch, while the new little motor also inclines toward a long stroke, the dimensions being 4 by 4 5-8, which gives a ratio of 1 to 1.155 as against 1 to 1.3 for the older engines, revealing in this the modern tendency toward a longer stroke relative to the bore, said to give also much more power.



Complete Mechanism of Model 27

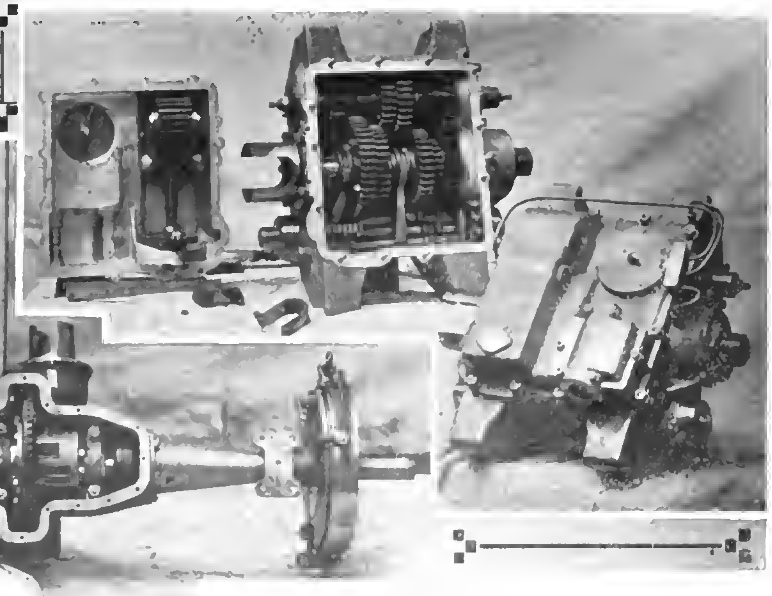
Conservative rating is in force on all models, as is evident from a brief mention of the A. L. A. M. rating for the three sizes, these being 38 for the motor actually rated at 30, 57 for the so-called 50-horsepower engine, and 25 for the little fellow, which is called a 20. All three cars are to be had with comparatively long wheelbases and rather large tires, the combination which always makes for ease and comfort of riding.

Interrelation of parts and their location, as shown on the chassis of Model 27, is the same for all models. The engine is placed in front, drives through an expanding band clutch and a readily detachable universal coupling of simple design back to a four-speed transmission located in the center of the car, right under the driver's seat and hung on a sub-frame, thence by exposed propeller shaft back to the differential mechanism and full floating rear axle, the latter retaining its distinctive feature of two universal joints incorporated in the construction to allow of sustaining the camber of the wheels and arched rear axle, which give the Peerless car such a different rear appearance.

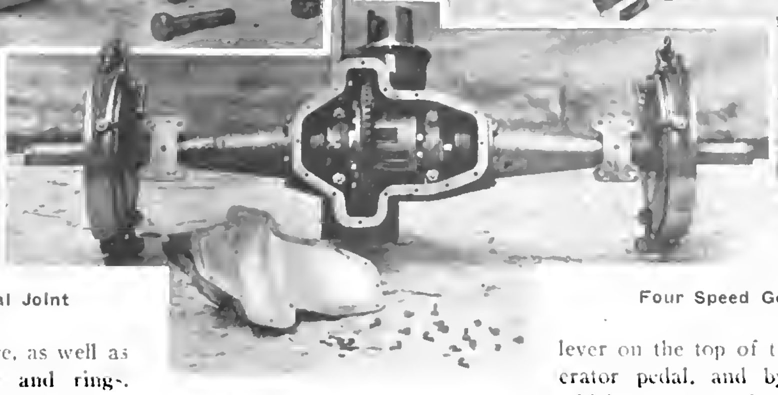
Details of the Power Plant—To chronicle the changes in the engine, or in fact, any part of the car, is to go into the infinitesimal, so that the statement made above that there are no changes, is practically true. Thus, to take up the motor parts, the crank case is as before, a one-piece casting of aluminum, but with an increased number of stiffening ribs. The rear portion of the case is made slightly larger, particularly the oil reservoir, which now has an increased capacity and the oil pump enclosed within it, making the lubrication system complete in itself.

The cylinders are cast in pairs with offset intake and exhaust valves, these being made with taper seats from a special imported alloy steel. The cylinders pass through the most careful machining process given to any part of the car, being bored, reamed, ground, and finally lapped with the pistons and rings in place, a special polishing preparation being used. This results in an almost perfect sur-

Clutch and Universal Joint



Four Speed Gear Box Shows Few Changes



Rear Axle with Cover Off

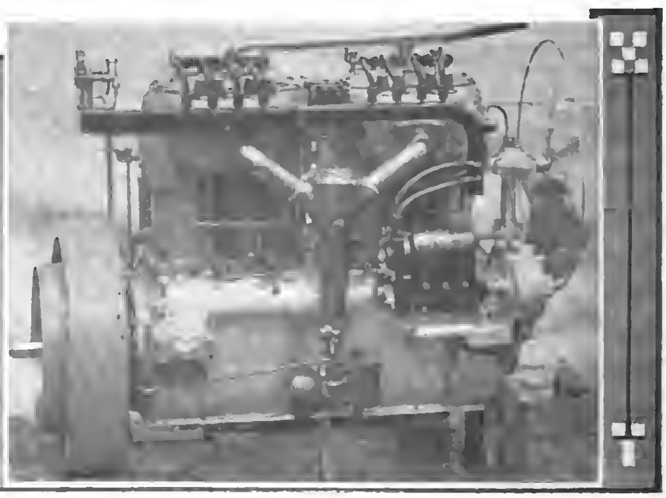
face for the cylinder bore, as well as perfectly fitting pistons and rings. Since this method insures compression tight cylinders, which means starting on the spark nearly every time, the extra work is well worth the time it takes and the money it costs. Strictly aside from the starting feature, this makes a smooth engine.

An additional precaution taken to have the engine parts right lies in the balancing operation; each part which enters into the rotating element is carefully balanced singly and then in combination with the others, in pairs, and last in groups. Finally, the whole is tested for running balance.

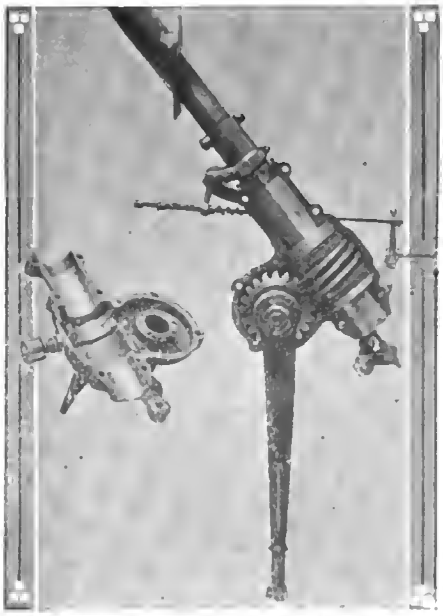
Carbureter Is Slightly Changed—On Models 27 and 28, a vaporizer of new design is used, which embodies several very important improvements. Ae the right-hand view below shows, the carbureter is really in one piece with the inlet pipe, the former being placed very low down on the right side of the motor. This low position is not accident but design, the float chamber in that position being so low that fuel is supplied to the engine under gravity feed on any grade likely to be encountered even with the gasoline tank nearly emptied. As will be seen, the form of the vaporizer is very simple, while the inlet pipe is made different from the usual run to co-act with it properly. The mixing chamber within the pipe is of larger capacity to provide a better mixture when the motor is throttled to slow speeds or working hard on hills. A single seated, vertically acting throttle is used, this being controlled by hand lever on the top of the steering wheel, by foot accelerator pedal, and by a sensitive governing device, which regulates the throttle opening to the motor speed regardless of load. The other side of the engine carries the pump drive and piping, as well as being the side upon which the oil reservoir is located. The pump is gear-driven and of the gear type, herringbone gears being used to insure absolute silence. These gears are placed in a vertical position, one above the other, the top one being driven.

Transmission Case Moved Forward—Still located in the middle of the car, the gear box has been moved slightly forward, making it possible to move the quadrant on which the change speed and brake levers operate forward to a vertical position within easy reach of the operator, and more comfortable withal. This forward position of the case allows of easy inspection, oiling or cleaning, since the case, and with it the cover, is directly below the driver's seat. Another and more weighty argument in favor of this location is that by moving the gear case farther away from the rear axle the propeller shaft is lengthened, and coincident with this, the angle which the shaft makes with the horizontal is materially reduced. The reduction in this means a nearer approach to a straight line drive.

On the ends of the propeller shaft are a pair of universal joints, one on each end. These remain unchanged, but the crosses have been fitted with roller bearings, which replace the ball bearings formerly used. The rear axle consists of but three pieces, the cast steel differential case, bolted at the ends to the



Two Sides of the Splendid Four-Cylinder Engine of Model 27 Contrasted two flanges, to which the one-piece heavy gage tubing is welded. These axle tubes are flared from the spring saddles toward the steel gear case, giving the axle as a whole much strength and an imposing appearance. The power is transmitted by means of bevel gears, both axle ends and differential ends acting through jaw clutches. On each side of the balance gear is placed a universal joint consisting of a 14-toothed gear meshing within a similar internal gear. The teeth are rounded so as to allow some lateral movement as well as vertical motion. This constitutes the mechanical device which allows of the cambered rear axle as well as the camber and dishing of the wheels. The housing containing the bevel gears is a steel casting split 2 1-4 inches above the center line, instead of exactly central as before. The castings being of greater depth, have greater strength than before and more rigidity, also. Since the case is filled with oil for lubricating purposes, this new form of construction makes the differential case more nearly oil tight.



Steering Gear Partly Dissembled

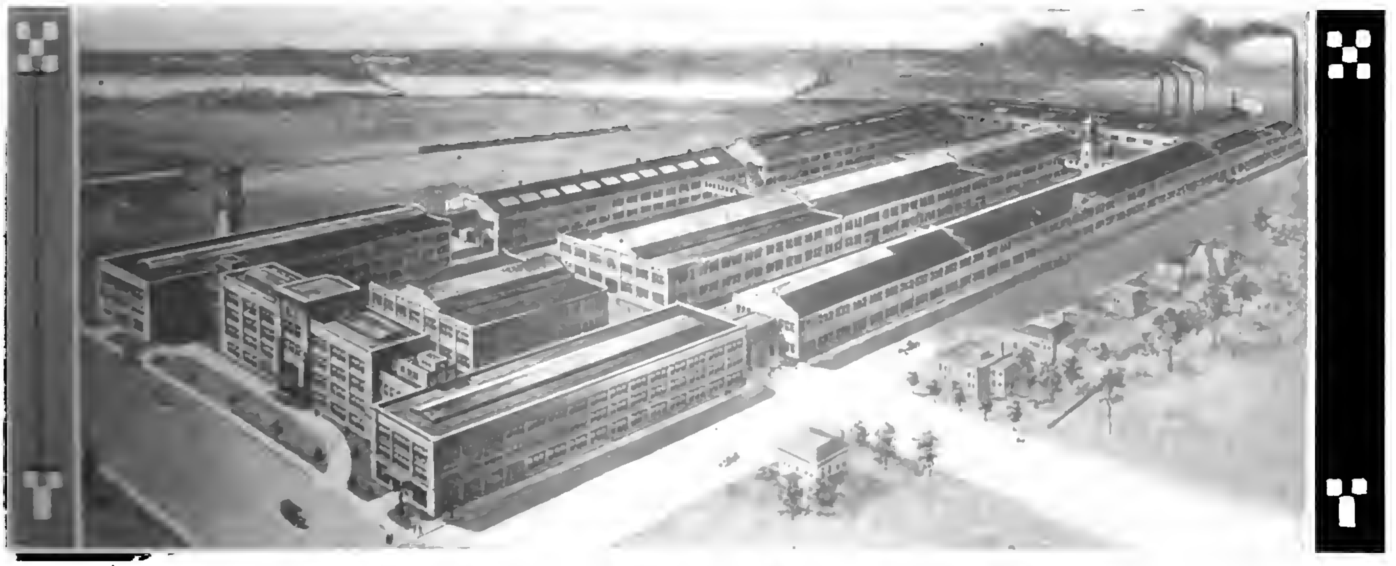
New Torque Rod an Improvement—Distance rods are attached to both frame and rear axle by means of joints of the ball and socket type, so that the car is propelled through these rods and not through the springs. A torque rod of new design takes all other possible strain off of the springs, which have nothing to do other than support the body and load. The rod is of channel section pressed steel instead of the former tube. This rod is attached to the frame at the forward end by cushion springs, which are completely enclosed in a neat tubular case.

In the front axle is seen a piece of work from the skilled mechanics on the other side of the water, this being an imported, solid, one-piece, drop forging, with the spring saddles forged integral. The section is the now generally adopted I-beam, and while the drop is not excessive, the bottom of the front axle is the lowest point on the car. Front wheels turn upon roller bearings, and the pivot point of the knuckles is supported on imported ball bearings of large size and special design. The cross rod is located behind the axle, where it is protected from road obstructions. Like the front axle, the springs which support the body and make life in it worth living, are imported from France, these bearing the trademark of Lemoine, Paris. In material they are of the very best that money will buy, this being an alloy steel, known as silico manganese, which possesses a number of physical and chemical properties, particularly fitting it for spring use. To improve the riding qualities of the car, if this be possible, the front springs have been increased in length by two inches and the rear side springs by four inches. The same flat shape is retained, as is the platform construction in the rear. In combination with this is the dropped frame, which gives a low center of gravity and large road clearance, too.

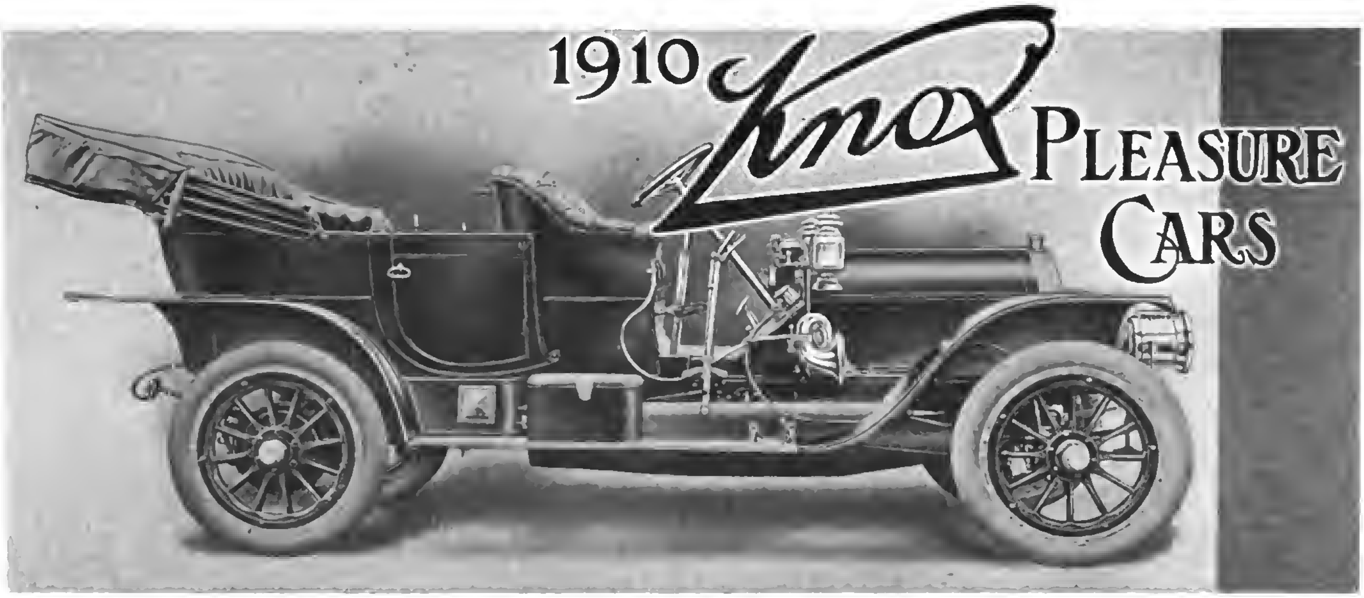
Unchanged is the term which applies to the frame also. This is still of cold rolled pressed steel, truss pattern, with the sub-frame for engine and transmission. The frame section is that of a channel, and the drop at the rear is 2 1-2 inches, while the overall length is 160 inches on Model 27, and 174 inches on Model 28. This corresponds to a wheelbase on the first of 122 inches and on the second of 136 inches.

Distinctive Peerless Body Types—Body types are unusually numerous, there being six to choose from in the case of both of the larger cars. These include the regular touring car, close-coupled body, roadster, pony tonneau, limousine and landaulet, all being built along the distinctive Peerless lines, namely, the combination of curves and straight lines, which never fails to please. The front fenders have been flattened a little and a wing added on the inside to prevent mud splashing up. This is carried back to the rear fenders, completely enclosing the under parts of the mechanism, and thus adding to the beauty of the car as a whole. Thirty-six inch wheels are continued, these being of the artillery type with dished spokes. The dished spoke is said to be the form which stands up best under side strains, while at the same time being stronger than the straight spoke form. Thirty-six by four inch tires will be used on the front wheels, which size is increased to five inch in the rear, where the work is more severe. Standard colors for the season will be: on touring cars and roadsters, maroon bodies and coach painter's red running gear; on all enclosed cars, maroon or blue. The closed cars will have upholstering of an imported cloth, known as Wulfing cloth, or, if desired, goatskin. All enclosed cars are fitted with an electric lighting outfit, consisting of a set of Fulmen, imported 60 ampere hour batteries, carried under one of the rear seats, the interior being wired for the tungsten lamps.

The prices vary with the body types, the touring body on Model 27 chassis being $4,300, and the same equipment on the six-cylinder chassis listing at $6,000. The little car has but one price, the same for both bodies, $4,500.



Bird's-Eye View of Peerless Factory As It Will Appear In a Few Months When Completed



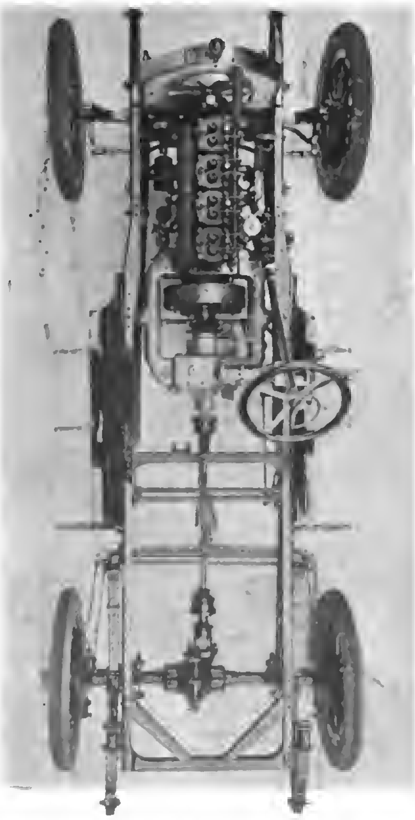
Model R, the Knox Leader for 1910, a Car Which Bristles with Good Features of a "Different" Nature

VERY recently—last week, in fact—there was described in these columns a car hailing from Massachusetts, the construction of which embodied the unit power plant, three point suspension, multiple disk clutch, and other advanced features. Strange to relate, another car which embodies these same features also comes from the Bay State, and still more strange is the fact that the two factories are within a very few miles of one another. The company whose output will be described here is the Knox Automobile Company, Springfield, Mass., a well-known concern, actively engaged in business ever since 1900.

For 1910 this concern will turn out three models, Model M, continued from 1909 and previous years on account of its continued successful career; and the different cars just added to the list, Model R, of 40 horsepower, which replaces Model O of last season, four cylinders, and a new "six," Model S, rated at 57 horsepower. All of the newcomers follow in a general way the construction of Model O, since the success of that model is taken as the best kind of proof that the form of construction is wholly right.

All Engines Are Water-Cooled—All Knox motors are now water-cooled, with valves located in the head, a location which has become very popular on the other side, being a noticeable feature of every winning car of this season. Model "R" cylinders are 5-inch bore, 4 3-4-inch stroke, rated at 38 horsepower, A. L. A. M. standard; Model "M" is 5 1-2-inch bore and 5 1-2-inch stroke, rated at 48 horsepower, A. L. A. M. Both have cylinders cast separately; each consists of two distinctive castings—the cylinder proper and the head. The water jacket of the cylinder is cast integral therewith, the water entrance being at the lowest point, and the outlet near the top on the right-hand side of the casting.

In the upper end of the cylinder casting a deep concentric groove is machined in which fits a copper asbestos gasket. Upon this is seated a corresponding concentric tongue formed on the bottom of the head which is firmly secured to the head by four bolts. It is impossible to bring these parts together except in a correct location and with a correct bearing. This joint, it should be noted, is not a water joint; in fact, there are no water joints in this construction which can occasion a leak into the cylinders.



How the Chassis Looks from Above

By this simple construction cylinders are secured symmetrical in form and perfectly uniform in cross section, which fact reduces to a minimum the liability of going out of round. Furthermore, they may be easily and accurately machined, the casting being entirely open at both top and bottom. The bottom of the head is also machined so that the entire surface of the combustion space is smooth and accurate in capacity, giving a perfect balance of the volumes of all cylinders, which contributes to sweet and even running. Machining the combustion space has other advantages, usually not taken up because of the cost.

In addition to this, the smooth surface of the combustion space is less likely to retain deposits of carbon than the rough casting, and the entire absence of sharp points, edges and roughness is supposed to be a preventive of premature ignition. The head is cast integral with its own independent water jacket, and the inlet and exhaust passages from the manifolds to the valves are cored in the head. The water spaces are large, the water circulating freely around all the parts mentioned as well as around both valve seats, the head being cast with a division through it horizontally, making two separate water spaces, the water circulation being directly over the valve seats, returning through the top water space to the return manifold, the water entering the lower one through a single U-shaped hollow casting. The "U" connection and the return water manifold are held in place by a double clamp and single bolt easy to connect and disconnect.

Flat Valves Given the Preference—After an unsatisfactory experience of two seasons with the conical seat for the valves, and after an exceedingly thorough trial of the flat seat, the latter has been adopted for use on all motors. The valves are mechanically operated by rockers and push rods on the right side of the motor. The upper ends of the push rods are in the form of hardened cup-shaped sockets and screw in the ends of the rods for adjustments of the valve openings; they are securely fastened by lock nuts and the outer ends of the rockers with which they engage are ball shaped. Oil is placed in the pockets, preventing wear at this point. This construction and the positive adjustment of the valve rods, together with the use of spiral springs for taking up lost motion in the valve mechanism, has resulted in an exceptionally quiet engine, as well as one of great flexibility.

In the three point suspension, which was worked out by Knox in 1900 and used ever since, the two points are on the yoke surrounding the transmission and clutch, while the single point is located at the front end, where the weight is carried on a flexible trunnion hung to a bronze cross member of inverted channel section bolted to the side members of the frame. There are two other cross members with flared ends forming the gusset plates, both of which are hot riveted to the frame. The complete power plant is composed of three separate units, the motor, clutch and transmission, any one of which can be easily removed without disturbing the other. The whole power plant can be taken from the chassis by the removal of four bolts, one on each side of the yoke at the rear, and the trunnion bolts in the center of the forward transverse frame member, the uncoupling of the forward universal joint, muffler pipe, ignition wires, throttle and brake connections which, under ordinary circumstances, would require about 45 minutes. A change over last year consists of casting the crankcase and yoke separately, and bolting them together, a tongue and groove making for accurate assembling.

Details of the Aluminum Crankcase—All the crankcases are similar to Model "M," cast from aluminum and composed of four pieces—the case proper, the bottom of base, and the timing gear case and cover.

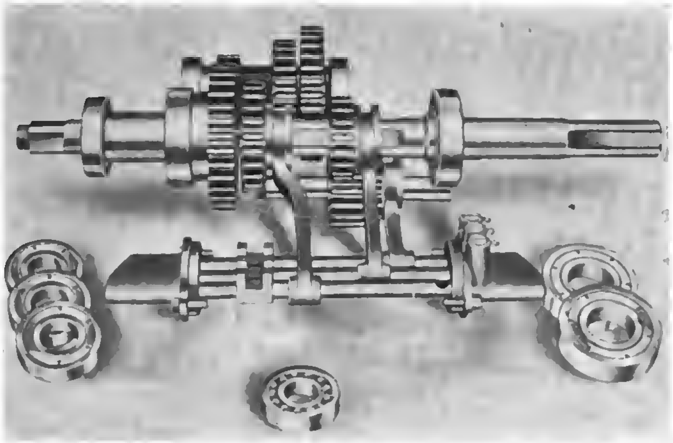
The shape is that of a rectangle, or perhaps more nearly a square, the crankcase proper forming the top and two sides, while the bottom is formed by the oil pan, which, however, is not very much on the pan order, being very flat and shallow. The bottom of the case is easily removed and acts chiefly as an oil reservoir. The aluminum in these castings is an alloy, obtained after months of testing and careful analysis, which, while sacrificing but little of the inherent lightness of aluminum, has ample strength for its purposes. The case proper has a massive extension cast on each side of the rear, which makes, when finished, one part of the forward joint for the side arms of the yoke. This casting forms the upper half of the crankcase or engine bed; the crankshaft and bearings being bolted to the lower side of it.

All crankshaft and connecting rod bearings are made of Parson's white brass, making it easy to replace worn bearings. With this metal it is impossible to injure the crankshaft in case of a hot bearing from lack of lubrication. The lower half of the crankcase can be taken off without disturbing the main bearings so that the engine could be run without it.

Connecting rods are made from drop forgings of nickel steel sufficiently heavy to stand the strains of a powerful motor. The heads are fastened with four bolts having contracting double lock nuts, a positive fastening, the four bolts making it practically impossible for the bearings to wear more on the ends than the center, which after long use would have a tendency to concave the wristpins.

A circulating pump of the centrifugal type is used on all motors, and is driven by spiral gears from the camshaft, located on the right side of the motor. A special spring connection is used, made to snap by should the pump become frozen or stopped by obstruction, thus avoiding any danger of damage to gears or shafts; the pump can also be entirely drained. The water is delivered from the pump through a tapered manifold to the lower end of each cylinder jacket, thence out of its upper end, through the outside connector, into the lower chamber of the head, then into the upper chamber and out of the right side, into the return manifold and to the top of the cellular radiator. The action of the radiator is assisted by a six-bladed fan, positively driven by a leather-covered chain belt.

Ignition on Models "M" and "R" is by Bosch high tension magneto and vibrating coil and timer—two complete systems with two sets of plugs. The magneto is located on the left side



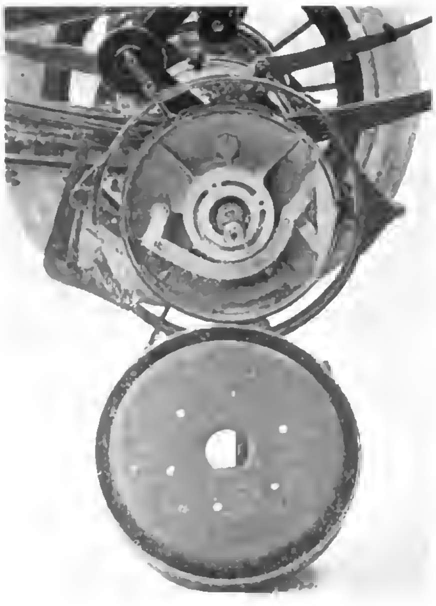
Heart of the Transmission Used in Models R and S

of the motor, and is driven from the timing-gear case. The ignition timer is driven by spiral gear from the oil pump shaft on the right side of the motor.

Great Stress Laid on Lubrication—The makers of this car say that one of the most important points necessary to the perfect working of machinery is proper and systematic lubrication at all times. The motor, being subjected to different variations in the speed and power required, makes it even more important that it be considered one of the most essential points in the perfect motor car. In all Knox motors what is known as the De Dion system is used, which has proved to be efficient, economical and satisfactory. With this system it is practically impossible to burn a bearing, the oil first being strained, and as all are lubricated from the inside, has a tendency to carry grit away from the bearings. The camshaft near the center drives a downwardly projecting shaft for the rotary gear pump, which is also fitted with a spring connection to snap should it become clogged.

The lower part of the crankcase forms an oil reservoir from which, through a strainer, lubricant is drawn by the gear-driven pump and conveyed through an oil pipe on the left side of the case, from which are pipes leading to the various bearings of the crank- and camshaft. In each connecting rod is drilled an oil passage, the opening of which registers once in every revolution with a similar opening in the crankpin, so that the wristpin is not only lubricated by the oil distributed centrifugally but by direct pressure through the connecting rod. A pressure gauge, located in the sloping footboard, registers the amount of pressure, which is varied at will by means of an adjustable by-pass located on the left side. The oil screen is easily detached by a socket wrench furnished with each car. The filler cap and petcock showing oil level are also on the left side. With this sys-

Knox Three-Plate Clutch Dissembled, Showing Cork Inserts



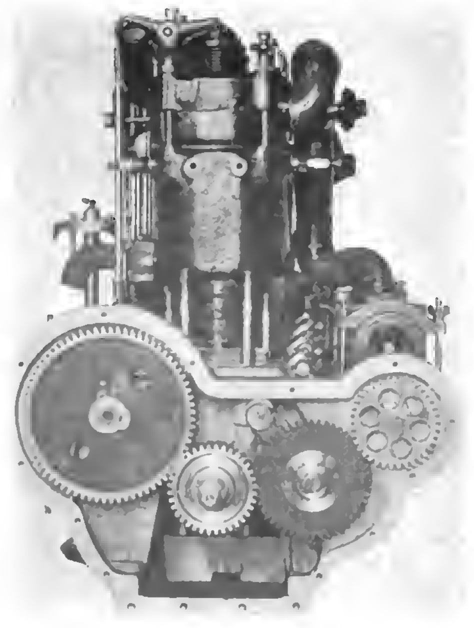
Rear Hub Brakes and Brake Drum

tem a gallon of oil will last for over 500 miles of ordinary running.

Transmission Three Speed Selective; Compactness a Feature—On Models R and S, the transmission used is of a new design, affording three speeds forward and reverse, operated along selective lines. A special feature is its compactness and the elimination of the use of a troublesome hollow shaft. The shafts and gears are made from nickel steel of large size, mounted on Hess-Bright and F. & S. imported ball bearings; the short shaft is only five inches between bearings, thus avoiding any liability of springing even under the most severe abuse. A transmission clutch brake is used to avoid clashing the gears in shifting from one speed to another.

Not the least of the good features with which this car fairly bristles is the straight line drive. This is obtained by setting the two rear supporting points of the power plant down low so that a straight line is described from the front end of the crankshaft to the rear axle, except the provision made back of the transmission for the drop at that end caused by the weight of the body and passengers. Throughout the car the very best of material is utilized, chrome nickel, nickel and other special steels, as well as high-class bearings, being used freely.

Changed is the steering gear, the one to be employed in the future being of the irreversible type as before, but operated by a double right and left hand thread with a rocker action at the base, which works the steering lever. The crossrod is placed at the rear of the front axle. The steering wheels are covered with hard rubber and are of large diameter, 18 and 19 inch being used.



End View of "R" Motor, Gear Cover Removed

Front axle is of high carbon steel, drop-forged to shape, which is the now popular I beam. The yokes are of the Elliott type with adjustable roller bearings. Massive steering knuckles formed by hand from nickel steel billets make for safety. The rear axle is of the semi-floating style with 1 1-2-inch shafts of nickel steel. On the axle double race ball bearings are used to give greater bearing contact and take up end thrust as well. Four of these are used on the axle and two in the pinion housing.

Alloy Steel Frame of Large Section—Frames are made of a cold-pressed alloy steel, admirably suited to the purpose and of large sectional area. Besides the front member which carries the forward trunnion of the power plant, there are but two cross members. Both of these are of steel and braced with heavy gusset plates where they join the main frame. Special efforts have been made to have the springing of the Knox cars as nearly perfect as human endeavor can make it. To this end semi-elliptic fronts and three-quarter elliptic rear springs are used. The front springs are shackled at the rear above the spring so that the shackles work in compression. The lower half of the rear spring is positively attached to brackets in front, while the upper half is bolted to a rigid gusset plate.

Realizing the importance of durable and reliable brakes, considerable experimenting has been done to have them first class in type as well as workmanship and material. One special feature is the construction of the drums, same being pressed from one piece of sheet steel, with an air space between the outer and inner drum, avoiding any possibility of either brake dragging, due to the expansion of the drum from heat when the other is applied. The service brake is a contracting band on the outside of the double drum, operated by foot pedal; the band is so fastened that it is pliable and free from rattle, and held free of the drums by springs. Adjustment is by turnbuckle, easy of access.

With a Runabout Body a Shorter Wheelbase, 102 Inches, Is Used

The emergency is a hand lever pull brake of the expanding type, operating on the inner drum, and easily and positively adjusted. Brake shoes and bands are lined with thermoid, and have perfect working equalizers; all rods and connections are free from rattle.

Model R, with standard equipment, including about $700 worth of parts ordinarily listed as extras, sells for $3,250. With different types of body, however, the price varies from $3,050 up to $4,000. The price of Model M remains the same at about $5,000. Specifications and prices for the new "six," Model S, have not yet been given out.

MEAN GAS SPEED IN MANIFOLDS AND PORTS

The loss due to friction of gas against walls is approximately as the square of the speed; since the loss of ability of a motor is materially affected by this friction, and since about ten per cent. of the power will be lost when the speed of the gas is about 4,000 feet per minute, the effect of a very high gas speed will be marked. While it is true that in motors of some repute the speed of the gas is maximum at 15,000 feet per minute, in steam practice the speed is kept down to 6,000 feet per minute, and in the better class of automobile motor designs, it is the aim to hold the gas speed down to about 9,000 feet per minute. Much depends upon the shape of the cams as well as upon the area of the ports, and as a rule it is better to so shape the cams that they will do the work properly, than it is to have large manifolds in conjunction with cams that are not well suited to the purpose.

P. & S. Town and Country Victoria, an Exclusive Model of Unique Design

IN all likelihood, there are few concerns which are forced into the manufacture of any one type or style of car, yet that is the peculiar position in which the Palmer & Singer Manufacturing Company, New York City, finds itself to-day. The Six-Sixty car built by this firm, has been so popular and such a good seller that owners of these cars, desiring a smaller and lower powered machine, have practically forced the company to build one for them. Not only did these enthusiastic adherents of P. & S. work, design, and material, force upon the concern a new type of car, but they contracted for a very large number of the new cars, before anything more had been done upon them than the decision to make a different car.

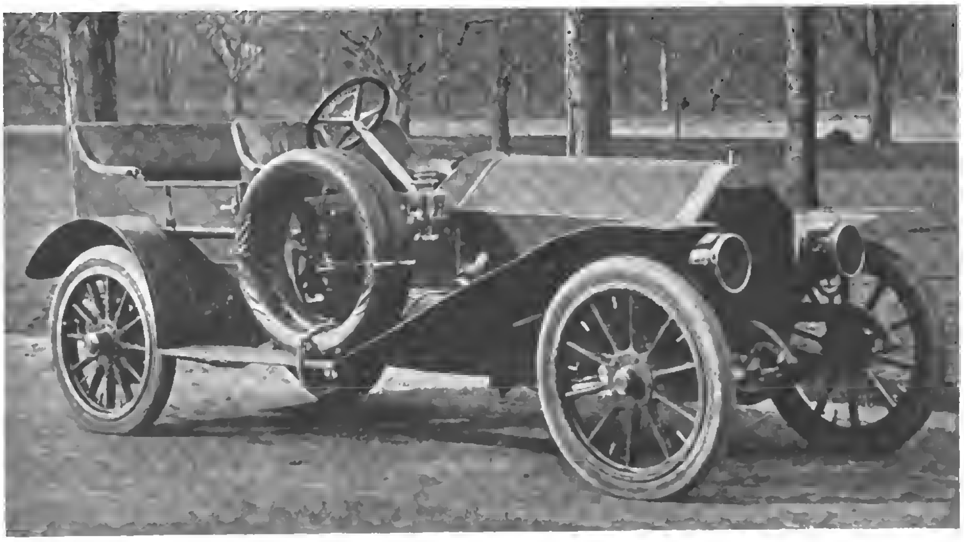
This condition necessitated a new and large factory, modern in every respect. So, land was purchased in Long Island City, at Webster, Second, and Third avenues, and the construction of the new shop started. This factory will be of fireproof construction, steel, brick, concrete, and glass only entering into its make-up. The edifice will be three stories in height, with sufficient floor space to accommodate 1,000 workmen, although, at first, many less than this will be transferred from the older buildings. In the selection and arrangement of the machinery which will form the greater part of the new equipment, much care has been exercised to have the result as nearly perfect as is possible. The labor-saving machinery is very complete and well-planned.

The present line of cars consists of but two, which are, however, fitted with numerous body style fitting them to the needs of every class of automobile enthusiast. These are the Four-Forty and the Six-Sixty. In the series for 1910 (the Palmer-Singer Company have no models, the various changes which mark the successive years being denoted by the series of cars going through the shop) two more cars are found. These are a Six-Forty and a Four-Fifty.

The former is the car which owners and friends have forced the company into the production of, while the latter is put out in response to a large demand for a four-cylinder machine of the very highest practicable power. Like their predecessors, these cars will have the tried and proven features which have made the name of Palmer-Singer famous in connection with automobiles of the highest type. Although it is not generally known, this company takes rank among the pioneer car builders, since it was among the very first to use a number of features which are now the standard. Some of these are: Four-speed transmission, which the majority of builders will use for the first time in 1910, but which this firm has always used; annular ball bearings throughout tbe car; universal joints on all steering connections; liberal use of nickel steel for axles and elsewhere; multiple disc clutch running in an oil bath; and many other features.

Model Four-Forty is powered with a four-cylinder engine, of 4 1-4-inch bore and 4 1-2-inch stroke. Ignition is by high-tension magneto, Bosch being the usual equipment. The transmission is four-speed selective, and with the engine is located on a subframe. To add to the strength of the main frame and at the same time preserve its light weight, the latter is made with longitudinal trusses. Between the engine and transmission is located the clutch, of the multiple disc variety, running in a bath of oil, which insures easy engagement. In addition to the usual full brake equipment, a hill pawl is fitted, which is dropped into engagement by the driver, using a small and inconspicuous hand lever. This prevents the car backing up, so that if the brakes should fail and the engine stop, when ascending a steep hill, there is no danger to the occupants of the car, since the hill pawl would hold it from backing down. As a two-passenger runabout, this chassis has a 107-inch wheelbase, and is fitted with 34 by 4-inch tires all around.

The Six-Sixty differs little from the smaller car, except for power plant and wheelbase length, as would be necessitated by longer bodies. The motor has a 4 7-8-inch bore and a 5 1-2-inch stroke, the length of the stroke relative to tbe bore making for slow speed and consequently quieter running. Wheel diameters are increased to 36 inches, while the front tire sizes remain at 4 inch. The rears, however, are increased to 4 1-4 inch to care for the slightly greater weight and carrying capacity. The wheelbase of 126 inches allows of any desired form of body, although the company fits a three-passenger runabout usually.



Baby Tonneau Body on Six-Sixty Chassis, 1910 Series

FRANKLIN AUTOMOBILES PERFECTED FOR 1910 SEASON

IMPROVEMENT being the order of the day, it is not strange to find the progressive H. H. Franklin Manufacturing Company of Syracuse, N. Y., on the spot with a few minor yet noteworthy additions to the well-known Franklin air-cooled cars. The improvements take the form of slight changes in the motor cooling system as mentioned briefly in the July 22 issue of THE AUTOMOBILE, in the ignition control, and a big improvement in the matter of wheel and tire sizes. This latter is along the line of modern changes which go toward making cars ride easier, and is made particularly noticeable in this case, since the cars already are very light in weight so that the old wheels are large, and tires ample for the weight carried. However, it has been fairly proven that larger wheels make a car ride easier, so the 1910 Franklins will have larger wheels. These larger wheels are also easier on tires, so that the increased wheel size coupled with larger tire diameters should eliminate all tire trouble.

A list of cars to be made and sold for 1910 would duplicate a similar list for 1909, since all models are continued, including: Model H, a six-cylinder 42-horsepower chassis, made with seven-passenger touring, close coupled, double rumble seat runabout, and limousine bodies; Model D, a four-cylinder smaller car of 28 horsepower, and fitted with five-passenger touring, close coupled, double rumble seated runabout, landaulet, and limousine bodies; and a high-grade runabout chassis, Model G, powered with a four-cylinder 18-horsepower engine, and equipped with the following body types: Four-passenger touring, six-passenger town, runabout with hamper, single rumble seat runabout, and double rumble seated runabout.

By far the most important of the changes has to do with the air-cooling arrangement. Formerly, the engine cylinders were cooled by the direct impingement of air upon thin sheet metal flanges radiating from the cylinder castings, the latter being machined on the outside to advance the cooling action and to allow of the flanges fitting closer. In this system, the air was forced against the flanges by means of the forwardly located fan, bevel gear driven from the front end of the crankshaft. The flywheel also assisted in moving the air past the cylinders at a high velocity, the clutch being very small, and the space between the exterior of the clutch case and the flywheel rim being made up of a series of spokes which have a fan blade shape. The newer way dispenses with the front fan, the flywheel spokes alone being used to move the air, but to do this most efficiently, a sheet metal casing has been placed around the cylinders and flanges, with very little clearance between its internal diameter and the outside size of the flanges. This casing is open at the bottom, and at the top the whole number of casings have been connected together with a diaphragm, which is carried back to the flywheel fan. The whole is made into an air-tight casing, except the openings left at the bottom for the admission of the air, and at the rear end, for the emission.

Another 1910 improvement is the elimination of the spark advance lever, which makes the ignition system much simpler than otherwise, as well as reducing the control to its simplest terms. In this manner, the judgment of the operator or driver as to the best spark position is done away with, and better results are obtained both as to maximum speed and power at all speeds. In the ignition group, the battery and coil are done away with. Dependence is placed wholly upon the reliable magneto, a Bosch high-tension, and the complication and added weight of the extra, in fact superfluous, system is saved.

Tire sizes have been much increased on all models. Last year, Model H carried 36 by 4 front tires and 36 by 4 1-2 rears, which have been changed to 36 by 4 1-2 tires in the front and the new odd size, 37 by 5, in the rear. Considering that the weight of this model complete does not exceed 2,700 pounds with touring body, the tires provided are unusually large.

Model D tires are increased from 36 by 3 1-2 front and 36 by 4 rear to 36 by 4 front and 36 by 4 1-2-inch rear. So, too, with the smaller car, all tire sizes have been increased by one-half inch.

Axles, springs, and frame remain the same, particularly the frame, which is of laminated wood. In this construction, selected second growth white ash is used, placed in three vertical laminations. In construction, these laminations are screwed and glued together, after which the whole is kiln dried, despite the previous kiln drying and seasoning process which the wood has gone through. The upper and lower edges are bound with a thinner strip which prevents the entrance of moisture into the grain of the wood and its consequent destruction. This frame is claimed to be lighter than the more usual steel frame and stronger as well. Certainly it yields to the rider, in the car so equipped, the desirable resiliency. As to springs, the full elliptic type, attached to the underside of the axles, which has long been a Franklin feature, will be retained without change.

All other features of Franklin cars in previous years have been retained, since they have survived the test of another year's daily service with complete satisfaction.

FRANKLIN SALESMEN CONFERENCE AND TOUR

When the branch managers, traveling salesmen, and factory representatives of the Franklin company held their recent conference at the big Syracuse factory, one day was spent in an outing which included a drive in the new 1910 models over some of the worst hills and roads to be found in Central New York. The drive, 75 miles in extent, ended at Chittenango Falls, where lunch was served on the ledge at the top of the falls, and just showing in the background of the picture. The long ride over bad roads served to try out the cars in an excellent manner, and the way in which they stood up was evidence that the new features incorporated in these models are right. The conference of the week was held under the direction of Sales Manager F. R. Bump, who, in the picture, stands at the left with cup in hand.

Group of Thirty-five Franklin Salesmen After Lunch at Chittenango Falls

NO MOTOR VEHICLE COMMISSIONER FOR CONNECTICUT

HARTFORD, CONN., July 26—The Senate of the Connecticut State Legislature, which is still in session, has without a doubt put away the commissioner of motor vehicles provision of the new State law. When the original bill was introduced, provision was made for the creation of the office of Commissioner of Motor Vehicles, entirely separate and with ample provision for absolute control of the situation, as far as the State was concerned. But this feature was a bone of contention, and a compromise was effected by providing for such an office but still leaving the control of matters with the Secretary of State. Like the bill proper it has dragged along until no one really cares a great deal anyway. But the machine has got to work, and is responsible for putting the commissioner bill to sleep for keeps. United States Senator Morgan G. Bulkeley, a former Governor of the State, was at the Capitol when the bill came up for action in the Senate. That was one side of the situation, and former Governor George P. McLean was on the other. The McLean faction favored the bill inasmuch as it was proposed to put in office George I. Allen, a former postmaster of Middletown. Now, then, it is generally assumed that Secretary of State Rogers is a Bulkeley faction man, which was obviously opposed to the bill. As might be expected, a lively time ensued. Senator Peck was in favor of having the work done in the Secretary of State's office rather than by a special commissioner, which latter, involving the installation of the commissioner and incidental office force would be a waste of good money. Without going into details, the measure was put to sleep by a big vote, so at all events it is very doubtful if there will be a commissioner of motor vehicles provided for at this session of the State Legislature. Both factions are headed by representative Republican leaders. It is intimated that an attempt will be made to prevent an appropriation being made for the Secretary's of State's office with which to control the motoring situation, as this would be such an easy way out of the difficulty and one that might be used.

OWNER NOT A CHAUFFEUR IN NEW YORK

ALBANY, N. Y., July 26—Automobile owners in general will be interested in knowing the text of the opinion of Attorney General Edward R. O'Malley on the subject of chauffeurs' licenses, and whether an owner or member of his family must take out a chauffeur's license to operate a car. The Attorney General's opinion was delivered in response to a request from Secretary of State Samuel S. Koenig, for information on the subject, and is as follows:

HON SAMUEL S. KOENIG,
Secretary of State, Albany, New York.

In answer to your inquiry of July 13., as to whether or not it is necessary for various members of a family who own an automobile to procure a chauffeur's license in the event that different members of the family operate the automobile, I am of the opinion that such license is not necessary.

There is no provision of law that I am aware of requiring the owner of a motor car or any member of his family to procure a chauffeur's license to run such machine.

Subdivision 5 of section 280, of Chapter 30 of the Consolidated Laws defines the word "chauffeur" as follows: "Shall mean any person operating a motor vehicle as mechanic, employee or for hire."

Section 282 requires the owner to file in the Secretary of State's office a statement of his name and address, with a brief description of the vehicle to be registered, etc.

Section 283 provides for the registration of such motor vehicle. Section 302 provides that every person desiring to operate a motor vehicle as a chauffeur shall file in the office of the Secretary of State a statement, which shall include his name and address and the trade name and motive power of the motor vehicle he is to operate. Upon filing such statement, the Secretary of State shall issue to the chauffeur a badge, as provided in section 304.

Section 306 provides that no person shall operate a motor vehicle as a chauffeur upon the public highways, unless such person shall have complied in all respects with the requirements of the four preceding sections.

There is no requirement that the owner of a motor vehicle shall procure a license to run the same, nor is there any requirement that any other person shall do so, unless he proposes to become a chauffeur or a person conducting an automobile as an employee for hire or wages.

EDWARD R. O'MALLEY, Attorney General.

[illegible]O SPEEDERS PUT "ON PROBATION"

[illegible], July 26—Imagine bankers, trust officials and others [illegible]ment in business and social circles making weekly [illegible] probation officer, like small boys caught swiping [illegible] a push cart. That is the latest idea of Police [illegible] of this city, before whom all speeders must ap[illegible] that fines had little effect, and tried the probation [illegible] Police Department has organized a motorcycle corps.

[illegible] **River Bridge Rebuilt**—The bridge across the [illegible] River at Conowingo, which was destroyed by fire in [illegible] will be opened for public traffic September 1. This [illegible] connecting link of the Maryland State road north and south of the Susquehanna River.

STATE AND LOCAL LAW IN PENNSYLVANIA

SWARTHMORE, PA., July 26—"Does a borough ordinance take precedence over the State law?" is a question which is now agitating the motorists of this country. President J. H. Weeks, of the Automobile Club of Delaware County, says that it doesn't. Squire Burnley, reinforced by the vast legal knowledge of the borough solicitor, avers that it does. The hullabaloo was raised by the arrest, at about eight o'clock on July 20, of W. R. Taylor, a member of the club, on the charge of driving his car without lights. The defendant does not deny the charge, but the club, through President Weeks, who has taken up the matter, asked for the dismissal of the proceedings on the ground that Section 12 of the new State law says vehicles must carry lights "from one hour after sunset until one hour before sunrise," and that as the sun did not set till 7.26 on the night in question, the defendant was still within the limit when arbitrarily arrested. The borough solicitor wanted to fine Mr. Taylor, and then remit the fine, charging the defendant with the costs alone, but the defense refused to accept this solution of the problem, preferring to pay fine and costs in order to have a groundwork for an appeal. The club and President Weeks are prepared to carry the case up to the Supreme Court on account of the principle involved. If every picayune borough and township ordinance is to be allowed to take precedence over the State law, which was carefully worded to prevent that very thing, President Weeks thinks the automobilists of Pennsylvania should know it as soon as possible.

OHIO PASSES 20,000 REGISTRATION MARK

COLUMBUS, O., July 26—State Registrar of Automobiles Fred. H. Caley on Friday, July 23, issued the twenty thousandth license to operate an automobile in Ohio. The number was granted to A. R. Davis, 2223 West Thirty-ninth street, Cleveland, an agent for the Studebaker line. Counting a population of 4,500,000 in the State, the use of 20,000 automobiles means there is one car to every 225 inhabitants.

According to a decision rendered by Attorney General Denman, all automobile tags must be plainly and conspicuously displayed. The ruling was given upon the request of the State Automobile Department, which has received numerous complaints of tags being hidden behind springs and swung parallel with the body of the car. Under the ruling these practices must be stopped. As the primary object of the law is identification nothing must be done to prevent an easy reading of the number of all tags. Such pernicious practices as oiling the number tags so that the rising dust will adhere to the oil, cover the surface, and thus prevent identification, will be stopped.

BLERIOT'S PASSAGE OF THE CHANNEL

The French journals have one and all worked themselves into a fine Gallic frenzy over M. Bleriot's very successful flight, and even the once unemotional English betray considerable excitement. Of course, Bleriot is a Frenchman, and, equally of course, England's pose of insular superiority has been badly damaged of late. Still none can doubt that this first passage of the English Channel by aeroplane is an event long to be remembered.

All scientific men have seen for some time that M. Bleriot's feat was perfectly practicable. The distance was a trifle, but 23 miles; and, although it had never been done, there was every reason to suppose that flying over water would prove easier than flying over land, as there would be none of the sudden and irregular air currents always set up by trees and tall buildings. The French government had volunteered to send a body-guard of swift torpedo boats. The only real difficulties to be anticipated were at the start and finish, where the steep cliffs might cause aerial disturbances. Wilbur Wright said that he could have done it long ago, and he is not a man given to vain talk. When prizes were offered and half a dozen aviators gathered to attempt the feat, it was only a question of time when one or the other of them would get across.

Nor need M. Bleriot's fame suffer by more mature consideration. The flight was not one to be accomplished by a novice. To attempt it required admirable courage and daring, and to succeed the knowledge and experience only to be attained by years of study, mingled with the dash and the enthusiasm of the born adventurer. M. Bleriot possesses all these qualities, and he has honestly won his fame. Meanwhile M. Latham should not be forgotten. He, too, had the courage and the enthusiasm, and he at least demonstrated that the aviator need come to no harm if his machine should stop in mid-channel.

One phase of the matter which has caused a needless flurry is the political effect. According to some, the Channel is narrower than in Napoleon's day; others claim that it has been obliterated, and that England now is on the Continent. All this is as unsubstantial as the German war balloon scare. There is no immediate possibility that aeroplanes will be made to carry more than two or three persons, and any extensive cargo of guns or explosives is out of the question. Some of these jingoists might work off a little energy in figuring the cost of equipping a fair-sized army with aeroplanes, at a thousand dollars apiece; not to mention the detail of training the necessary number of operators. The results will make the present Dreadnought craze look mild and innocuous in comparison.

The greatest importance of M. Bleriot's flight is not on the scientific, nor yet on the political side, but rather in its effect on the public mind. Hitherto people at large have looked on the aeroplane as a toy; interesting, and unquestionably able to fly, but incapable of any directed or useful effort. It needed the shock of just such an exploit to wake them to the possibilities of mechanical flight.

TALK OF GEARLESS CAR ON THE DECLINE

Not so very far back into automobile history there was much talk of the elimination of the transmission, this coming coincident with the rise of the six-cylinder motor. Now that the latter may be fairly said to have come into its own there is little heard about the lack of a necessity for speed changing devices, as was the case then. Rather, the inclination is in the other direction, for it is a noticeable fact that the number and quality of the users of four-speed gear sets increase, slowly, it is true, but nevertheless surely enough to be noticeable. With the advent of the low powered and low priced car, this question of number of speed changes will doubtless be renewed, for, desirable as a four-speed transmission would be on a car of this type, the additional weight, cost and complication over the three or even two speed gear would make its use out of the question.

Some light will be shed on this vexing problem by the present tendency in motor design, if continued along similar lines. At present there is a very pronounced leaning toward the long stroke motor. This would seem to be a high power at slow speed prime mover, which would have its effect on the transmission question. If the engine speed is slow and the gear reduction the same as is general now, there would be little use for numerous gear changes. In that case the probable outcome would be the use of a two speed sliding gear transmission. To consider this for a moment, it would be small, compact, hence easy and cheap to assemble, easy to repair or replace, and equally easy to keep in order. Aside from a large saving in weight, due not alone to the transmission, but also to the control, there would be an equally large economy in manufacturing cost, this undoubtedly redounding to the prospective purchaser's benefit.

PREPARATIONS FOR THE FAIRMOUNT PARK "200"

PHILADELPHIA, July 26—The Quaker City Motor Club is out with its prospectus of the second annual renewal of the 200-mile Fairmount Park stock chassis race, which, by reason of there being no Vanderbilt contest this year, promises to be the biggest race of the fall in the East. The club has decided to hang up $5,000 in cash, to be divided possibly as follows: 50 per cent. to the winer, 25 per cent. to second, 15 per cent. to third, and 10 per cent to fourth. Should any winner prefer to have a cup or plaque of equal value, he will be accommodated.

The proceeds will go to charity, the club, out of the entrance fees, paying all expenses of promoting and advertising, besides providing the prize money, preparing, oiling, and guarding the course, repairing any damage to the roads, etc. A committee of patrons and patronesses, to be composed of the most brilliant social lights of the Quaker City, will have complete charge of the grand stands, parking places, and all points of vantage whence the race can be viewed. Already this end of the affair is shaping up as a huge benefit, to boost the anti-tuberculosis fund and to aid other charities, and tentative plans look to so widening the scope of the event as to give the half million or more of spectators an opportunity to help along the worthy object.

It is hardly likely now that there will be any room for foreign cars, and that the same conditions as obtained last year will prevail. An effort will be made to increase the number of starters from 16 to 20 that a representative American field may line up for the word next October. Last year's field included two Locomobiles, two Loziers, and one each of Acme, Peerless, Pullman, Thomas, Studebaker, Chadwick, Stoddard-Dayton, Apperson, American Locomotive, Palmer and Singer, Pennsylvania, and Maxwell. Several cars not in the line-up last year are already assured. It begins to look as if there would again be a "waiting list." Certainly, with the fairest and best-policed course in the country, and an unexcelled management, the Quakers deserve well of the American manufacturers.

PLANS FOR LONG ISLAND DERBY TAKING FORM

W. J. Morgan, now the president of the Motor Contest Association, is organizing a road race for Long Island this fall, and says he has been assured of sufficient entries to make the event a success. The proposed circuit is between Riverhead and Mattituck, about twenty-two miles in length. The roads in the main are excellent, and there are but two sharp turns, dividing two ten-mile straightaways. Mr. Morgan thinks it will prove the fastest course in the country. The Suffolk county supervisors have been consulted and their consent secured. The date is to be September 21, so that the race will be an added attraction for the second annual "tour around Long Island." The policing of the course will probably be in charge of the Federation of American Motorcyclists. Owing to the distance of the course from New York, it is not expected that the crowd will be as unruly as at the Vanderbilt races. The course, however, is easily accessible by motor boat, as well as by automobile and train, and is said to possess many vantage points of observation for the sport-loving spectator.

The contest will be limited to cars selling between $2,500 and $5,000, and these will be divided into four classes, to run at different distances. The present plan calls for 100 miles by the small cars, 150 by the third class, 200 by the second class, and 250 by the big ones. Most of the 1910 models will be out by the time set, and it is expected that the entries will be largely recruited among these. The event will be known as the Long Island Derby. A definite announcement of the exact distances, the prizes, etc., is expected soon.

ATLANTIC CITY WANTS AN AUTODROME

Atlantic City, N. J., July 26—Spurred on by the success which seems to be in store for the Indianapolis and Atlanta projects, a company has been formed here to build a two-mile automobile track at Chelsea Heights, which in general appointments will excel either of those motordromes. The new company, at the head of which is Commodore Louis Kuehnle, of the Atlantic City Yacht Club, proposes to spend $800,000 in acquiring and filling in the ground, and $150,000 in building the track.

One hundred and fifty feet wide on the stretches, and one hundred and twenty-five feet wide on the banked turns, the track will have a concrete foundation to give it stability and permanence. A grand stand seating 25,000 people will also be erected. A huge garage, a club house, hotel, and chauffeur's quarters are also included in the plans. The property includes 526 acres, and work will be begun in time for an opening meet at the beginning of summer season at this popular seaside resort.

PREPARATIONS FOR WASHINGTON-BOSTON RUN

Washington, D. C., July 26—The rules governing the running of the Frank A. Munsey reliability contest from this city to Boston and return have been issued and given wide circulation. They are patterned after those governing this year's Glidden Tour. Entries have been received as follows: Chalmers-Detroit Motor Company, Chalmers-Detroit; Hudson Motor Company, Hudson "20"; Olds Motor Works, through Philadelphia branch, six-cylinder Oldsmobile; Jackson Automobile Company, through the New York branch, Jackson "40"; the Motor Company, Philadelphia, Premier; F. Windsor Eveland, Philadelphia, Stevens-Duryea; Charles E. Miller & Bro., Ford.

The Chalmers-Detroit pathfinding car has arrived in Washington, and will be sent out to blaze the route within the next few days. This battle-scarred hero, has jus returned from its strenuous trip from Denver to Mexico City, and it is attracting much attention on the streets of Washington. Carl Schnorr will drive the car on the pathfinding trip.

A number of well-known drivers have already been engaged to pilot cars in the Munsey contest. Among them are Tom Berger, who will be at the wheel of the big six-cylinder Oldsmobile; Ray McNamara will drive the Premier, while Frank Kramer, the well-known bicycle champion, will handle the Jackson.

CHEVROLET AND STRANG BREAK RECORDS

Lansing, Mich., July 27—At the Grand Rapids and Lansing races last Friday and Saturday, Louis Chevrolet and Lewis Strang carried off the honors. At Grand Rapids, Chevrolet, driving a Buick, broke the world's record for from ten to eighty miles on a circular track, covering fifty miles in 51:22. Strang's performance at Springfield the Saturday before, of 52:48, was the best previous record. At Lansing, Strang won the fifty-mile race with a 30-horsepower Buick in 52:19.

RICHFIELD SPRINGS CLIMB POSTPONED

The Richfield Springs, N. Y., hill climb, under the auspices of The Earlington, has been postponed from July 31 to August 7, on account of the conflict of the former date with the 24-hour race at Brighton Beach. The change was made necessary by the desire of a number of manufacturers to enter their best cars and drivers for both events.

Milwaukee Will Adopt Chicago's Plans for dust laying on its streets, boulevards and park roads, and will probably build a plant for making its own oil mixtures.

A. A. A. SOUNDS WARNING AGAINST RECKLESS DRIVING

DO automobilists understand the rules of the road? This question has been brought prominently before many automobile clubs within the last few days in view of the increasing number of accidents, some resulting in fatalities both to motorists and other users of the highway.

In many cases these accidents have been due either to ignorance of the ordinary rules of the road or to the supreme carelessness of automobile drivers in ignoring the simple regulations that conduce to safety. So flagrant has this tendency to recklessness become, in spite of the efforts being made by the leading clubs throughout the country to cooperate with city and county officials in observing the legal regulations, that a word of warning has been sounded by President Lewis R. Speare of the American Automobile Association, and his endeavors to control the present wave of recklessness have been seconded by the other officers and chairmen of the various A. A. A. boards.

"Many of the recent deplorable accidents might have been avoided by the observance of the simple road rules and sane driving," said President Speare. "There is also too much recklessness in crossing railroad and surface car lines, as well as passing electric cars in city streets when passengers are alighting. Again, many autoists in descending hills, even if not very long or steep ones, persist in keeping practically the full power of their motor on. If more motorists would throttle down the engine, or totally disengage it while descending a hill, the number of accidents from this source would be materially decreased. When the motorist suddenly finds himself in a tight place while descending a hill under full power or even partially so, and he loses control of his car, it is the most natural thing in the world to attribute the difficulty to the failure of the steering gear to work properly, whereas there would probably have been no trouble at all were the machine allowed to coast down gradually under its own momentum."

Some of the ordinary rules of the road which every motorist ought to know by heart and invariably observe are:

1. Keep to the right when overtaken by a passing automobile or other vehicle going in the same direction.

2. Keep to the left when about to pass another vehicle going in the same direction; in other words, the automobilist should pass another vehicle going in the same direction on the left-hand side of the vehicle passed.

3. Pass to the right when meeting a vehicle moving in the opposite direction.

Among the clubs that have recently been aroused to renewed activity toward preventing this widespread tendency to recklessness are the automobile clubs of Cleveland, Rochester and Syracuse. A vigilance committee has just been appointed by the Rochester Club, whose object is to deal severely with members and chauffeurs who persistently exhibit recklessness and carelessness in driving, and a vigorous campaign is also to be waged against autoists carrying fictitious numbers.

President W. F. Bonnell, of the Cleveland Automobile Club, has issued a general letter to all of the members, calling their attention to the fact that the city ordinances are being violated every day. So flagrant has this become that the chief of police in Cleveland has ordered that bulletins shall be issued every forty-eight hours giving the numbers of cars which have been recklessly operated. President Bonnell requests the members to cooperate with the officials toward suppressing this evil. "Cooperation in this," he says, "will be helpful to the automobile manufacturers, the individual owner of a car, and to citizens in general."

MAXWELL EMPLOYEES' PICTURES TAKEN

NEWCASTLE, IND., July 26—The employees of the Maxwell factory here turned out en masse last week to have their pictures taken, and it was certainly a job on a wholesale scale. There are said to be 2,300 men working there, and though all did not get in, the photographer still earned his pay. The automobile in the center of the group is occupied by Benjamin Briscoe, president; J. D. Maxwell, superintendent, and F. D. Dorman, secretary of the Maxwell Company, and Colonel K. C. Pardee. Around them are grouped the district supervisors and branch house managers of the company.

Striking Exhibit of the Development of the Automobile Industry—Photograph of the Officials and Employees of th

A. L. A. M. EXPERIMENTS TO OBTAIN QUIET MOTORS

THE engineers of the Association of Licensed Automobile Manufacturers have done a great deal of study and experimentation in the line of designing quiet-running motors, and have met with considerable success. One of the subjects of their experiments was the two-to-one gear set which is necessary on every four-cycle motor, which they found was a prolific source of noise.

Although the two-to-one gears do not at first glance seem to offer any designing difficulties, there are nevertheless some very important factors to be considered. Chief of these is the uneven or intermittent load due to the lifting action of the cams, causing intermittent and even reverse pressures on the gear teeth. To ameliorate this condition there must be considered the weight of the valve mechanism, the proper tension of the valve springs, the shaping of the cams to give smooth action to the valve plungers, and the proper pitch and lubrication of the gears and the permissible amount of back lash.

Some of the structural difficulties encountered are inaccurate machine work on the crankcase, causing variation in the distance between gear centers; unsuitable crankshaft and camshaft bearings, allowing the shafts to "jump" when the motor is running, and improper cutting of the gears themselves, causing them to warp after the strain of cutting the teeth is removed.

The principal cause of noise in the valves themselves is the too sudden impact of the valve on its seat. The descent of the valve should be arrested just before it strikes the seat, either by a slight rise in the cam or by a very gradual taper. The valve spring should be of sufficient strength to keep the roller in contact with cam. One leading experimenter says that with proper design the sound produced by the seating of the valve should not be heard at all with the manifolds in place and connected. The weight of valve for the best results is also an important consideration, and much may be accomplished by the suitable use of non-resonant material.

As for the rest of the motor, noise from pistons, connecting rods and crankshafts has been practically eliminated by proper design and accurate machine work, and proper lubrication and clearance.

APPLICATIONS READY FOR ATLANTA SHOW

ATLANTA, GA., July 26—Application blanks for the automobile show to be held here November 6-13 will be ready for distribution in a week or ten days, and will be distributed among the trade. All the details for this show, the first of importance ever held in the South, have been completed, and a decorative scheme is being planned that will be decidedly novel and will furnish a proper background for the first exhibition of the 1910 models. The show will be coincident with the opening of the new automobile track now under construction here. The general management of the show, which is under the auspices of the National Association of Automobile Manufacturers, will be in the hands of General Manager S. A. Miles and Alfred Reeves, and the Southern end will be cared for by Asa G. Candler, Edward Inman, and others. Applications for space may be made to the N. A. A. M., 7 East Forty-second street, New York.

A. M. C. M. A. SHOW COMMITTEE MEETS

The show committee of the American Motor Car Manufacturers' Association held a meeting at the New York office last Monday, at which the plans for the association's annual show next Winter were discussed. The show will be held in the Grand Central Palace and will open New Year's eve. Among other things, the decorative scheme was planned. S. H. Mora, chairman of the show committee, presided at the meeting, and others present were Benjamin Briscoe, D. J. Post, Motor and Accessory Manufacturers, and Alfred Reeves, A. M. C. M. A.

Pittsburgh's Public Safety Department is making life miserable for automobilists nowadays. Warrants were issued last week for more than 100 owners and drivers charged with either violating the speed ordinances or with having no drip pans on their cars. One day 350 autos were held up for examination.

Motor Company, at the Newcastle, Ind., Plant During Recent Convention of Maxwell Sales Managers

AUTOS IN MASSACHUSETTS' SUMMER MILITARY MANEUVERS

BOSTON, July 26—Plans that have been made for the annual Summer maneuvers of the Massachusetts militia, which will consist of a war game in the southeastern part of the State, with troops from New York, Connecticut, New Jersey and the District of Columbia as the enemy, contemplate the extensive employment of motor vehicles. Though the original plans, when it was expected that the maneuvers would consist of an attack on the coast, and in which motor vehicles were expected to play a most important part, have been abandoned, Adjutant General Grigham has not given up his idea of employing cars.

Briefly the war game consists in the landing of the troops from other States at Fall River and New Bedford with, presumably, the intention of marching on Boston. This will be the "Red army." Meantime, to defend Boston, the Massachusetts militia, constituting the "Blue army," will proceed from Boston toward Fall River and Boston, and the scene of activity probably will be in Bristol and Plymouth counties. In this section good roads are plenty, making it an ideal field for motor vehicles to demonstrate their value in military work.

For headquarters work Adjutant General Grigham has engaged the services of three White touring cars and a White ambulance, the negotiations having just been concluded by Manager J. S. Hathaway of the Boston branch. Walter G. Schmunk will be in charge for the White company, but a special officer detailed for the purpose will have charge of the cars in the field. These cars will be used for taking the officers from headquarters to any part of the territory that is being defended, and as the line probably will stretch out many miles, the service will require some long and speedy trips. They will also be used by the signal corps, for reconnoitering and for carrying despatches. While the maneuvers are on, all telegraph and telephone lines will be considered destroyed, so the commanding officer will have to send his orders and secure information by other means, and it is in this work that the cars are expected to prove most valuable. Private cars owned by officers of the different organizations also are likely to be used for similar purposes.

The problem of feeding several thousand men in the field, perhaps at a considerable distance from a city or from a railroad station, is to be a hard one, and the militia officers are negotiating with owners of motor trucks and expect to secure several of these vehicles for use during the maneuvers of August 14-22. Food of all kinds has been contracted for and will be transported by train to some point as near as possible to the expected center of activity during the maneuvers. From that point, however, it will have to be distributed to the various commands by motor trucks and by army wagons. The officers in charge believe that in this work the motor trucks can demonstrate an immense superiority over horse-drawn vehicles. Some of the separate commands are also trying to secure motor trucks, but the supply of these vehicles available is limited.

The motor cycle and the bicycle will be important in the maneuvers, and will be used to supplement the automobiles in scouting and in carrying despatches. It is planned to have a corps of motor cyclists and bicyclists attached to the headquarters of the "Blue army" and also to regimental and other headquarters, and soldiers who have motor cycles will probably be relieved from most duty, other than that incident to the use of their machines under orders from superior officers.

THE LATEST NEWS FROM OHIO'S GREAT TIRE-TOWN

AKRON, O., July 26—Local manufacturers confirm the announcement of an increase of 15 per cent. in the price of tires, but no complete price lists have been made public yet. Dealers have received new quotations, going into effect after July 16. The manufacturers say that a year ago the price of crude rubber such as was used in tires was less than $1 a pound, whereas, now it is $1.50, so that a raise in the price of the finished product is fully justified. The increase in the price of rubber was sudden, because the general depression kept the demand low; but when the demand again became brisk the price went up with a bound.

The new plant of the Falls Rubber Company, at Cuyahoga Falls, supplanting the old Superior Rubber Company of that town, will be ready to operate in three weeks. The officers are S. H. Sturgeon, president; W. G. Short, vice-president; H. F. Sechrist, secretary and treasurer, and William Sherbondy, superintendent, all of Akron. One of the products of the company will be a patented inner tube containing a layer of felt, for which great things are claimed.

The International Harvester Company this week started a final test of its new runabout of standard size, the machine, after a local test, being shipped to the central factory at Chicago to undergo the inspection of the company officials, to be followed by an inspection by the cost department that a sales price may be fixed. The new machines will be placed on the market next year, and will probably be named the International Runabout. It will be driven by a 20-horsepower four-cylinder engine. The car is of attractive appearance, and the color will be red. The company is also completing a touring car, and ran the first one to Albany, N. Y., this week, F. V. Kennedy, one of the prominent members of the company, driving the car. The International Harvester Company has a large plant here at present.

T. L. Pharr, of Pittsburg, drove his automobile fire engine from that city here this week for the purpose of equipping the engine with Swinehart tires. A test of the engine was made here, it working all right except near the canal it sank in the mud and some trouble was experienced. Stops were made at Newcastle and Youngstown on the way here. The engine is 115 horsepower, and when manned with eight men and 1,000 feet of hose weighs 9,400 pounds. It carries a 35-gallon gasoline tank, which the inventor claims will run the engine six hours, feeding four lines of hose. It also carries two four-gallon chemical tanks.

The Goodyear Tire & Rubber Company, whose tire and air bottle trade has grown immensely, has begun work adding two more stories to its office building. The plant was recently enlarged. All of the rubber tire plants in the city are making additions again this year.

The annual picnic of the Diamond Rubber Company was held on Saturday. The company gave 6,200 tickets to its employes for themselves and families. Free transportation was given to Silver Lake, where sports of all kinds were had with the shop men contesting. The Rubber Products Company, of Barberton, also run a free excursion to Brady's Lake.

Frank R. Tate, formerly of this city, has resigned as manager of the St. Louis branch of the B. F. Goodrich company to enter the automobile business.

A new product of the Diamond Rubber Company is an improved demountable rim. The company has also placed on the market an innovation in the form of a double tube motor cycle tire. The company has heretofore been making only single tube tires for motor cycles. The new tire has deep corrugations on the side to prevent side slipping. The company is having a very large demand for motor cycle tires.

What the Clubs Are Doing These Days

'FRISCO CLUBS TO HAVE NEW QUARTERS

San Francisco, July 26—Members of the Western Automobile Club are rejoicing in the fact that they will soon have the Jefferson Square building on Golden Gate avenue transformed into a club house for their use. The club, which is composed of autoists from this and surrounding cities, has taken over the building containing 100,000 square feet of floor space. It will have swimming tanks, gymnasium, library, bowling and billiard rooms, and apartments for members on the two upper floors. The lower floor will be given over to club appointments. The officers of the club are Louis Mooser, president; and Dr. R. G. Hubbell, W. V. Lloyd, S. M. Samter and W. N. Wright constitute board of directors. The membership is limited to 500.

Interest is being taken in the forthcoming contest in Alameda county in September. Among the star entrants is to be Percy J. Walker, a well-known amateur, who will drive the Grand Prix Benz car in the race, providing the contest will be an open one. He will drive a 60-horsepower stock car of the same make, however, if only such cars are allowed to participate.

GOOD ROADS AND AUTO CLUB IN ONE

Jackson, Miss., July 26—Automobile owners of this city and nearby towns have formed the Hinds County Good Roads and Automobile Club. While the formation of the body was inspired by the automobilists, its membership is not limited to them, and, in fact, a determined effort will be made to enroll all users of the highways. The club will become actively engaged at once in the spreading campaign for better roads in the South. The following officers were elected: President, Eugene Simpson; vice-president, R. S. Withers; secretary, W. D. McRaven. A committee composed of George C. McLaurin, of Clinton; H. L. Hicks and Floyd Williams, of this place, was appointed to consider the feasibility of macadamized roads through this section. Another committee, composed of R. S. Withers, of Clinton; Mason Birdsong, of Bolton, and J. C. Landen, of Jackson, was selected to prepare plans for the government of the club, and for launching a membership campaign.

MILWAUKEE CONSIDERING A CLUB-HOUSE

Milwaukee, Wis., July 26—The Milwaukee Automobile Club will meet in special session Thursday evening, July 29, to make a final decision in the matter of building a clubhouse. There has been some difficulty in obtaining an expression of sentiment as to the advisability of mortgaging the club's present properties to cover the cost of a building, but proxies will be legal at this meeting, and the vote will be final. The club owns a five-acre tract at Blue Mound and Cottrill avenues, west of Milwaukee, which would be a perfect location for a building. The clubhouse that is being planned would cost $12,000.

Thirty of the cars that participated in the parade at the Racine, Wis., Homecoming early this month will be entered in the parade to be held here August 3-7. There will be three sections, floral, novelty, and comic, and several hundred dollars are offered in prizes.

BINGOS TO HAVE INFORMATION BUREAU

Binghamton, N. Y., July 26—The automobile club of this city proposes to establish in the office of the chairman of the touring committee an information bureau for the gratuitous use of tourists passing through here. The latest maps, route books, etc., will be kept for reference, and the bureau will keep informed as to speed traps, road closings for repair and other items of interest to tourists.

HAMILTON, ONT., ORPHANS GIVEN A RIDE

Hamilton, Ont., July 26—The orphans of this city had the time of their lives at the outing given them by the Hamilton Automobile Club last week. About 300 of the youngsters turned out. Owing to a laughable mistake, they got a longer ride than was bargained for. The president and secretary of the club had laid out the route to what they thought was Oaklands Park; but when the procession arrived they found that it was really Bay View, and that the caterer was miles away. The trip to the real Oaklands was made in record time. Indoor baseball, football and foot races were the features, and a magnificent supper topped off the day.

HARTFORD CLUB GIVES ORPHANS AN OUTING

Hartford, Conn., July 26—Last Tuesday afternoon the Automobile Club of Hartford held its long-deferred annual orphans' outing. Several previous attempts had been blocked by bad weather. About 150 children from the Hartford asylum were the guests, and even more cars than were needed turned out. After the parade through the city the procession headed for Goodwin Park, where the children were turned loose. There were abundant refreshments and everybody had a good time.

GENEVA, N. Y., HAS A WIDEAWAKE CLUB

Geneva, N. Y., July 26—Sixty cars turned out for the "joy ride" of the Geneva Automobile Club, which passed through Phelps, Newark and Palmyra and arrived in Canandaigua in time for supper. It was one of the most enjoyable events that the club has participated in. Later the automobilists of Newark, N. Y., who contemplate organizing a club, visited Geneva in grand style and were received by a brass band; after a parade through the city a joint banquet was held, at which the mayor spoke, and much good roads talk was indulged in.

COLUMBUS' CAREFULLY COMPILED BOOK

Columbus, O., July 26—The Columbus Automobile Club has issued the first number of *The Bulletin*, which was announced some time ago. The booklet is attractive with plenty of advertisements and all the live news of the club. Handsome cuts of the interior of the club are printed as well as the annual report of the secretary and treasurer. A full roster of the membership is one of the features.

AUTOISTS OF ALLEGANY, MD., ORGANIZE

Baltimore, July 26—The Automobile Club of Allegany County has been formed with fifty members. It will be a branch of the advisory council of the Automobile Club of Maryland. The president of the new organization is H. H. Amack, and W. C. Devecmon is secretary.

TRUMBULL, O., AUTO CLUB GIVES BANQUET

Trumbull, O., July 26—The Trumbull Automobile Club, one of the strongest organizations in the Western Reserve, held a big banquet last week at which more than a hundred guests were present. The club is doing good work in the vicinity.

AUTO CLUB ORGANIZED AT ALTOONA, PA.

Altoona, Pa., July 26—The Altoona Motor Club has been formed by automobilists of this city. The officers elected are: W. L. Hicks, president; E. J. Lomnitz, secretary, and W. W. Blake, treasurer.

Salesman Holden and His Business-Getting Stearns

A "STEARNS CHASE" THROUGH FOUR STATES

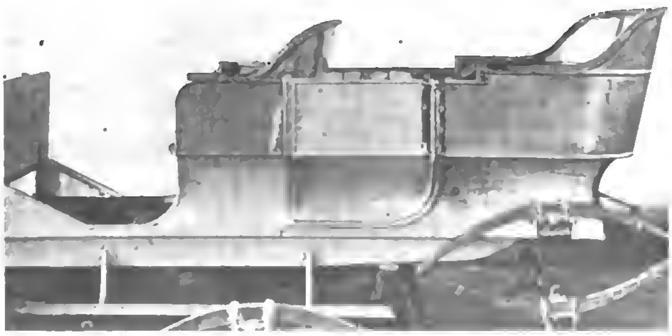
A. S. Holden, one of the district salesmen of the F. B. Stearns Company, kept his 30-60 shaft-driven Stearns on the road continuously from May 29 till July 17. Leaving Cleveland on the former date, he drove through Columbus to Cincinnati, through West Virginia, back again through Ohio and into the coal regions of Pennsylvania to Pittsburg. After spending considerable time in that vicinity he kept on through Ligonier and through New York State back to Cleveland, via Erie, Pa. In its fifty-one days on the road the car averaged 85 miles a day, and for three consecutive days it averaged 210 miles. It ran perfectly from the start, no attention having been given it beyond filling the tanks. He will start again shortly in the same car, and expects to make another trip of the same length.

DETROIT COMPANY FOR COMMERCIAL CARS.

Detroit, Mich., July 27—A new automobile company has just been organized here, in which the principal movers are the officers of the Chalmers-Detroit company. The new concern will be known as the Fairview Motor Car Company. The capital stock has all been subscribed, and work will be started at once on a $150,000 plant. The new company will manufacture commercial vehicles and taxicabs.

A TOURING BODY OF CAST ALUMINUM

The touring bodies to be fitted to the 1910 Marmon cars almost completely dispense with the use of wood. This material is only found in the mahogany dash, the floors and a thin strip between the body and the steel chassis frame. All the rest of the body is of metal, the lower panels and the doors being of cast aluminum, and the upper panels of sheet aluminum. This construction makes impossible any shrinking or warping, with consequent misfits of doors and seats, and is stronger.



Cast Aluminum Bodies Used on 1910 Marmon Cars

WITH THE REGAL ON WESTERN PRAIRIES

Denver, Col., July 24—When the Regal transcontinentalists planned their schedule they overlooked two factors that seriously interfere with adherence to the timetable. The first has been with them ever since leaving New York in the shape of friends and the general public, who, with their entertainments, consumed several hours each day. The second, the Iowa gumbo has just appeared in its malignant form after the heavy rains throughout that section. Still the car keeps on schedule and is covering the road in great shape.

The transcontinentalists left Chicago at noon on the twelfth, and, passing through Aurora and Rochelle in good time, finally stopped at Morrison. The next morning, after a short run, they came to the Mississippi, only to find a twenty-foot gap in the bridge, which the foreman of the repairing gang told them would take at least two hours to close. Of course it was nearer three hours before the last plank was down and they were able to continue their journey. The next day's run was to Cedar Rapids, and after that the schedule named Carroll, Ia., as the stopping place. Night found them, however, at Boone, fifty miles short, and for good reason, as the rains had converted the roads into bottomless quagmires of the purest gumbo. Several times the Remy magneto was submerged in muddy water, but it never refused to spark.

Transcontinental Regal Following Prairie Trail

The day after leaving Omaha was spent principally in crossing and recrossing the North Platte River, which winds over half the State. Here they overtook in mid-continent a car bound for Seattle and another from New Mexico headed for Detroit. The Seattle car joined forces and they continued together nearly to Ogallala. The roads became impassable, and the tourists were forced to take to the prairie alongside, leaving behind them a trail of cut fences and choking alkali dust. At Sterling they found the nicest and cleanest little hotel of the trip—a godsend to weary travelers.

Leaving Sterling a rain drenched them for the first time since leaving New York, relieving the heat and making the sand more passable. They went up a long hill late in the afternoon and at the top they found themselves facing the main chain of the Rockies. To the north Long's peak and to the south Pike's Peak loomed up majestically. The sun broke through the clouds as it was setting behind the range and clearly defined the magnitude of this great wall of mountains, which set across the path to the coast like a forbidding wall. Denver the tourists reached at 7 p. m., 2367 miles out from New York in 13 1-2 days' driving.

Dixon, Ill.—Alderman James Gaffney has started the erection of an up-to-date garage on East First street, between Ottawa and Crawford avenues.

Six-Story Addition to Stoddard-Dayton Plant, Now Building

When the new structures are completed the Dayton Motor Car Company, Dayton, Ohio, will have 100,000 square feet increase in floor space. This will accommodate 400 additional workmen, and $75,000 in new equipment is ready to take its place on the floors.

Extra Bodies Are Popular—An idea which seems to be growing in popularity is that of having two bodies, one open and one closed, to be used interchangeably on the same chassis. The Pierce-Arrow Motor Car Company of Buffalo reports that about 22 per cent. of its orders during the past season called for extra bodies. The Pierce chasses are the same for all touring, landaulet and limousine models, so that a man buying a car for delivery during the Summer months can have an open touring body for the warm weather and in the Fall can substitute for this a closed body. The advantages of this idea appealed to President Taft when ordering his car. He had a touring body built for his six-cylinder, 48-horsepower Pierce landaulet, and this has now replaced the enclosed body used in Washington during the inauguration.

Ford Victor Fire-Scarred—The Ford which won the New York-Seattle race had a narrow escape from ending its career once and for all at Prosser, Wash. Just after crossing a district known as "Horse Heaven"—decidedly not a heaven for automobilists—Scott and Smith, the drivers, stopped at this town to take on gasoline. The usual crowd gathered, and one bone-headed individual struck a match on the tank. Instantly the car was in flames, and nothing could be done until it had burned itself out. Luckily the machinery of the car was not injured. The tank's usefulness was ended, however, and for the rest of the journey the fuel had to be carried in a can on the footboard.

Firestone Makes Demountable Rims—The Firestone Tire and Rubber Company is sending out to the trade blue-prints and other matter descriptive of the Firestone demountable rim. The Firestone Company recommends the use of quick detachable tires in connection with this rim because they are so much easier to remove and replace. It is prepared, however, to supply the rim with regular clinchers on order, although it is difficult to fit these with the short-stem staybolts required. Another booklet contains in fac-simile form telegrams received from the Ford and Acme drivers in the recent New York-Seattle race, telling of the excellent service their tires are giving.

Wayne and Northern Parts—A. L. Austin, formerly connected with the Northern Automobile Company and with the E. M. F. Company, and A. O. Dunk have organized the Auto Parts Company, of Detroit, to be located at St. Antoine street and the Michigan Central Railroad. The company has purchased from the E. M. F. Company all parts, drawings, patterns, jigs and special tools for making replacement parts of Wayne and Northern cars and will devote its particular attention to repairing cars of these two makes.

Grabowsky Sells Treasury Stock—The business of the Grabowsky Power Wagon Company, of Detroit, has developed so rapidly that it was recently found necessary to offer for sale all the treasury stock in order to obtain sufficient working capital. The stock was quickly taken up by Detroit capitalists, and the directors are now thinking of increasing the stock from $300,000 to $1,000,000. The present increase of capital will be employed in building an addition to the factory so as to effect a considerable increase in next year's output.

New Tire on the Market—The Ohio Tire Company, with a capital stock of $10,000, has been incorporated under the Ohio laws by Thomas Midgley, B. G. Huntington, Louis Fink, J. A. Pfeifer and M. E. Murphy. Mr. Midgley is general manager of the Midgley Mfg. Co., of Columbus, which manufactures the Midgley automobile wheel. The new company will locate a factory in Columbus for the manufacture of a tire which is said to embody many improvements.

Milwaukee Buys Two Cars—The Milwaukee common council has authorized the purchase of a Pierce-Arrow touring car for the use of the bureau of detectives. The department also has an auto patrol wagon in service. The purchase of a Peerless touring car for the joint use of council committees and the board of public works, after being delayed several months by injunctions, has finally been authorized and paid for.

Large Order U. & H. Master Magnetos—As an indication of the prospects for 1909, the J. S. Bretz Company, New York City, reports an order from the Interstate Automobile Company of 3,000 U. & H. master magnetos. All through the West, among the makers of cars, the demand for magnetos is brisk, indicating that many cars are to be put out for next year and magnetos will be regular.

Interesting Registration Figures—The records of the secretary of state of Wisconsin show that up to June 1, 1909, 7383 cars had been registered in that State. In point of numbers the Rambler leads, having 733 to its credit, with the next three makes in order having 697, 598 and 487 respectively. Illinois has already passed the 10,000 mark, and in this State, too, the Rambler leads.

Fisk Tires in Racing—A number of entrants in the coming 24-hour race at Brighton Beach will use Fisk tires and rims. These have in the past been used more by tourists than by racing drivers, but the latter seem to be recognizing the value of the bolted-on type of tire, as these have been represented in more contests this year than ever before.

Kinsey Ready for Business—The new plant of the Kinsey Mfg. Co. at Toledo, O., will be ready for occupancy August 1, at which time 100 men will be started. The company has just been incorporated with a capital of $100,000 by Isaac Kinsey, H. V. Hawk, Willard Corbin, W. C. Smith and J. N. Van Deman.

Oily Hospitality—When the Glidden tourists passed through Jackson, Mich., the American Oil Company of that city gladdened the heart of each driver with a present of a gallon can of oil, a pound box of grease and a pound of waste.

A Carriage-Builder in Line—The L. Burg Carriage Company, of Dallas City, Ill., has taken up the manufacture of automobiles and will have both touring and roadster models. The Rutenber motor will be used.

IN AND ABOUT THE AGENCIES

Studebaker, Philadelphia—In anticipation of the expected large increase of business due to the advent of the Studebaker-Flanders "20," and the taking over of the E-M-F car from the Foss & Hughes Motor Company. Manager E. V. Stratton, of the Philadelphia Studebaker branch, is preparing for an extensive enlargement of the present quarters.

Packard, Hartford, Conn.—Milton J. Budlong, president of the Packard Company, of New York, is authority for the statement that the Packard Company will establish a branch in this city. The location has not been determined. It is understood that R. B. Sloan, of the New York branch, will be manager.

Rambler, New York City—The retail business of the Homan & Schulz Company has been taken over by the Rambler branch house in New York, located at 38 West 62d street. The branch will continue to handle as before the Rambler wholesale business throughout the East.

Empire Tires, Philadelphia—The Empire Tire Company, of Trenton, N. J., last week opened a branch house at Broad and Wood streets, Philadelphia, with E. B. Richardson as manager.

Continental Tires, Omaha, Neb.—The Continental Caoutchouc Company, New York City, announces that it has appointed the Baum Iron Company, of Omaha, Neb., distributing agents for Continental tires and rims in the State of Nebraska.

Hotchkiss, New York City—J. W. Delamater, manager of the Hotchkiss Import Company, has completed the alterations in the garage at 20 West Sixtieth street, which is to be the home of the Hotchkiss.

The Standard Automobile Company, of Pittsburgh, Pa., will establish a branch house in the Deveeny building, in Uniontown, Pa. It will have an agency for Peerless, Mitchell and Baker electric.

Hudson, New York City—The A. Elliott Ranney Company, metropolitan agent for the Hudson, has leased a suite in the Automobile Building, 1777 Broadway, and will take possession August 1.

Jackson and Babcock, Houston, Tex.—P. J. Lea, W. T. McKallip and Elmer Abbey have organized a company to take the agencies of the Jackson and the Babcock electric.

Jewel, Pittsburgh, Pa.—The Jewel will hereafter be shown in Pittsburgh in the Banker Automobile Palace block on Baum street, E. E., which will be ready about August 1.

American, New York City—The headquarters of the American Motor Sales Company have been removed to the northeast corner of Broadway and Fifty-seventh street.

PERSONAL TRADE MENTION

Ernest Coler has assumed charge of the Maxwell-Briscoe Motor Company's new publishing department. The growing interests of the company have made the creation of the new department desirable. Mr. Coler, who has looked after the Maxwell's publicity for the past two years, will continue to publish *The Co-Operator*, and will also be responsible for most Maxwell literature.

Berry Rockwell, late of the Railway Steel Spring Company, and well-known through his work as field secretary of the Sacramento Valley & Eastern Railway Company, and secretary of the Hotel Knickerbocker, New York, has accepted the position of advertising manager, Maxwell-Briscoe Motor Co.

A. L. Bolster, who has been connected with the Fisk factory at Chicopee Falls, Mass., ever since the organization of that company, has succeeded K. B. Harwood as manager of the Philadelphia branch. The latter will devote his energies to special outside factory representative business for the Fisk company.

Edwin E. Peake has been appointed manager of the Regal Sales Company of Detroit, which is to control the sales of the Regal car in Michigan. He was formerly connected with the sales department of the Buick Motor Company.

C. H. Hill, formerly with the Cadillac Company of New York, has left that company to take a position with the Haynes Automobile Company.

RECENT BUSINESS CHANGES

The Motor Car Company of New Jersey has dissolved partnership. In future the business will be managed by W. V. Snyder, Jr., who will retain the agency for the Matheson. The withdrawing members, M. Uppercu, C. Fisher and E. G. Ward, have formed a new concern, which is to handle the Cadillac.

Standard Thermometer Company, Boston—This company, at 65 Shirley street, Boston, has purchased the speedometer business of the Parker Mfg. Co., of the same city, and will continue to conduct the business on the same principles as heretofore.

Auto-Automatic Windshield Company Moves—The Auto-Automatic Windshield Company has moved its offices to 870 Woodward avenue, Detroit, in the new George building, which will be devoted exclusively to the automobile trade.

TAXICABS AND TRANSIT

Hartford, Conn.—Taxicabs are constantly increasing in numbers here, and the horse cabbies are complaining bitterly. Many of the garages operate taxicabs of the Maxwell, Mitchell and Elmore makes and have all the business they can handle.

Pittsburgh, Pa.—The incorporators of the Pittsburgh Taxicab Company intend to increase the capital of the concern from $100,000 to $200,000. The company has been very successful this summer.

RECENT MICHELIN VICTORIES

Continued success of Michelin tires in every form of road and track contest has been emphasized again by a large number of victories within the last thirty days. The list includes first and third places in the 290-mile Denver Motor Club stock car road race, July 5; the 100-mile track record at Columbus, O., July 3; the kilometer, the mile and the free-for-all at the annual meet at Wildwood, N. J., also on July 5, and the 25-mile Canadian championship at Montreal, July 9. At the Illinois State Fair Meet, July 10, Michelin tires won the 5-mile and the 50-mile contests.

In the Indiana Trophy road contest on June 18, over 232.74 miles of Lake County, Indiana, roads, Michelins secured first, second, third, fourth and fifth places, and first, third, fourth and fifth in the competition on the following day for the Cobe Trophy over the same course, but totaling 395.66 miles.

At Readville, the Harvard Trophy and a new 25-mile world's track record were secured by Michelins, as well as the Bailey Trophy for winning the Owner's 5-mile stock car contest. The Automobile Trade Trophy, too, was gathered into the Michelin camp. This was a free-for-all stock car event. Four other numbers of less importance were also captured.

The Point Breeze Meet saw a wide variety of contests, and De Palma established a new track record on Michelins. Other events won on these well-known tires at Point Breeze included a 100-mile contest, two for 10 miles, one each of 50 and 5 miles.

RECENT INCORPORATIONS

Imperial Motor Car Company, Hamilton, O.—Incorporated with a capital stock of $500,000 to manufacture automobiles, by C. U. Carpenter, Stanley Helvey, G. E. Helvey, G. A. Rentschler and F. B. Rentschler.

Chicago Taxicab Company, Chicago—The Chicago Taxicab Company has filed a statement announcing that its capital stock has been decreased from $3,000,000 to $500,000.

Grout Automobile Company, Orange, Mass.—Capital, $150,000. To take over the business of the Grout Brothers Automobile Company.

Sauer Motor Trucks, West Orange, N. J.—Capital, $200,000. Incorporators: W. D. Sargent, G. M. Judd and E. H. Fallows.

Crow Motor Car Company, Elkhart, Ind.—Capital, $50,000. Incorporators: E. C. Crow, F. A. Howe and M. E. Crow.

Animated Scene in Hudson Motor Car Company Testing Yard Adjacent to the Detroit Factory

This newly-formed company has already received deposits from actual purchasers of over one thousand cars, and so has found it necessary to push the factory organization to the limit. The above scene in the testing yard gives a very good idea of the prevailing activity, necessitated by plans and contracts to deliver four thousand cars during the balance of this year and next.

VOL. XXI NEW YORK—THURSDAY, AUGUST 5, 1909—CHICAGO No. 6

THE AUTOMOBILE

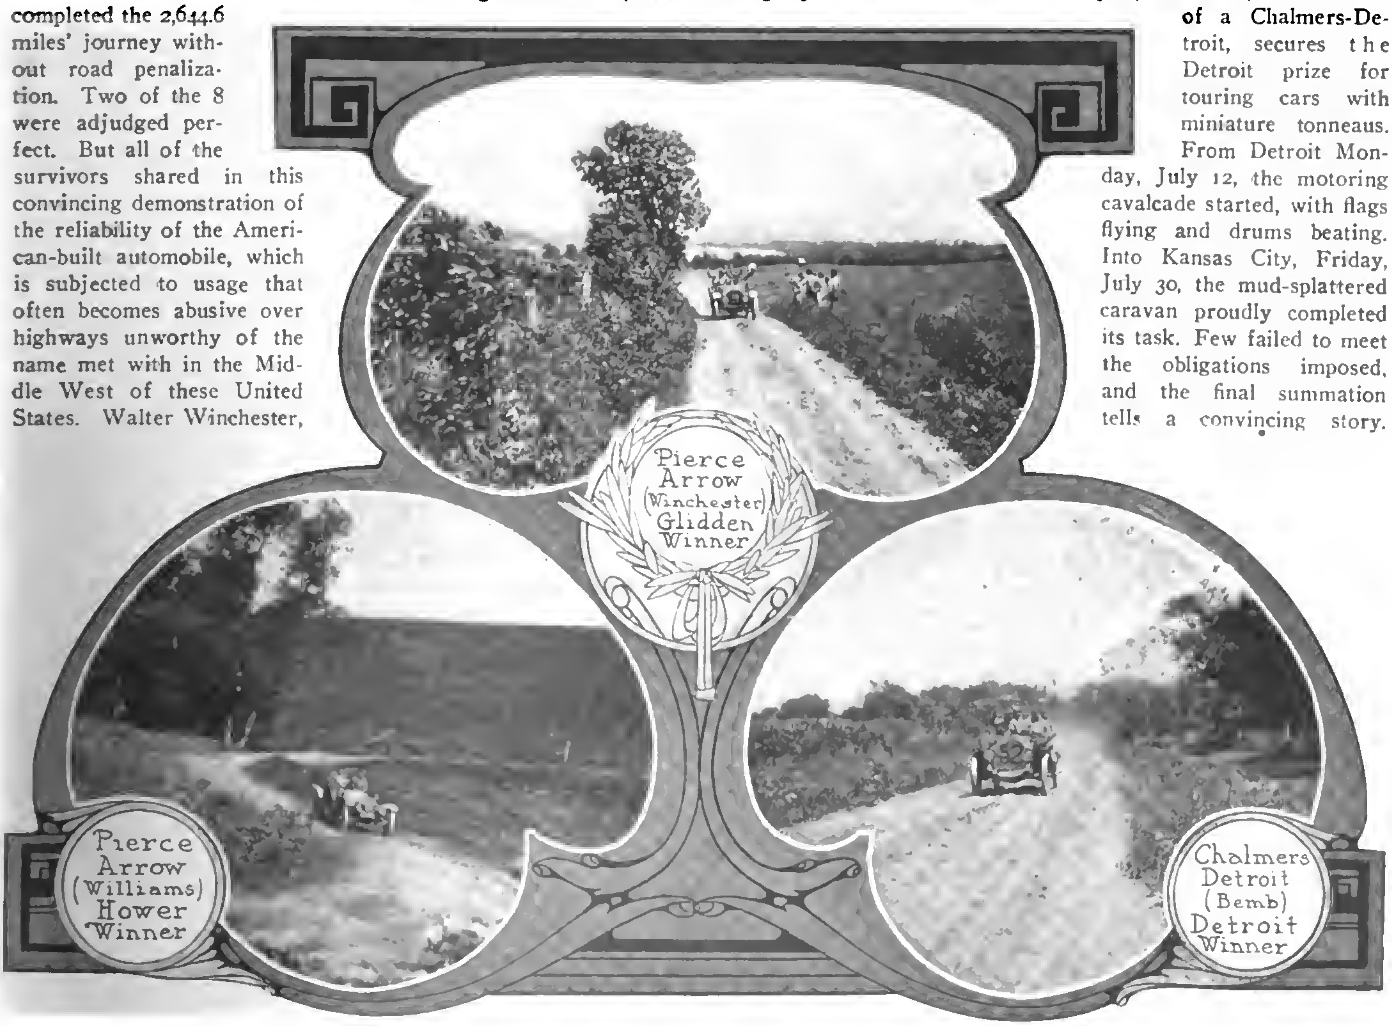
BIG TOUR ENDS WITH THREE WINNERS

Pierce Arrow (Winchester) Captures the Glidden Touring Car Trophy. Pierce Arrow (Williams) Takes the Hower Runabout Cup. Chalmers-Detroit (Bemb) Secures the Detroit Toy Tonneau Prize

EIGHT AWARDED PERFECT ROAD SCORES

No. 9 Pierce Arrow, No. 2 Premier, No. 8 Pierce Arrow, No. 5 Marmon, No. 1 Premier, No. 108 Pierce Arrow, No. 101 Moline, No. 109 Pierce Arrow

TWENTY-FOUR of the 30 contestants successfully accomplished the Sixth Annual Reliability Touring Contest of the American Automobile Association. Eight of the 24 cars completed the 2,644.6 miles' journey without road penalization. Two of the 8 were adjudged perfect. But all of the survivors shared in this convincing demonstration of the reliability of the American-built automobile, which is subjected to usage that often becomes abusive over highways unworthy of the name met with in the Middle West of these United States. Walter Winchester, driving a Pierce Arrow, obtains possession of the famous Glidden trophy. John S. Williams, piloting another Pierce Arrow, gains the glory of the Hower runabout cup. Jean Bemb, at the wheel of a Chalmers-Detroit, secures the Detroit prize for touring cars with miniature tonneaus. From Detroit Monday, July 12, the motoring cavalcade started, with flags flying and drums beating. Into Kansas City, Friday, July 30, the mud-splattered caravan proudly completed its task. Few failed to meet the obligations imposed, and the final summation tells a convincing story.



RELIABILITY was the marked characteristic of the Sixth Annual Touring Contest of the American Automobile Association, which started at Detroit, July 12, and ended at Kansas City, July 30, after a journey which totaled 2,644.6 miles.

Eight cars completed this diversified and strenuous passage without road penalizations of any sort. This is the list: No. 9 Pierce Arrow (Winchester); No. 2 Premier (Hammond); No. 8 Pierce Arrow (Dey); No. 5 Marmon (Marmon); No. 1 Premier (Jay); No. 108 Pierce Arrow (Williams); No. 101 Moline (Wicke); No. 109 Pierce Arrow (Schofield).

Of this octette, two mastered the minute technical examination without the loss of a single point: No. 9 Pierce Arrow, driven by Walter Winchester, and emerging as the winner of the Glidden trophy in the touring-car class; No. 108 Pierce Arrow, piloted by John Williams, and winner of the Hower cup for runabouts. The penalties imposed upon the remaining six detracted but slightly from the achievements of the cars.

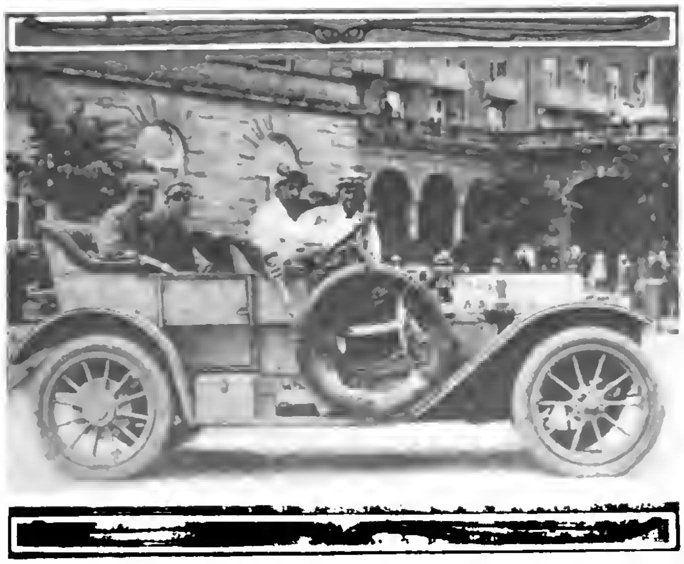
In the competition for the Detroit prize, for cars fitted with small tonneaus, none of the trio had a perfect score, and No. 52 Chalmers-Detroit, Jean Bemb at the wheel, came through with the smallest penalization, closely pursued by No. 53 Premier, handled by C. Waltman.

With four of eight perfect road scores, and with two flawless survivors, the Pierce Arrow secured the largest amount of glory and secured it through sturdy cars, capable drivers and general all around excellence.

Of the three Premiers competing, two finished with unsmirched road travelling, and the technical penalizations imposed upon two of the three were such as to cast no discredit upon their running qualities.

The two Marmons finished fourth and fifth in the grand total of the Glidden, with penalizations that were provoking rather than serious.

In the Hower competition, the two Molines and the Lexington were so close up to the winner as to call for condolences at the infinitesmal things which prevented a clean bill of health. But in deciding the possession of a single prize there could be only one winner, though in a competition of such a prolonged kind the entire field of finishers is entitled to credit in generous quantities. Surely no road competition ever held before in this country imposed such exacting and variable conditions as those which confronted the participants in the 1909 tour. Roads of every known variety, in conditions ranging from ideal down to the most wretched substitutes for highways, were included in the twenty-six hundred odd miles travelled.



Howard Marmon and the Perfect Road Score Marmon

Michigan had good cause to be ashamed of its alleged roads. Illinois contributed very bad and very good ones in the short mileage through that commonwealth. Wisconsin proved considerable of a surprise, with uniformly good going and attractive scenery. Minnesota was crossed at an opportune period and gave perhaps the greatest enjoyment of the entire tour. Iowa, too, was traversed with satisfaction, again principally because of excellent weather conditions. Nebraska contributed some good roads and a supply of nondescript prairie progress. Colorado had several good stretches, but for the most part it was a case of lonesome tracks across scrubby plains. And, finally, Kansas did fairly well, with a concluding day that was the toughest of the entire trip.

Such knocks and twists and strains as the cars withstood emphasized the recent advance in American automobile construction. The route for the most part passed through sections of country never before visited by a big endurance tour. The interest aroused was apparent on all sides. Entertainments, almost too profuse in number, punctuated the two-day stops at Minneapolis and Denver, to say nothing of the preliminary festivities at Detroit and the concluding functions at Kansas City. Intermingled were other events at Madison, Wis.; Mankato, Minn.; Council Bluffs, Ia.; Kearney, Neb., and Salina, Kan., not forgetting lunches and other mid-day contributions received en route at innumerable places.

Of course, Chairman Frank B. Hower had to be chairman in his own way, which means that he ran the tour more or less according to his own ideas. A good man with him, for the last half of the trip, was S. B. Stevens, a board member of considerable experience in automobile competition. Dai Lewis scattered the confetti as only he can do it, and his unfailing buoyancy of spirits did much to keep many in humor whose noses occasionally got slightly out of joint. E. L. Ferguson, who always does the starting, had to drop out of the procession at Kearney, Neb., because of an accident that placed him on the retired list. Thereafter, "Mort" Reeves, the chief observer, assumed most of "Fergy's" duties.

In the technical examination at Kansas City, Henry Souther and Joseph Tracy had a difficult task which was executed with as much satisfaction as could have been given by any other two men as capably qualified to do the work. They did not pretend to interpret the rules, and whenever in doubt they called upon the chairman to make a ruling.

As to whether there will be a 1910 tour, there exists a conflict of opinion, though the general concensus is that something of this nature is still needed by the automobile industry. Some are satisfied, some are disgusted, and some are indifferent.

Kansas City Entertained Tourists—The technical examination of the cars in Convention Hall somewhat interfered with the entertainment planned by the Automobile Club of Kansas City, but there were a substantial number at liberty to enjoy the warm hospitality. The reception began on the outskirts of the city, when each arriving car was decorated with American flags, and as the cars checked in the occupants were furnished with credentials. One particularly appreciated was a card stating: "We hate to offer you water, but our cool marble pool and shower baths are at your disposal. The Kansas City Athletic Club." Then there was a book giving the freedom of the city, with a printed key, from the Mayor; and a program of the entertainment. A smoker in the evening at the Coates House opened the festivities. Saturday was marked by a morning jaunt, as guests of the city, over its magnificent oiled boulevards, the ride being followed by a buffet luncheon. There was a race meet at Elm Ridge in the afternoon, and Electric Park, with a Dutch supper, was the evening attraction, with automobile rides Sunday for those who desired them.

Lexington Which by a Minor Incident Lost Its Perfect Score Near Kansas City

TWENTY-FOUR OF 30 CONTESTANTS FINISHED THE RUN

KANSAS CITY, MO., Aug. 2—Eight of the thirty cars which started from Detroit averaged one mile every three minutes until Kansas City was reached, with five of the daily runs exceeding 200 miles. In giving credit for this remarkable traveling over varied road surfaces, attention should be called to the fact that it was done without adjustment of any kind to the cars other than permitted by the rules, which confined the work to adjusting carbureters, cleaning the gasoline line if it became clogged, cleaning of spark plugs, and the adjusting of brakes.

Although only eight finished with perfect road scores, there were twenty-four of the original thirty cars running at the finish of the tour. All honors, however, does not belong to the eight which finished with perfect scores, as some of the others did nobly.

One in this class not to be overlooked was No. 114 Lexington, a car brought out in May of this year, but which throughout the tour ran with a perfect road score until within 20 miles of Kansas City when a cotter pin working out necessitated a stop to replace it, not a bit of new material having to be used. This car passed a particularly enviable technical examination, and all of the penalties were for tightening parts which undoubtedly had suffered somewhat from vibration during the long tour.

The same story might be repeated with reference to many of the other cars, as a host of the troubles which entailed penalties at the final examination were for tightening of parts that had worked loose. This vibration would not have occurred with ordinary road conditions, but on the plains of Colorado and western Kansas the cars had to travel over water courses across the road anywhere from 6 inches to 3 feet deep, at times 18 inches of water flowing through some of these. Besides, there were a score or more of dried-up sandy creek beds, into which the cars had to dip and which racked not a few of them severely.

A careful analysis of the road troubles and the final technical examination show conclusively that continual vibration caused most of the troubles and that these troubles were not in the actual breaking of parts, but just in the loosening of them. Had the rules permitted of the tightening of nuts and adjusting of parts, but prohibiting the use of any new material, there would have been sixteen perfect scores at Kansas City instead of two.

The work of the four Pierce cars was commendatory from start to finish. Winchester's No. 9 and Williams' No. 108 went through with perfect road scores and passed a perfect technical examination. Williams was in the van of the tour every day, catching the official car repeatedly before the night control was reached. Winchester was always well up in front, so that neither of these cars were nursed throughout the entire trip. Although the other two Pierces, namely, No. 8 driven by Dey and No. 109 driven by Schofield, had perfect road scores, they were penalized in the technical examination. Dey's troubles were slight, one being the starting crank which was bent when dropping into a dried-up creek bed and the other was a bonnet hinge. The No. 109 car suffered from vibration, replacing a tool box torn off when dropping into a deep dried-up creek bed, and also requiring a new spring clip.

Of the three Premier cars entered officially in the run two came through with perfect road scores, and the other, No. 53, had troubles consisting of a leaking gasoline line where it rubbed against the mud apron, a broken spring, and putting on a fan belt. Both of the perfect score cars, Nos. 1 and 2, driven by Webb Jay and Harry Hammond, respectively, made over half of the run without fan belts and did not experience any trouble with heating, taking on not more than a pint of water on any day's run. On next to the last day of the run Jay broke a rear spring and was compelled to make the whole of the last day's run with the car resting on the bumper, which, considering the rough nature of the roads, was a particularly gruelling test and undoubtedly resulted in added technical penalization. All of the parts penalized in the technical examination originated from vibration. No. 2 Premier had nothing wrong in the technical examination but to replace a broken spring clip and put on a fan belt. No. 53 Premier's troubles were entirely due to vibration. During the run these cars maintained a conservative pace, starting out midway of the tour and finishing anywhere from

The Premier Trio, of Which Nos. 1 and 2 Finished with Perfect Road Scores

No. 101 Moline, One of the Perfect Road Score Cars

one-half to one hour ahead of schedule. The spring trouble which developed was unexpected, though the springs used were of a new kind that were being tested out.

Both of the Marmon cars behaved with special credit from start to finish and took a particularly clean technical examination. No. 5, driven by H. C. Marmon, had a perfect road score, and No. 4, driven by F. E. Wing, experienced but one road trouble, the loosening of a flange on the gasoline feed pipe. This was the sole trouble for the two cars on the entire trip. In the final examination the only point found on Wing's car was a piece about 3 inches long broken off the end of the bottom leaf of a spring. On No. 5 Marmon the same spring leaf had a portion broken off, and in addition there was a slight penalty for straightening a spring hanger and tightening one end of the tie rod between the steering knuckles.

A car performance that created considerable attention throughout the West in that it is a Western product was the triple Moline entry in the Hower, bearing Nos. 100, 101, and 102. No. 101 made a perfect road score. No. 100 had a sole road trouble, a piece of metal getting between the timing gears, which, when removed, had not damaged the gears, so that they were not changed or even repaired. No. 102 had an equally slight trouble which occurred twice and consisted in a taper pin holding one of the timing gears in place dropping out. To reinsert it called for considerable work, but the timing gears were not injured, and no new parts other than a pin were needed. In the technical examination the troubles, as discovered, were equally slight. A noteworthy feature about these cars is that they made the entire run without carrying spare parts of any nature, not even an extra spark plug, an extra cotter pin, or an extra bolt.

The road work of the three Chalmers-Detroit cars was particularly favorable, excepting No. 3, the Glidden entry, which burned out a connecting rod bushing and had trouble thereafter until the car was withdrawn on the ninth day. No. 52, which won the Detroit trophy, had only one road trouble, and that when the locking ring holding the bearing race on the commutator released, so that the balls on the commutator were lost, and thereafter the car made the complete trip on the magneto. In the final examination this car showed no troubles other than some loosened parts due to vibration. No. 105 in the Hower ran with a perfect road score until the last day when, within 100 miles of the finish, tire troubles ditched it, a wheel was damaged, a new one borrowed, and the car disqualified for using a borrowed wheel. This borrowed wheel was taken from the Chalmers press car, which had the wheel repaired in a blacksmith shop and completed the tour to Kansas City.

The work of the two Maxwell cars, No. 6 in the Glidden and No. 107 in the Hower, was noted daily. No. 6 had but one trouble which robbed it of a perfect road score and that was the breaking of a spring. Shock absorbers were not used on these cars. The only trouble with No. 107 on the road was a spring clip, a broken spring, and tightening a water gasket. In the technical examination the troubles of these cars appeared to be solely due to vibration. Both of these cars maintained a conservative pace throughout the run and were generally well ahead of their running schedule.

The No. 14 White had as its chief mission in the tour the demonstration of kerosene as a feasible fuel, which fuel was used from start to finish and which the driver was able to obtain at every crossroad store, at a price ranging from 6 to 8 cents less than the figure asked for gasoline. The car had but two road troubles, one on the run out of Denver, when the oiler tube had to be cleaned, and another towards the last, when a fender had to be wired up. In the technical examination the car had to have several parts tightened. This car had an unusual amount of tire trouble on the road which was apparently not due so much to the tires nor the car as to nail-catching, with which other cars shared.

The only two-cycle in the run, and one which made a particularly creditable road performance, was No. 51, American Simplex, contending for the Detroit trophy. This car would have had a perfect road score had it not been for its dropping into a deep water trench on the day's trip out of Denver. This seriously damaged the base of the radiator and loosened the steering gear, but outside of this the car had not a single instance of road trouble. In the technical examination the car received a heavy penalty for the radiator repair, and the only other penalty imposed was for a couple of broken spring leaf clips.

No. 12 Midland, in the Glidden end of the contest, had a perfect score on thirteen of the fifteen days of the tour, and the only trouble was due to a broken fender iron and a dent in the mud apron, which occurred on the Madison-La Crosse run. This car was one of the leaders into the night control on many days of the tour, and undoubtedly would have been first into Kansas City had it not been for striking a stone out of Lawrence, which destroyed a tire and badly damaged a rear wheel. Notwithstanding this the car was third at the finish and completed the day with a perfect score. In the technical examination this car was penalized for tightening several running gear parts, and had to replace two fender irons, a rear wheel, and the starting crank.

A car which suffered particularly from road penalties, but which completed the tour, and had no troubles whatever with the motor, transmission, or power plant, was the No. 10 Glide. Its troubles were all with the front springs and the spring seatings on the axle, which caused penalties from Denver on. In spite of having made several days' runs with broken springs, the final examination brought out very few defects in this car. It was indeed creditable that a car with front spring trouble should have shown so few troubles due to vibration at the completion of the run.

The only two-cylinder car to officially complete the tour as a contestant was No. 112 Mason, which made thirteen perfect score runs out of fifteen and had but two road troubles. One was a minor affair consisting of the breaking of a petcock; the other on the thirteenth day was the burning out of a bushing on a connecting rod. In other respects this car made a splendid road showing and invariably ran away ahead of its schedule. The car was never nursed along the road. In the final examination the penalties were very meager, requiring a new lamp bracket, tightening two front spring clips, replacing some cotter pins in the driving chain, and repairing a leak in the radiator.

The two Jewel entries, Nos. 7 and 111, had thirteen and eight perfect score running days, respectively. No. 7's road troubles were minor, consisting of work on a fender, and a couple of flange bolts on a wheel. No. 111 had trouble with its tire carriers, changed a spark plug, tightened some hub flange bolts, and did some work on its gas pump. The majority of the penalizations in the technical examination were occasioned by vibration as in the other cars. No. 7 was penalized for a new frame sidepice.

THE SUMMING UP OF THE TOUR

GLIDDEN TROPHY

No.	Car	Driver	Road	Technical	Total
9	Pierce-Arrow	Winchester	0	0	0
2	Premier	Hammond	0	1.5	1.5
8	Pierce-Arrow	Dey	0	1.6	1.6

a left rear wheel, spring clips, and tightening some other parts. Of the cars that withdrew from the contest only one checked into Kansas City with the regular party, this being a Brush runabout, although the other checked in shortly after. No. 11 Thomas, driven by Amateur Buse, had a perfect score until the eleventh day, when a repair was made on the gasoline line, and it had no more trouble until the 13th day, when it withdrew, due to breaking sub-frame members when it struck a water trench. The Hupmobile withdrew, due to transmission troubles, on the run to Minneapolis; and the McIntyre motor buggy withdrew on the run into Madison owing to trouble with the steering gear when the car was ditched. The Rapid truck kept along with the party until Denver, when it went ahead to take the ascent to Pike's Peak, after which it did not touch the tour until Kansas City was reached. The arrival Sunday night in that city excited much attention and favorable comment.

PREMIER AND MOLINE PROTEST AWARDS

BUFFALO, Aug. 2—Alleging that Pierce cars Nos. 9 and 108 did not carry full manufacturers' specifications, protests have been filed by H. O. Smith, president of the Premier Motor Car Company, and W. H. VanDervoort of the Moline Automobile Company. The point in question is regarding tail lamps, which, it is claimed, were not carried for several days after dropping or breaking off, and that the two Pierce Arrows were not required to put them on, thus to incur a penalty for work.

The Premier protests from a Glidden class view, in that one of its cars took second place; and the Moline protests the Hower award, as a Moline finished second. Should it be decreed that the tail lamps must be placed, it is reasonable to suppose that the work would take less than a minute, so that no change would be made in the relative position of the contestants except that it would eliminate all perfect scores.

A Typical Early Morning Start—Leaving Hugo, Colorado, en Route to Oakley, Kansas

ROAD AND EXAMINATION PENALTIES OF THE TOUR

According to the rules of the competition the penalties, as announced at the finish, are divided into those given on the road and those resulting from the technical examination. The former include marks for lateness at any night stop, on a basis of one point per minute; marks for work done upon the cars at a rate of one-tenth of a point per man per minute, except upon material not carried at the start when the penalty for work was doubled; and penalty for material used, at a rate of one-tenth of a point per ten cents worth, or fraction, except that outside material was charged at double price.

In the technical inspection the plan was to put the contestants in safe and first-class running order, as they were at the beginning, with penalties for work and material. In the hurry at the finish of the tour there was some confusion in scoring and the result anounced in Kansas City has been somewhat changed. In the examination-penalties the material has been made to read at double the regular price, as required by the rules, but the clause requiring double work-penalties upon these materials was neglected. It may be that the Contest Board will decree an alteration, although it is not likely that the relative standing of the contestants would be greatly changed.

As the committee went over the cars they gave the entrants the choice of taking the penalty which they imposed, in regard to the amount of work necessary to replace or repair any part, or of trying to beat this by actual work. E. O. Hayes made a record when instead of 30 minutes to change a wheel on his Midland he took four and a half, thereby saving 2.5 points from his total score. Another example of quick work was that in which Roy Snyder, in one minute instead of five, tightened two spring clips on his Mason. In many cases the drivers were satisfied that they could not take successful issue with the technical men on these points. Herewith is the detailed story:

Repairing gasoline feed pipe, 5 min	.5	
Material, one nut	.1	
Tightening rear wheel cone, 1 min	.1	
Withdrawn, 1,000 points	1,000.0	2,251.6

105 CHALMERS-DETROIT
ROAD
Disqualified, last day, for use of outside wheel.

WHAT PARTS THE CONTESTANTS CARRIED

IN order to keep close watch upon the amount of repairs necessary for the contestants, each car had its spare parts sealed in canvas bags. Before leaving Detroit the entrant was required to give an itemized list of the extras and show them to the chief inspector as they were placed in the receptacle. If at any time it was incumbent upon the driver to use something from the spare parts bag, the observer made note of the opening and of the materials requisitioned. At the completion of the tour the bags were turned over for inspection to the same man who had sealed them. Some of the cars carried few extras and in some cases none.

The list is as follows:

GLIDDEN TROPHY

NO. 1 PREMIER—2 low tension igniter plugs, 2 jump spark plugs, 1 valve cap yoke, 1 valve spring, 1 valve.

NO. 2 PREMIER—Same as car No. 1.

NO. 3 CHALMERS-DETROIT—2 rolls of copper wire, 1 box cotter pins, 1 roll tire tape, 1 coil solder wire.

NO. 4 MARMON—1 carbureter air valve, 1 air valve spring, 1 carbureter guide, 1 carbureter nut, 1 valve, 1 valve spring, 1 valve washer, 2 split valve washers, 1 fan belt, 2 spark plugs, 1 ball bearing, 1 piece water pump packing, 4 spark plug gaskets, 2 valve cover gaskets, 2 shoulder pins, 13 nuts, 5 cap screws, 9 taper pins, 10 washers, 12 cotter pins, 4 pieces rubber hose, 3 hose couplings, 1 piece annealed wire, 1 can "Smooth-on."

NO. 5 MARMON—Same as Car No. 4.

NO. 6 MAXWELL—Right and left steering knuckles, right and left steering knuckle arms, 2 large and 2 small steering knuckle cones, 1 drive shaft yoke, 1 pinion shaft yoke, 2 sets universal yoke pins, pin locks, pin lock screws, 1 driving pinion support complete, 1 inside and 1 outside ball races complete, Splitdorf carbon brushes and copper brushes, 1 front and 1 rear spring, 1 universal cross, 2 steering knuckle cone lock nuts, 3 steering arm nuts, 4 spark plugs, 2 spring straps, 97 cotter pins, 1 magneto breaker arm and screws, 1 roll tape.

NO. 7 JEWEL—1 D. W. F. bearing, 1 valve, 1 valve spring, 1 fan belt, 1 coil copper wire, 1 box cotter pins, 1 roll tape.

NO. 8 PIERCE ARROW—6 spark plugs, 1 inlet valve complete with spring, spool and cotter, 1 exhaust valve complete with spring, spool, and cotter, 1 fan belt, 1 package cotter and taper pins, 1 master vibrator spring.

NO. 9 PIERCE ARROW—Same as car No. 8.

NO. 10 GLIDE—1 double steering arm, 1 single steering arm, 4 roller bearing cones, 8 valves, 1 package emery, 3 fan belts, 1 package assorted washers and screws, 1 front spring, 3 front spring clips, 9 spark plugs, 1 box assorted washers and cotters, 1 package soft wire, 5 feet rubber hose, 1 roll tire tape.

NO. 11 THOMAS—4 spark plugs with gaskets, 4 countershaft keys, 1 chain, 2 F. S. ball bearings, 1 aluminum water pump connection, 6 hose clips, 18 inches rubber hose, 1 foot copper pipe, 3 pieces rubber hose, 6 sheets emery cloth, 1 bag assorted nuts, bolts, and pins.

NO. 13 MIDLAND—2 upper and 2 lower rear spring clips and nuts, 2 front spring clips, 2 front spring shackles, 2 front spring bolts and nuts, 1 right and 1 left steering spindles, 10 spark plugs, 1 set magneto parts, 1 box cotter pins, nuts, washers, soldering set.

NO. 14 WHITE—1 vaporizer, 2 pilot lights, 1 small spring, 1 box packing, 1 coil wire.

DETROIT TROPHY

NO. 51 AMERICAN SIMPLEX—26 nuts and pins, magneto carbon holder, 1 spool copper wire, 3 adapters, 6 spark plugs, 12 spark plug gaskets, 1 piece 1-4 inch brass pipe, assorted cotter pins, 1 muffler cut-out spring.

NO. 52 CHALMERS-DETROIT—4 spark plugs, roll tape, box cotter pins, roll copper wire.

NO. 53 PREMIER—Same as car No. 1.

HOWER CUP

NOS. 100, 101, 102 MOLINE—One roll copper wire each.

NOS. 103, 104 BRUSH—1 cam gear and shaft complete, 1 transmission coupling, 1 spring post, 1 chain, 2 pair connecting rod bushings, 5 Winkley oilers, 2 large and 2 small bearing cones, 4 meter links, 4 set screws, 1 sprig and bracket, 5 valve springs, 1 right front spindle, 1 grease cup, 1 starting ratchet, 8 step bolts, 11 carriage bolts, 2 commutator springs, 2 starting crank pins, 5 check nuts, 15 lock washers, 88 steel balls, 2 spindle adjusting nuts complete and 2 screws, 1 roll tape, 1 box assorted keys, 1 carbureter complete, 3 spark plugs, 20 feet copper wire, 1 valve.

NO. 105 CHALMERS-DETROIT—8 spark plugs, 1 roll tape.

NO. 106 HUPMOBILE—1 carbureter, 1 magneto, 2 shackle bolts, nuts, and washers, 4 spark plugs, roll tire tape, roll copper wire, 1 piece emery cloth, 2 complete sets front roller bearings, 1 complete set rear roller bearings, 1 front spring clip complete, 1 radius rod complete, 1 transmission sliding member, 1 cross steering connection complete, 4 hand-brake-to-shaft pins, 1 rear wheel axle pin, 1 clevis pin, 2 right and 2 left adjusting cones with 1 nut each, 1 stationary cone and washer.

NO. 107 MAXWELL—Same as car No. 6.

NO. 108, 109 PIERCE ARROW—Same as cars Nos. 8 and 9.

NO. 110 McINTYRE—10 axle clips and bolts, 1 set transmission fibers, 4 rocker arms complete, 4 crank base bearings, 4 valves and cotters, 2 piston pins and bushings, 4 valve springs, 2 connecting rods with bushings, 6 piston rings, 4 cylinder head gaskets, 1 transmission gear complete, 1 high speed clutch, 4 roller bearings, 2 gasoline pipes, 1 grease cup, 4 differential bushings, 2 radius rods, 10 feet ignition wire, 4 grease cups, 1 push rod with rollers, 3 valve spring discs, 1 steering rod bolt, 1 knuckle bolt, 12 cap screws, 4 check valves for oiler, 4 taper pins, 15 feet driving chain, 24 chain repair links, 1 carbureter, 2 wire belts, 2 spark plugs.

NO. 111 JEWELL—8 spark plugs, 1 fan bolt, 2 rolls tire tape, 1 box cotter pins.

NO. 112 MASON—1 pair rear axle bearings, 6 valve springs, 2 valves, 1 set valve parts, 4 spark plugs, 15 chain links, 5 feet magneto cable, 16 bolts nad nuts, box cotter pins, 1 connecting rod and main bearing bushings, 1 valve lifter roller and push rod complete, 1 front and 1 rear spring clip, 1 pot cock, 1 roll tire tape, 1 piece solder, 1 coil wire, 1 magneto timer, 2 battery connectors, 1 roll tire tape, 2 brake pins, 1 valve pin, 1 sheet emery cloth.

NO. 114 LEXINGTON—1 fan belt, 2 rawhide strings, 10 spark plugs, 4 sheets emery cloth, 1 box valve grinding composition, 1 roll tape, 10 spring bolts with nuts, 2 spring shackles, 4 yoke ends, 1 turnbuckle, 4 valve springs, washers, and keys, 2 gasoline shut-off cocks, 4 gasoline connections, 72 bolts, nuts, and screws, 11 rivets, 132 cotter pins, 41 lock washers, 3 carbureter throttle screws, 4 carbureter needle valves, 3 air valve springs, 1 air valve adjusting screw and nut, 1 Woodruff key, 1 tubing connector.

Midland Passing Through Topeka, the Capital of Kansas, on the Final Day of the Run

THE THREE FINAL DAYS THAT CONCLUDED THE TOUR

OAKLEY, KAN., July 28—Across the prairies the lessening cavalcade came to-day from Hugo, Col., after one of the toughest runs since the big tour started July 12 in Detroit. The open country traveling between Colorado Springs and Hugo had been comparatively easy, and this gave rise to the hope that to-day's run would be equally uneventful. The first 30 of the 165 miles to this night stop supplied the most treacherous kind of roads. Vegetation hid deep holes, and of ruts there were innumerable ones that scraped the bellies of the cars, and shook machines and occupants until they ached in concert.

Near Aroya deep ravines nearly put several cars out of the reckoning, and other fordings interspersed the hard journey. About half way Colorado was bidden adieu with mingled regrets and thanks, and for a time it looked as though Kansas prairie might be an improvement. Perhaps it was, but nevertheless there was some difficult going en route here, and all felt relief when they caught sight of the line of Pullman sleepers alongside the typical Union Pacific station. Kansas presented more rolling prairie than did Colorado, but as a whole this automobiling on flat country becomes monotonous, especially with a torrid sun shooting its rays earthward at over a hundred degrees. Rain threatened during the afternoon, which caused the sky to become partially overcast and somewhat curbed the stifling atmosphere. The few towns passed through found the people from the country round gathered to catch a sight of the "Gliddenites," who accepted with blasé indifference the homage of the "common people," who unfortunately knew not that this was the result of hand wavings and other greetings for some two thousand miles through seven States.

A Day of Penalties—Superstition may not hold much sway among Glidden tourists, but nevertheless this was the thirteenth running day of the contest, and there were more serious derangements upon the road than ever before. The roughness of the highway, the presence of the semi-concealed washouts, and one or two difficult fords wrought havoc with the condition of contesting and non-contesting cars. In addition to the points which were brought out in the penalties, those at the finish were able to detect derangements which will be unearthed later.

One of the deep gulleys near the finish of the run was responsible for an accident to the big six-cylinder Thomas, driven by Gus Buse, Jr. The car was crossing the plains at nearly a 50-mile an hour clip when the ditch confronted the river. He set his brakes, but the car dropped into the gulch, and it was so racked that its motor sub-frame and a water connection were broken. It was seen that the engine was out of line, and so no attempt was made to bring it in under its own power. Buse decided to withdraw, thus incurring a penalty of 1,000 points in addition to the single point previously charged.

The two Maxwell cars, one in the touring car class with a previous perfect score, and the other, a roadster, were penalized for using new springs. The cars are two of the few in the tour without shock absorbers, and the great strain of the miserable roads proved too great. The touring car broke its left front spring yesterday, and replaced it this morning just after checking out. This penalty of 8.5 points, four of which were for labor, reduced the number of clean Gliddenites to five. The same number of points were given Goldthwaite, the Hower trophy Maxwell pilot.

Springs have been giving trouble in several quarters, and as a result of a long run on one spring before reaching Denver, the Glide this afternoon experienced further inconvenience. The spring seat on one side gave way, allowing the axle to shift, and necessitating a new one. Temporary repairs were made, and the car arrived late to-night.

The Mason two-cylinder car broke the tie rod in its steering gear and came in late to-night.

Jean Bemb, in his Chalmers-Detroit car, in the Detroit trophy class, also had a "thirteenth" happening. While filling with gasoline at the station before checking in this evening, a five-gallon can similar to those with which gasoline was being dealt out, was picked up and emptied into the tank. A few minutes later, after the car had been officially checked, the motor stopped, and it was discovered that the can was full of water, and belonged to another contestant. Chairman Hower allowed Bemb to drain his tank and fill with the real liquid without penalization. This ruling could hardly have been otherwise.

FOURTEENTH DAY—OAKLEY TO SALINA

(199.7 Miles)

SALINA, KAN., July 29—This was the hottest day of the tour, and at times it seemed as though Hades had something to do with the stifling atmosphere. The roads were fairly good, and even those which were ordinary proved exceptionally easy for even the lowest-powered cars. As one neared the day's destination the country improved, with the soil more fertile and occasional breaks from the monotonous plains. Corn grew higher and prosperity seemed more universal. When the day was done "Globe-Girdler" Glidden said that the weather reminded him of India and the scenery of the lowlands of Scotland.

Salina, with a population of about 13,000, has some 160 cars. It has an automobile club in process of vigorous growth, with W. W. Watson as president and George D. Adams as secretary. The four local garages had the greeting of the visitors in charge, and the one most appreciated thing was the inviting natatorium, where the dusty travelers hied with unanimous accord, there to splatter and soak for a couple of hours. These are the four concerns which engineered the welcoming: J. F. Ollinger and H. L. Center, selling Olds and Regal; the Natural Body Brace Company, Howard Rash, manager, handling the Maxwell; Central Kansas Auto Company, George Weisgerber, manager, selling the Great Smith, Ford, Overland, White and Brush; and the Salina Auto Company, F. B. Shellaberger, manager, selling Franklin and Buick.

Apparently the weather was too much for both Chairman Hower and Committeeman Stevens, for they gave up their places in the pace-making car to J. C. Kerrison and Howard Reynolds, two Bostonese newspaper men, who stuck it out in company with Mr. Glidden.

Five Penalizations Were Levied—Five cars felt the pencil of the official scorekeeper, though only one had a very large amount. The Glide touring car, driven by A. Y. Bartholomew, suffered most severely, and 276 points were added to those of previous days. The spring seat trouble on the front axle was remedied, and Mr. Bartholomew showed good sportsmanship by taking it, denying reports that he would withdraw. By the expenditure of a few cents he secured iron to replace the broken seats, and 25.7 points represented the labor. The work took so much time, however, that he was 215 minutes late, giving him his total of 276, and a grand total of 406.9.

The White steamer had to fix a fender, losing .4 of a point, .1 of which was for the wire and the remainder for the work. The only car in the Detroit class penalized was the Premier, which had 5 points given, 2.1 for material, in this case a rubber bumper and some wire. The bumper was used under a spring and the wire for fastening the mudpan, the total for material and labor of 5 points increasing the Premier's score to 5.8. The Jewel roadster lost 2.6 points, being the only Howerite penalized, for repairing a leaky gasoline feed pipe.

Two changes in penalties of previous days were announced this evening, that of the Maxwell roadster being 7.7 yesterday for its new spring, and the record of the Mason, which broke a piston pin bushing, being 330.2 points.

FIFTEENTH DAY—SALINA TO KANSAS CITY

(212.8 Miles)

Kansas City, Mo., July 30—The final day of the tour was a back-breaker, and the casual remark of Pathfinder Lewis at Minneapolis, that the wind-up would prove interesting to all, was brought to mind soon after the tough ride had begun. It had rained during the night and the precipitation had been sufficient to put the gumbo roads into fairly slippery condition, meaning the use of chains and a sliding crawl for some fifty miles. The clouds threatened more water, and until noon there were spasmodic showers which aided in making the roads more difficult.

Some four miles beyond Junction City was passed the hilltop monument which designates the geographical center of the United States. A half mile more and the largest cavalry fort in the country, Fort Riley, interested the tourists. Then a couple of miles further on and the first capitol of Kansas presented a relic of past glory, roofless and windowless, the abiding place of owls and rats. Scarcely three miles more and Ogden, the oldest town in the State, presented a picture of utter indifference to progress, for apparently the village belongs to the Rip Van Winkle class, and doesn't care much about it, either.

Manhattan, 71 miles from Salina, put on some metropolitan airs, including a betterment of the roads, which continued more or less to the conclusion.

Going through Topeka, the factory of the Great Smith car was passed, and of course there were enthusiastic greetings to the mud-splattered caravan. Near Kansas City the hills increased in length and height, with road surfaces rugged and stony. From Shawnee there was a macadam road into the city, though it supplied more dust and dirt than all the rest of the day combined.

The checking-in was in front of the Coates House, and there were sighs of great satisfaction as one after another the cars reported for the last time. "Jack" Williams, with his No. 109 Pierce, was first, though his No. 12 Midland, with E. O. Hayes driving, made what might have been a successful run for the honor had he not met with a most bothersome puncture in a ditch across the road, some thirty miles from the finish.

A single mark was listed in the Detroit trophy class. This was one of 20.3 to the Premier, driven by Waltman, for work upon springs and the replacement of one.

The Molines came in with a unique record in several ways, one of which was that there had not been a spark plug removed from any one of the trio during the entire trip.

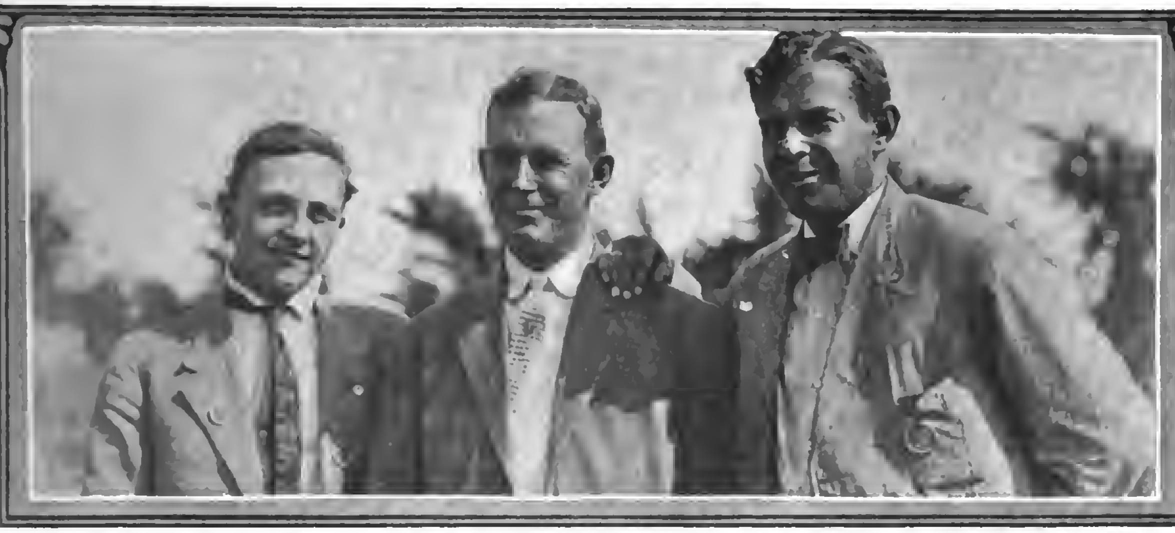
The two-cylinder Mason had the desirable goose egg for its final run.

Heavy Penalization Resulted—Nearly one-third of the competing cars were penalized as a result of this strenuous grind through the oozy mud of Kansas. Seven machines had to have time expended upon them in adjusting or repairing, and two of these in the Hower trophy ranks had had perfect records up to this time. The newcomer from the "Blue Grass" region, and the "Bluebird," from Detroit, were the unfortunates, the latter probably the more so because it was disqualified. The former is the Lexington, driven by John C. Moore, which was held ten minutes while its driver and mechanic each worked to replace a cotter pin that had dropped in the rear axle housing. The labor cost 2 points in scoring. The Chalmers received its very hard penalty for using a wheel secured from another Chalmers-Detroit to replace one broken. The rules explicitly covered the point.

In the same section there were three other penalties accorded to the Moline, driven by Gregory; the Maxwell, handled by Goldthwaite, and the Jewel, by Uhl. The Moline lost 29.5 points through the necessity of working upon a taper pin in the camshaft gear hub, the actual labor costing 13.3 points, material .2, and lateness at the finish 16 points. The Maxwell was held up to replace two spring clips, the penalty being 23.5 points, of which 21 was for lateness, 2 for labor and .5 for the material. The Jewel had a leak in its gasoline feed pipe from the auxiliary tank to the carbureter, and 5 points accrued through repairing it. Tape and soap were listed at .4, and the remainder as labor.

A single penalty was given in the Glidden class, that to the White steamer, of .7 of a point, .6 being for work in fastening a fender iron, and .1 for the wire.

On the Colorado Plains Numerous Morasses Were Partially Hidden by the Grass—Goldthwaite's Maxwell Found One of Them



Three Prize Winners of the Tour—Bemb (Detroit Prize); Winchester (Glidden Trophy); and Williams (Hower Cup)

OPINIONS VARIED AND INTERESTING ABOUT THE TOUR

F. B. Hower, Chairman of the Contest Board—"Of course, there will be another tour next year. Don't you believe that there won't be one. It always follows at this time that there must be a lot of talk about the event being the concluding one. The public may well invest in any car which came through this tour successfully with or without an absolutely perfect road score. This tour has been strenuous. The makers entered this tour primarily for publicity, but the experiences gained will prove of inestimable value in improving their product. The improvements in the cars of this tour will wipe out any little defects which may have shown, and when these improvements have been made the cars that are now competing will be ready for the proposed transcontinental contest of next year. I believe such a contest possible now, and in line with the desires of the makers. The question of season will have to be considered for the next tour, owing to the added time which will be required for its successful conduct."

Samuel B. Stevens, Member of the A. A. A. Contest Board—"The sixth annual tour has been a grand success, and I sincerely hope that there may be a transcontinental tour for 1910. The contestants in this tour did not fancy the idea at the beginning, but having won out with honors for all concerned in this event they now feel that the transcontinental is a possibility. Of course, the question of time enters into consideration. The proposed seventh annual could be carried through within a month I am quite sure. There would have to be two days lay-over each week to give time necessary for additions to the schedule in the event of bad weather. The real reason for the two-day stops at Minneapolis and Denver during this tour was possibly not generally understood. The extra days would have been utilized had the weather turned out bad. Regarding the rules for another year, I do not believe that they should be made easier at all, but I do believe that they should be made harder, if anything. The perfect car is not yet made, and may never be made, but we are fast reaching a point where confidence may be placed in any car. The troubles of the present trip have not been serious, and the makers who have had troubles, for the most part of the minor sort, will correct the defects for another year."

Charles J. Glidden, Donor of the Glidden Trophy—"Severe? Very severe hardly expresses it. The tour has been a hard test and a thorough test and a good one in every way. The showing for American cars has been immense, and I believe cars are now ready for the cross-country run. Early in the present tour many expressed the opinion that the longer tour would not be feasible, but after this 2,700-mile trip I believe that all think the time ripe for the greatest tour ever known, from the Pacific to the Atlantic. The transcontinental tour should precede any tour of Europe and will bring about a delay of the proposed tour of Scotland, Ireland and Wales, from Land's End to John O'Groat's. It may be possible that this will be in 1911, and again it may be better to tour the entire South before making the European trips proposed for several years."

Dai H. Lewis, Pathfinder of the Tour—"In my opinion, tours will go on year after year as long as there is a sale for automobiles. The great test of automobile construction is found on these tours, and the public and the makers want the tour. The present tour has been a grand test of construction and a great test of driving skill. The very fact that eight cars came through perfect in the road score and that so many came through with but slight losses due to minor defects is a great sign of the times. Cars are improving, as all will admit who took part or saw tours of days gone by. This tour was designed to bring cars through without a perfect score, and yet there are eight. It is wonderful, and it is evident that rules must be made ever more strict than has been the case in this tour. The idea of a transcontinental contest for next year is a good one, and if everything goes right I hope to be in this contest."

H. O. Smith, Chairman of the A. M. C. M. A.—"The 1909 Glidden has at least proven that the modern motor car can travel 2,700 miles at the rate of not less than one mile for every three minutes on the roads from Detroit to Kansas City, irrespective of weather conditions and without a repair or replacement or adjustment and without even tightening nut, bolt, or screw. The tour has furnished proof which should be worth to the manufacturer all the expense incurred and also supply information of inestimable value to dealer and to the individual purchaser."

W. H. VanDervoort, President of Moline Company—"I'm feeling pretty good, thank you, for we finished one car tie with the two Pierce cars for the Hower trophy, and had it not have been for a foreign substance that somehow crept into our gearbox we might have finished two cars. During our trip the Moline won honors by team work, for the cars always ran together unless in event of a puncture, and we had few of those, our Goodrich tires giving splendid service all through. The showing of the Moline this time has brought its reward, and I have already made three entries for the tour of next year, wherever it may go. I hope sincerely that next year's tour will be across the continent."

H. A. Croxton, President Jewel Motor Car Company—"We feel very well satisfied with the tour, and our showing is really a surprise to us, as our cars were both new when they started and had received almost no test. We hurried to get ready. We shall be in future tours. The idea of a transcontinental tour for next year is a good one and our entries are ready now when asked for."

Webb Jay, Driver of No. 1 Premier—"The public will not appreciate what the cars have gone through on this year's Glidden. The going was certainly hard and the rules strict. If the dealers and buyers only appreciated what information they could get by the showing of the cars they would be surer of getting their money's worth and a satisfactory car. The Glidden was certainly strict enough this year to cause the makers to stop and think whether they had any real doubts about their car. It is, of course, worth a lot to win, but I think if I were a manufacturer I would go in to find out weak points so that they could be corrected. The stayathome kind of manufacturers don't always know how much trouble their cars are giving and why every car they sell hurts them instead of selling more cars. Every fellow who buys a half baked, unproven car hurts the auto business, for he does not fail to tell his friends that he bought a cheap car and one which looked the most for the money. He is the one who shouts about the unreliability of automobiles and how expensive they are. He tells of the upkeep expenses. I believe in touring contests under rigid rules impartially enforced."

J. Machesky, No. 105 Chalmers-Detroit—"It was rough to strike that last day just when things were coming along so nicely, and tougher yet to lose out almost at the finish. I had to change wheels with Harry Bill and was disqualified, yet the wheel of Mr. Bill had come just as far as mine, and he merely took a little time, put mine into order, and then came on. I went into the last day settled firmly in my own mind that I had a perfect score, but changing wheels cost me a position."

H. N. Searles, No. 14 White—"This has been a severe test, a contest in which the cars have been forced through difficulties never before experienced. The A. A. A. planned a tour to bring forth no perfect scores, yet eight cars had perfect road scores and many more lost but a very few points. The present tour has been to me a very agreeable experience with the exception of the special train in which the men were so herded together as to make things disagreeable."

John C. Moore, No. 114 Lexington—"This was all new to me and I am unable to make comparisons, but the trip was tough and hard. The day's runs were long and the strain on a new car was enormous, yet the loss of points to us was but 3.8. I am satisfied to have finished successfully, and feel that I could not have done better, as many well known and well tested cars were in the competition. The trip has been a lesson to me."

E. O. Hayes, No. 12 Midland—"You can bet it was a hard trip, and I am satisfied to have finished, let alone get prize honors. The Midland is ready now to enter for a trip across America, and with comparatively few changes. The long hard days, the rough roads, the stiff schedule and the going into unknown dangers over the treacherous roads was an experience I shall never forget."

C. E. Goldthwaite, No. 107 Maxwell—"As a test for cars the tour proved all that was promised and a little more. All honors go to cars that pulled through with a perfect road score. I believe now, as I did not believe before, that it will be possible to shape up a tour under even stricter rules for San Francisco to New York. That will be the supreme test and I hope to be able to take part."

F. A. Trinkle, Driver No. 103 Brush—"Any car that came through to Kansas City along the route of the sixth tour is a car that anyone may safely purchase. This has been a hard run for the little Brush, but I am satisfied with this tour, for in spite of the terrible going, more so for the little than the big car in this instance, I was not last."

Walter A. Winchester, No. 9 Pierce—"The tour was an interesting run, and I am satisfied that the roads, the stiff schedules, and the long runs each day brought out the best cars in America. I am ready now to tackle anything in the driving line. Variety was the point of this tour, for every class of road was encountered."

Frank E. Wing, No. 4 Marmon—"The trip was hard to a man accustomed to New England roads and to tours of the past. Taken as a whole, the roads were the worst ever known for a long tour, yet the schedules were stiffer than ever known and the runs of each day longer. The strain upon the driver and the car was terrible."

John S. Williams, No. 108 Pierce—"I found nothing so very hard about the tour, and was satisfied to drive steadily and only as fast as possible to obtain a commanding position and be ready for trouble. Going out ahead is breaking road and hard on the car, yet my Pierce gave no trouble and my tires gave none."

"Teddy" Dey, No. 8 Pierce—"I've been on them all, and for wear and tear on car and man, this was the limit. It was tough, and that is true. Steady work, hour in and hour out, won. I am ready to take a Pierce-Arrow anywhere that may be desired, and across America is satisfactory to me."

A. Y. Bartholomew, No. 10 Glide—"I had a streak of bad luck in certain particulars that took a great deal of the pleasure out of the contest for me. Next year we will be prepared for a transcontinental or any other kind of a hard tour. My car ran splendidly."

Walter A. Woods, No. 51 American Simplex—"Care was necessary, but constant vigilance earned its rewards. I lost out through the plunge into that hole which held fifteen men and in which the Brush stood on its head."

HOW RAPID TRUCK CLIMBED PIKE'S PEAK

Kansas City, Mo., Aug. 1—Although the novelty of climbing Pike's Peak in an automobile has worn off since accomplished safely by a number of machines, no motor truck has ever attempted it before, and the Rapid truck in the tour justly earned great credit when the hard trip was successfully terminated. The start was made from the Antlers at daylight Monday morning, with T. P. Meyers in charge, Frank Grogan at the wheel, and Jim Curry as mechanic. Leaving promptly at 6:15, the eighteen-mile journey was nearly completed when darkness overtook the adventurous crew of the big machine, and they were obliged to stop and sleep on their arms, so to speak. Next morning, the top was plainly seen but three-quarters of a mile distant, this distance being completed easily by eight o'clock. The truck came down on its own power, finding this trip far easier than the upward one, which tested the nerve and skill of the driver to the limit. The Goodyear tires were badly cut up by the rocks but stood the journey and were used to the finish of the tour. It was certainly a strenuous test for a commercial car.

Rapid Truck Making Its Way Up Pike's Peak

HOW THE TOUR IMPRESSED ONE PASSENGER

BY W. W. BROWN, PRESIDENT AUTOMOBILE CLUB OF VERMONT.

I'm now arrived, thanks to the gods—
Through pathways rough and muddy,
Which surely shows that making roads
Is no' this people's study;
But though I'm no' wi' Scripture versed,
I'm sure the Bible says
That wicked sinners shall be damned
Who do not mend their ways.

THUS wrote "Bobbie" Burns after a drive over Scottish roads. I don't know whether the "sinners" who made these Western roads will be damned or not, but the roads themselves have been with all the fervency to be expected from men pounding nearly two hundred miles a day over them since July 12.

I have been asked for my impressions of the tour, from the vantage point of a passenger, and here they are, without fear or favor. I am in no way connected with the automobile business, nor the tour management. I paid all my own expenses and rode as a simple passenger, more or less accurately representing 125 pounds of sand. This was my first Glidden tour, and as a passenger I have had little to do except to keep my ears and eyes open to get all I could out of it, and I have thoroughly enjoyed every moment. I have met a lot of good fellows and been royally entertained.

W. W. Brown

The West is a great country, its people are cordial and open-hearted; everyone knows the reception we have had—it has been one grand ovation all along the line. But the country is all new and a bit raw, and with few exceptions the roads (outside of the large cities) beggar the name.

Any manufacturer who does not put a car in this yearly contest is missing something. I can see that the advertising for the cars in the run has been very valuable. The interest taken by thousands of future motorists during a three weeks' tour, covering seven great Western States, and passing through 336 cities and town, cannot fail to bear rich fruit. And they are buying cars. Little towns of three hundred people, with fifteen cars, is only one illustration of many I could give. Aside from the value of the advertising, it is the very best possible test that the manufacturer can get of the durability and efficiency of his car. Several builders of well-known makes and some factory superintendents and designers were driving their own cars in this tour.

One manufacturer and designer—and one of the brightest—told the writer personally that he had never been on one of these contests before, and that he would never miss another, as the experience was invaluable.

The drivers and their mechanicians, with few exceptions, were a conscientious, hard working lot of men—out to win; and the success or failure of any car depends largely on these men. I saw drivers who would smash up any car, no matter how well built, and others who would take most any car through safely. What knocks out many a car is the result of "speed mania" on the part of the driver. The time allowance is sufficient for reasonable driving. I know it creates a good impression on the public to come into controls among the first cars, but it militates against perfect scores. The observers—the most unobserving lot of men I ever saw—were all good fellows, but as observers there were many of them whom I should not want representing me and watching my competitors. It was the weakest point in the tour, and no one but the entrants themselves can be blamed.

I rode in the same car all but two days; the observers were changed every day. One said to me as we started: "Think I'll look over the rules; I haven't had a chance to read them yet." In questioning another as to how he came to be appointed, I found he was a friend of the entrant he represented and wanted to go on the trip for the fun of it. Another slept. I would give big money if I could sleep as that man did. I believe we could have put on a new spring and he still would have slumbered on.

Another said to me: "I use my own judgment; I don't follow the rules." Still another left the car with the driver and mechanic oiling up. They could have tightened up or made other little adjustments, though fortunately, or unfortunately, there was nothing to do on the machine.

Now don't imagine there were no competent observers. I know there were, but they should all be competent.

The tour was exceedingly well managed from start to finish; everything ran without friction, and when one considers the immense amount of detail involved, this is really remarkable. All moved like clockwork; there were no hitches, no delays. The route was well and carefully laid out and marked.

The contest committee hear observers' reports and pass judgment without knowing which car is in question. The chairman of this committee, the one dominant figure in the management, is a man with great executive ability, absolutely honest and fearless, doing at all times what, in his judgment, is best and right. A little more tact and consideration for others would, however, smooth his path a whole lot.

The gentlemen in charge of the hotel accommodations gave us the best which the several towns and cities afforded. They could not make bathrooms where baths there were none, nor change the hotel management; but we were as well taken care of everywhere as was possible.

The Pullman train of sleepers and dining cars were a decided success and reflected credit on the mind which conceived the idea. There were one or two disagreeable features incident to such an arangement during the hottest season in a hot country, but those who had been accustomed to travel and its consequent discomforts united in saying that the scheme was admirable.

There was a very general opinion among the men that favoritism was being shown a certain make of car. I know this to be false. It is true that in the early contests there may have been grounds for such a feeling, but there is no one connected with the present management who had anything to do with these earlier tours. But the car and the committee still get knocked. The car is a high-priced, well-designed, well-built car, with a well-organized crew, and is a logical winner under rules which compel low-powered, low-priced cars to compete on nearly even terms with cars of greater power and more expensive construction.

The rules under which this contest was run were formulated by a committee from the National Association of Automobile Manufacturers, working in joint session with the contest committee of the A. A. A.

The crews on the cars did a lot of talking about these rules, forgetting that they were formulated by representatives of the entrants themselves. Undoubtedly these rules are capable of betterment, but each car was entered with a full knowledge of the rules and "kicking" was a great waste of breath. However, it seems to be the opinion of the most experienced and thoughtful men that there was still too much laxity in the rules, and that penalties should be imposed for all adjustments, whether of

Teddy Day in No. 8 Pierce Following the Monotonous Prairie Road Through Eastern Colorado

carbureters or ignition system, or accessories, and that there should be a record kept of gasoline, oil and water consumption.

There is only one possible exception, and that is the adjustment of brakes, as a matter of safety, as drivers would run with brakes all gone rather than incur the penalties imposed for their adjustment.

The weaknesses developed in the contesting cars by this trip will be shown by the reports of the contest and technical committees. To an onlooker there appeared to be very little motor

A Reminder of Early Fighting Days in "Bloody" Kansas

trouble, penalizations being mostly for broken springs and retightening and replacing loose or broken accessories, fenders, feed pipes, etc.

The Press:

Drink to the press.
But do not press to drink
The gentlemen whose task is slinging ink—
They're usually men of sober views,
And never should be full—of aught but news.

We had about twenty-five along, and some were "slinging ink" and some mud, and some were sometimes full of news, and

Some of the Contestants "Talking It Over"

some were sometimes full of —— If you can think of any suitable rhyme fill it in. The gentlemen of the press were like any other group of mortals, all kinds, but mostly good fellows.

The representatives of the strictly automobile publications have done some "classy" work, and should be proud of it. But oh, you press men—who write stuff to fill space in the dailies, why cannot you give us something near the facts? Of course, we dont expect too much, but just get *near*, and couldn't you cut out the slush? This isn't my game, and I may not know what I am talking about, and, perhaps, the great benighted public wants that kind of "dope"; at any rate there was a lot of appallingly inaccurate news dealt out every day about this tour.

And now before I go back to the hardware store with my hammer, just one word about the "grumblers." Fault-finding, as a rule, is a pretty good proof of lack of knowledge or experience. The man who lives in luxury at home, or who is widely traveled, learns to accept conditions as he finds them on such a trip as this and make the best of everything. The strain of the long, gruelling ride began to tell on the nerves of the men, and toward the end of the run there was a good deal of "kicking" about things that would not have ruffled them at the start. You can't drive two hundred miles a day, over rough roads, and then be out with a "Floozy" all night, or attempt to fill a contract to make a dry town out of a wet one and then get up at 5 a. m. and find the steak tender and the service prompt.

The cup donor, Mr. Glidden, who has been on every tour, was with us every day, a most genial gentleman, meeting old acquaintances and making new ones everywhere, always thoughtful and courteous, making his speeches short and his hand-clasp long—a prince of good fellows!

And now it is all over and up to the technical committee (whom may Heaven protect), and the drivers, mechanics and observers are up in the convention hall, where the battered, "throbbing monsters"—see daily papers—have ceased to throb and are receiving bi-manual examinations by the two gentlemen constituting the committee, preparatory to being operated upon for the complete restoration of their mechanical health, while I am sitting, this scorching Kansas afternoon, in my hotel bedroom with my Apollo-like figure decorated with a fountain pen and a briar pipe, pushing the one and pulling the other and computing the fabulous price I would willingly pay for a long draught of cold, clear Vermont spring water.

Kansas City, Mo.

Hotel Accommodations Handled by an Expert—One of the hardest jobs in connection with the big tour is the apportioning of sleeping accommodations. The man who handled the task this time was Glenn A. Fargo, of the Hotel Lafayette, Buffalo, and while it is true that he, like all others who preceded him on the job, had some kickers, it is a fact that his work gave greater satisfaction than has ever been experienced before on the tour. He preceded the tourists as long as they were booked for regular hotels, and from Fort Dodge to Kansas City he was major domo of the moving Pullman hostelry.

NOTED AT THE TOUR'S CONCLUSION

Why Hower Used the Train—It seems that Chairman Hower is one of those who suffer much from hay-fever, and the dust of the road aggravated the complaint excessively. Hence the chairman had a very good excuse for his frequent utilization of the train, and thus had the opportunity of enjoying his private car a la Harriman.

Detroit Trophy Winner Used Diamonds—Diamond tires are represented in the winner's list by the Chalmers-Detroit car which captured the Detroit trophy for toy tonneau cars. There were twelve cars to start with Diamond equipment, one of them with solids, but for reasons which had nothing to do with tires, three dropped from the ranks en route. Nine cars finished with the Diamonds, two of them with perfect scores.

Tour's Physician Was an Observer—This was the first national tour in recent years in which there has not been a regularly appointed surgeon riding behind the contestants. The medical honors of the 1909 tour belong to Dr. T. F. Seymour of Mishawaka, Ind., who rode as the observer from the American Simplex interests. His compact medical case was called upon many times by the tourists en route with successful results.

Goodrich Tires on Glidden and Hower Winners—From the point of tire equipment the Goodrich Company was again successful in the winning of the Glidden end, for the third time, the Hower trophy. In this year's contest twelve cars started with Goodrich tires and every one of them finished, six having perfect scores. On the dozen cars there were but 17 punctures among 48 tires, and the long hard days of driving over rough roads made the trip a thorough test upon them.

Samples of Kansas Wheat—Soon after crossing into Kansas, one enterprising wheat-grower, J. E. Fitzgerald, of Weskan, saw to it that some excellent samples of Red Norway spring wheat were tossed into the passing cars. It is not positively known, but it is among the possibilities that some of the 1909 Gliddenites may later be found located on Kansas farms, for Mr. Fitzgerald stated that the samples donated were from seed sown in the last week of April, which meant a great yield for three months' growing.

"The Transcontinental Tour is possible now," said George Schuster, winner of the Around-the-World race, "for cars have passed through hardly more in this tour than they will be called upon to go through in a trip from coast to coast. It is evident that the rules will have to be made even more strict, and I believe that cars should never finish with a perfect road score after breaking parts on the road that are not repaired. For instance, one car broke a spring, and drove through without repairs, securing a perfect road score. Road breakages when not repaired should bring a penalty immediately and put that car out of the perfect list at once."

The Steamer Which Used Kerosene—A feature watched with special interest was that the White Steamer used kerosene, or "coal oil," instead of gasoline. The new fuel worked splendidly throughout the long journey, and claims made in its behalf were well proven. First of all, as regards cheapness, the White driver secured kerosene all along the route from 6 cents to 10 cents cheaper per gallon than was paid for gasoline. Secondly, the new fuel was handled without any precautions, and it was not unusual to see kerosene being poured into the fuel tank while the crew of the car and an interested crowd stood by with lighted cigars and cigarettes. At the finish of the tour the White was the only car permitted to enter Convention Hall, where the technical examination took place, without draining its fuel tank. Thirdly, the new fuel proved to be absolutely without smoke or smell. Fourthly, kerosene could be purchased at whatever part of the route was most convenient, and not once during the trip through the ten States of the Middle West was there found a grocery store where kerosene was not readily and cheaply obtainable. Finally, the amount of fuel used on the trip showed that kerosene is at least fifteen per cent. more efficient, gallon for gallon, than gasoline. The car in other respects made a most creditable showing. The only adjustments or repairs charged against the car were tightening a lubricator pipe and wiring a damaged mudguard. These penalties were not inflicted until more than 2,000 miles had been completed with an absolutely perfect score.

1909'S TOUR AND 1910'S TOUR

Never before, here or abroad, were automobiles subjected to such a severe, prolonged, and diversified test as that necessitated in the A. A. A. endurance tour which came to its conclusion Friday last at Kansas City after fifteen days' running. Any car surviving this arduous reliability examination, with or without excessive penalization, need have no fear of meeting the requirements of owners who demand vehicles of no uncertain manufacture, capable of withstanding unusual and unexpected strains, and at the same time possessing speed in quantity sufficient to satisfy any reasonable man who does not use the public highway as a race course.

The concerns which openly proved the worth of their products in the tour just ended will profit commensurably by what their cars accomplished, to say nothing of the great cumulative value which follows as a sequence of the multiplied repetition of the names in print. Unconsciously, the public associates almost in a class by themselves, those cars which participate in national events.

But the 1909 tour had a disappointing entry, and reasons therefor are not all agreed. Through experience one learns—and this sixth tour of the governing organization will enable a better reliability to be conducted another year—if one is wanted. If a big endurance tour is still an asset to the industry—and we are inclined so to believe—it deserves a more unanimous support from the trade than was accorded this year. To secure this endorsement it would appear that the thing must be gone at in an entirely different manner.

Let us start out on the supposition that twenty makers believe in a national tour of some kind; exactly what, would have to be settled at a conference called for the purpose. It is decided that the industry can well afford to support such an event, and that all engaged will have a chance to benefit in a more or less degree, it being taken for granted that winners will profit the most from a publicity consideration.

It being the unanimous sentiment of the twenty that a tour is wanted, the twenty then and there guarantee one or more enteries, and furthermore deposit one-half of the entry fee. This would insure a representative field and add substantially to the benefits accruing.

Then would come the drafting of the rules, and such a drafting as would leave nothing to the discretion of the contest committee except the enforcement of the plainly worded regulations;—no handing to contestants penalties decided upon at the eleventh hour.

And right here it is urged that the tour be divided into two distinct departments, one having to do with the business direction of the event, and the other to be concerned solely with the competitive feature. One man should not dictate the entire situation, no matter how well he might be qualified for the position, for in this American republic there is an inbred dislike to monarchial control. It does not always follow that a good business man is equally successful in looking after details of a technical nature, which in their entirety should be left to a competent committee, without any possibility of interference from any other source. This is a vital point in connection with another tour.

It is a foregone conclusion that microscopic examination at the end of a tour can be utilized in bringing about the selection of so-called final winners. But some method should be evolved whereby first-class certificates should be issued to all contestants finishing within a maximum loss of points, say not more than one hundred, for the entire tour. In other words, this would mean a physical catechising of the cars such as would require a degree of reliability sufficient to satisfy even the most exacting buyer of an automobile.

In any sort of an examination very few ever pass at 100 per cent, and consequently it is logical that machinery, in its performance, should have the same kind of a chance as man, and all the glory of the tour should not go to the car which perhaps may have been a little more fortunate than the others in escaping ruts and stones that bestrew the path.

Coincident with reliability, the general public is beginning to associate economy. Next year's run should include exact information as to consumption of gasoline and oil, and, in order to make the figures more understandable, it would be well to have the contest an exact distance, say 5,000 miles. Thus the cost per mile per passenger, and all sorts of newsy statistics, could be extracted from the results of the tour.

But, first of all, let the manufacturers themselves decide as to whether they want a tour, and until then the A. A. A. should decline to go forward until it is evident that its services are desired. At the same time, no one questions but that the enforcement of the rules, after made, should rest entirely with the contest committee of a disinterested organization.

Characteristics of Piston Rings

Chapter IX

LEAKAGE by the pistons in cylinders of motors is one of the difficulties which is prone to manifest itself as the product of wear in regular service after a time, and even in new motors unless the work is most carefully done. Compression, which makes for power next to a balanced fuel mixture more than any other one point, will be lost if the piston rings are not tight, owing to the clearance which must be given to pistons, in view of the great heat raise and temperature variations as well.

To a vast extent the life of motors in actual service is coupled to profuse lubrication, using suitable grades of lubricant for the purpose, but the piston rings must be properly made, of proper materials, and nicely fitted as well, in order to make care and lubrication worth while. Trouble from inferior piston rings will be the most conspicuous when the compression is high and when the speed is low. This follows, since if the compression is high the explosion pressure will be much accentuated, and the higher the pressure the greater will be the pressure leak, heat change, difficulty in lubricating, and wear on the rings. If the speed is low, the time for the compressed charge to leak by will be prolonged, and, incidentally, if the stroke to bore is relatively long, the time will be prolonged on this account.

From what has been said, then, it is plain that the piston ring question becomes of the greatest importance in connection with long stroke, high compression, relatively slow speed motors, and granting that this type of motor will afford an increased energy output under refined conditions; even so, if the work is indifferently done the results will be disappointing.

Success Depends Upon Quality of Material—While rings are made of cast gray iron, even so, the quality must be of the finest. The castings from which the rings are turned may be in the form of a tube long enough to allow of turning out enough rings for a motor, and in a "six," if the rings are 5-16 inch face, using four to the piston, considering the material wasted in cutting off, the cast tube will have to be at least eight inches long, to which must be added the "accommodation" pieces, by means of which the tube is held in the jaws of the "chuck" of the lathe. Other length will be in proportion.

If the rings are to be 1-4-inch radial thickness when finished, the radial thickness of the tube must be more by an amount sufficient to assure that the rings will finish up. It is desirable to limit finish, since the superior metal will be found close to the surface of the casting. If 1-16 inch is allowed for finish on the exterior as well as interior of the cast cylinder, and if the walls are of uniform thickness all over, there should be little trouble in turning out good rings, provided the castings are poured from a good cupola charge, at the right time, at the instance of a "gaffer" of skill.

Rings Are Turned to a Greater Diameter—Since the finished rings must be of greater diameter than the bore of the cylinder by an amount equal to the difference in diameter of the bore and the piston, plus the amount of spring required in the rings to cause them to press against the cylinder walls firmly, they must be finished to a greater diameter, after parting, when the slip joint is made. This is done in a clamping chuck, and the same chuck serves for grinding the surfaces of the rings in the finishing process.

Extract from Vol. 1., Part II., Chapter IX., of a set of books, in preparation, by Thos. J. Fay, covering all phases of automobiling, from the point of view of designers, constructors and in actual service.

Grinding Is Necessary if Results Are to Be Good—Rings are usually ground on their faces by means of a special tool in which a magnetic chuck is the conspicuous feature. It would be very difficult to hold the lighter types of piston rings in any other form of chucking device, and even in the hands of machinists of great skill the rings would probably deform as a result of jaw chucking. The magnetic chuck alters this, and all that remains is to grind the surface of the rings after they are "parted" from the cylinder from which they are being made, and at the slip joint. Considering this plan, the rings are first reduced to near diameter in and outside (allowing about 0.010 inch for grinding) in the wroughing process.

Grinding is of the greatest advantage, especially in connection with cast iron, which is not of uniform texture, owing to the presence of a certain amount of white iron, which is very hard,

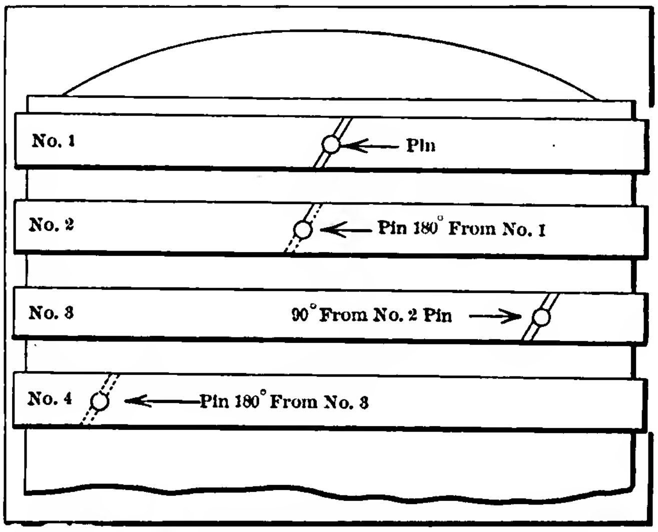

Fig. 1—Rings are placed to break joints and prevent direct leakage

and the effect of these hard zones, since the tool is prone to back off as it enters them. This is not, under ordinary conditions, a matter of great moment, but in piston ring work, since the rings have to be accurately made if they are to be of the greatest utility, grinding is the best practice.

Rings Are Pinned to Break Joints—Referring to Fig. 1, it will be observed that the four rings are so placed on the piston, in the ring groove, that none of the ring joints is in the same vertical plane, nor is the distance between any two joints less than 90 degrees. The joints of the second and fourth rings are shown in dotted lines, and in the first and third rings the pins show at the joint sufficiently plain to indicate the manner of profiling the rings in order to accommodate the pins.

There is some chance of the pins drifting out if they are not a drive fit, and that this work should be done by a fitter of more than ordinary skill is indicated by the amount of damage that a pin, if it drifts out, will do to the bore of the cylinder. If the dowel pins are made with two diameters, as shown at F, Fig. 5, they will be locked in place, since the shoulder on the pin, if the pin starts, will intercept the ring and be prevented from drifting further. Dowel pins are usually about 1-8 inch in diameter, made of Bessemer rod, and carefully hand fitted, in

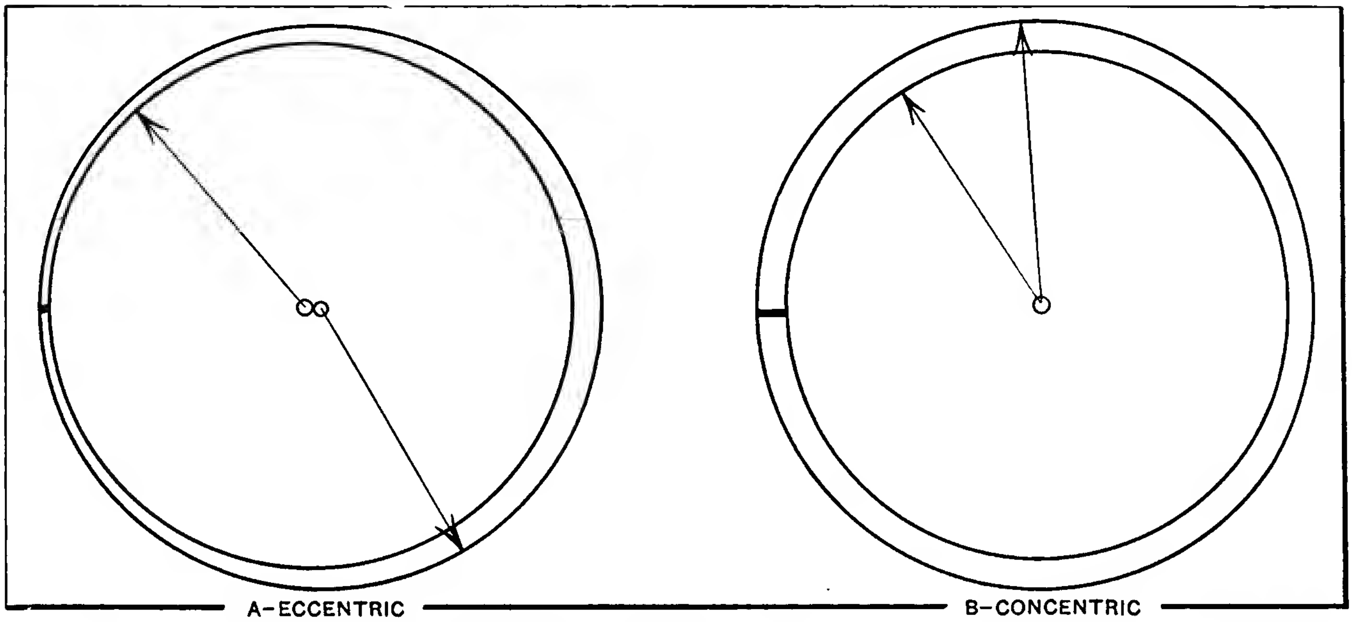

Fig. 2—Eccentric rings are designed to afford an even pressure, and concentric rings are peened to afford the same results

order to render them so tight that they will not start, even though they are fitted with a shoulder for locking purposes.

The mere fact that dowel pins are used at the joints constitutes no good reason for carelessness in fitting the rings at the joints; they will leak a little, perhaps, when the work is very well done, and any such leak will detract from the compression, hence from the power of the motor.

Spring Tension Must Be Equal All Around—The difference between rings, as used for packing, in motors for automobile work and motors in general lies in the use of rings of a small sectional area, carefully fitted. Since the piston speed of motors of the automobile type is even above 1,000 feet per minute, under full power conditions, it follows that the amount of power which would be wasted were the rings to press heavily far exceeds the allowable.

A very fair allowance for the power consumed by rings is on a basis of one horsepower per inch of ring depth, on the piston, at 1,000 feet per minute, considering a six-inch bore, which allows for a ring pressure of ten pounds per square inch against the cylinder walls. The several investigators who have given the matter attention report losses even as high as one and one-quarter horsepower per ring, which must show excessive pressure and inferior fitting when the loss is so great.

Some rings are made eccentric, as shown in A, Fig. 2, and the amount of eccentricity differs as between the several examples over broad ranges. The idea is to afford equality of pressure without having to do much fitting, and that the plan has considerable merit is generally believed. As a general proposition the difference in ring thickness due to eccentricity is in the ratio of 1:2, and since many motors are fitted as depicted in B, Fig 2, with no difference in thickness of the rings, it follows that the only danger lies in having the rings thin out too much.

When the rings are concentric, as shown in B, Fig. 2, it is the practice to "peen" them in order to lay the fiber, relieve the internal strains, or so distribute the ability of the metal as to render it capable of pressing out equally at all points in the diameter. For this purpose a peen hammer, in the hands of a man of skill, is used to peen the rings by striking against the inner surfaces at equi-distant points. The blow must be carefully regulated and the backing must be rigid, in order not to fracture the rings. The process is one of compression, and by bruising the metal at equi-distant points it may be shaped in or out to suit the occasion, and the amount of pressure the ring is to exert may be regulated by this process.

Joints Are Made in Divers Ways—Referring to Fig. 3, A represents a joint which finds a place in many makes of motors, and when the surfaces are parallel and closed, as shown at B, when the piston is in place and "hot," it works very well. The overlap joint, shown open at C and closed at D, is probably better, since the parallel surfaces of the joint will help to main-

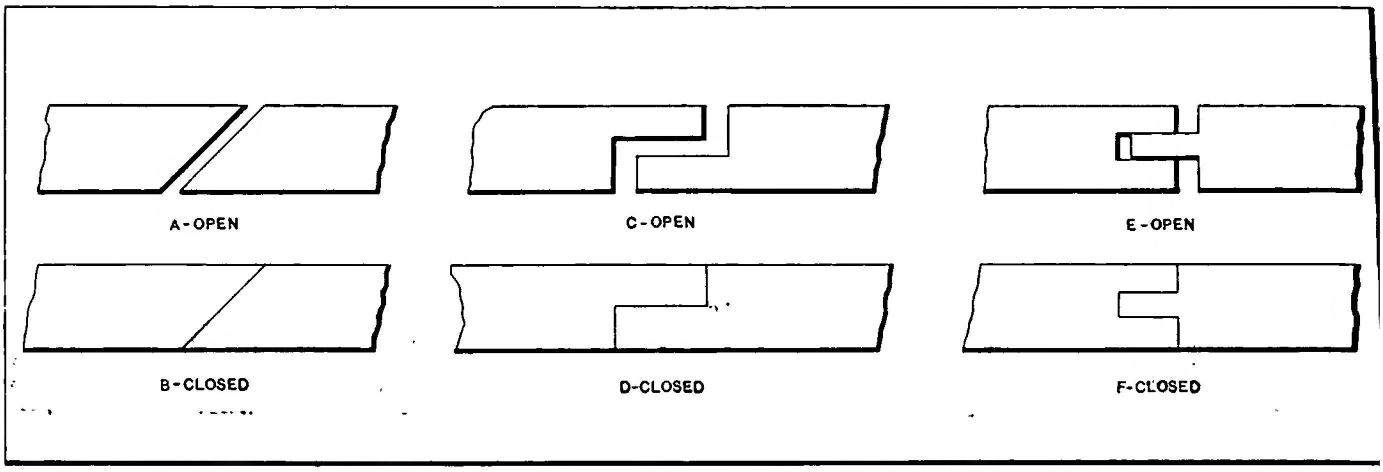

Fig. 3—Slip-joints of rings are made in divers forms, all with the idea of defeating leakage at joints as well as around the bore

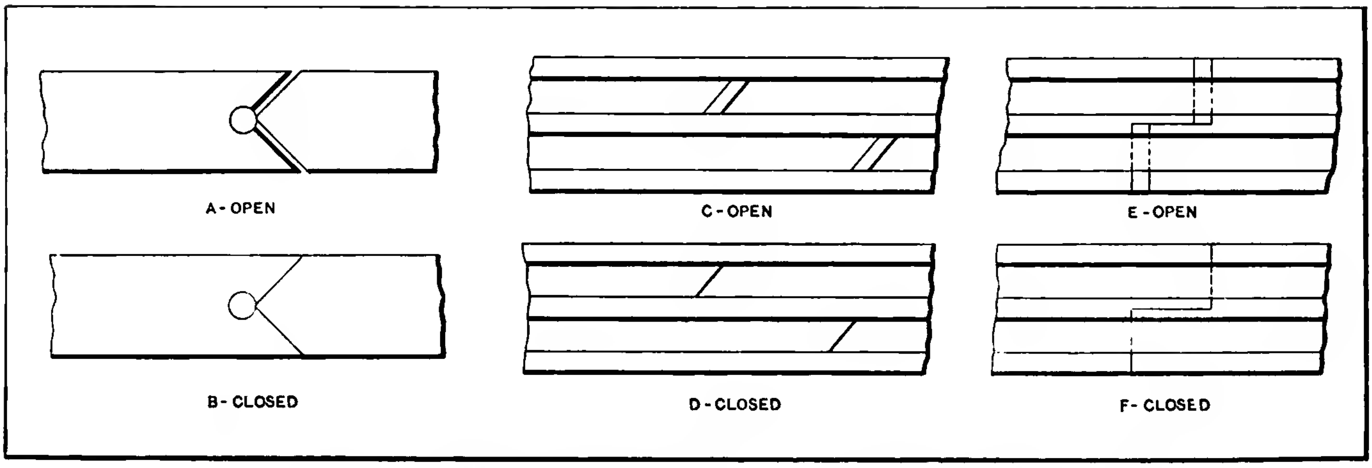

Fig. 4—Other forms of ring-joints, some of which are much in vogue, and others but little used

tain tightness, without having to figure upon the difference between cold and hot conditions, which is a difficult matter. This joint requires good fitting, or the surfaces at the joint will fail to be tight, but the joint, E, in the form of a tongue, is even more difficult to make, and it offers no advantage over the one previously mentioned, for the reason that there is but one set of surfaces in contact when the piston is traveling in one direction; this joint is shown closed at F.

Fig. 4 represents another series of joints, and A represents a modification of A, Fig. 3, which modification is without special merit, although it is probable that this joint will work very well when the fitting is well executed. A joint which is used in compressed air work more than in motors is shown at C, D, E and F, Fig. 4, and it is really a nest of rings, with one large ring supporting two smaller ones. The two smaller rings are shown open at A and closed at B; it will be observed that they do not have their joints in the same vertical plane, and the joints should be spaced at least 90 degrees from each other around the piston. At E the joint of the master ring is shown in the open position and closed at F. This joint is designed to come at a point remote from the joints of the nest of enclosed rings. In this way any leakage at any one joint will be headed off, since it will have to pass around the piston at least 90 degrees before it will intercept another joint. Time is a great factor in this class of work, since, if the leakage is impeded, the piston will perform its functions ere the leakage will diminish the power to a material extent.

Bearing Surfaces Must Be Parallel and Close—The rings, to be tight, must press against the walls of the ring grooves on the top and bottom sides alternately, depending upon the direction of travel of the piston. For tightness all depends upon the quality of surfaces and parallelism. The rings must not press against the radial bottom of the groove, and in order to prevent this the groove is made deeper than the thickness of the rings in the radial plane. The difference may be even 1-64 inch, and it is also true that the rings will not press against the top and bottom faces of the grooves simultaneously, since they must be free to move, in order that they will accommodate themselves to the differences in diameter of the cylinder and to the lateral play of the piston, which may not be without clearance.

Fig. 5 depicts the relations, and clearance is shown back of the rings. When the piston is in place in the cylinder the rings protrude a few thousandths of an inch, depending upon diameter and temperature, but when the piston is out of the cylinder the rings protrude considerably, which is an indication of the spring tension of the rings against the walls of the cylinder. If the rings do not protrude when the piston is out of the cylinder it is a sure sign that they will fail to perform their allotted functions when they are in place. In the process of peening it is the aim to make this difference such that the rings will press evenly all around against the walls of the cylinder when the piston is in place, but it is not desired to have the pressure above, say, 10 pounds per square inch. If, in peening, the rings are damaged even to a slight extent, it is necessary to scrape them to a true bearing, and in some shops they are scraped (even if the grinding process is well done), besides grinding. That a skilled workman will be able to make a good fit by scraping is proven by the good performance of many motors in which hand fitting is resorted to, and despite the use of special machinery in the process, it is proper to consider a certain amount of hand work. Damage, more than advantage, will follow, if the workman who is awarded the task of scraping is lacking in skill in the process. Even if the artificer is skilled, the facilities must be in keeping with the exacting nature of the work to be done, in order that the results will be up to a fitting standard.

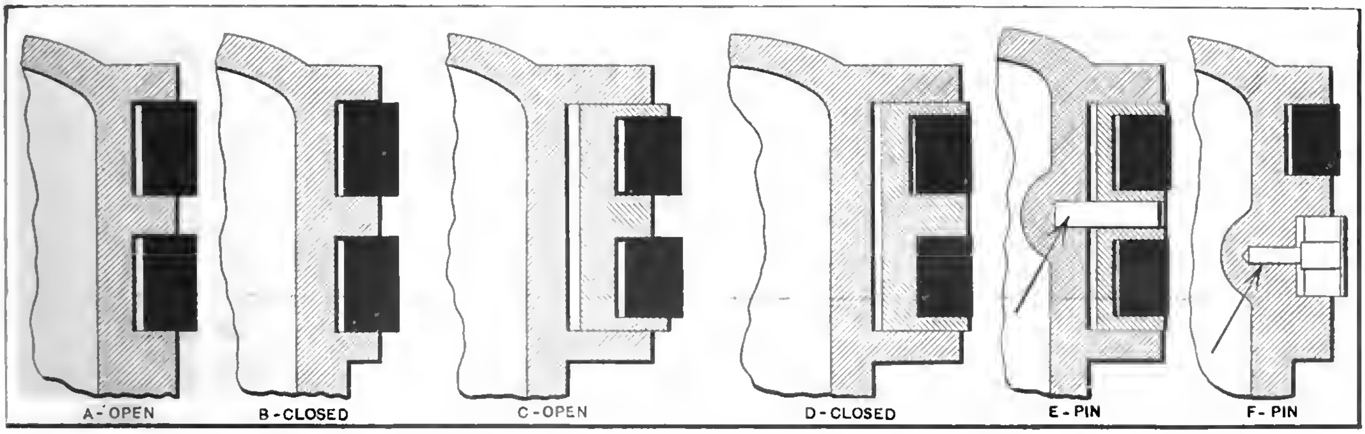

Fig. 5—Sections of pistons showing clearance back of rings and means for fastening dowel pins in place

In Fig. 5, A and B depict individual rings, of which at least three are used on each piston, and at E a dowel pin is indicated, which has the facility of preventing the ring from floating around so that joints will ultimately come in the same vertical plane. C, D and E show the nesting system of rings, indicating clearance behind the master, as well as behind the nested rings. E depicts a dowel pin for the master ring, and it will be understood that dowel pins are used for the nested rings at proper points; they fasten into the metal of the master ring.

Piston Rings Must Be Carefully Handled—In the process of fitting, if the artisan is not dexterous, they will be "sprung" out of shape, and when in place will fail to conform to the curve of the bore of the cylinder; if the rings are gently pressed over a set of thin, wide, flat blades, and thus sprung to a sufficient diameter, uniformly all around the circle, they will slip over the piston and into the slot without being damaged.

If they are fitted by a man of great skill and a certain amount of scraping is done to render them fit, they will have to be removed and replaced a number of times, and the chances of doing damage are very great; the process, as above indicated, will abort such tendencies to a marked degree.

A close scrutiny of the finished rings is essential to good success, and the inspection department, in the shops which turn out quality cars, are fitted out with facilities such as will enable the inspector to arrive at exact conclusions. A microscopic examination of the materials is also of value, and conclusions may be reached as the result of comparison, using a specimen, of known quality to go by.

CONNECTING RODS MUST BE LIGHT AND STRONG

BETWEEN the crankshaft and the piston for each cylinder of a motor, it is necessary to employ a connecting rod, and in view of the inertia effect on the mass, following rotation, and reversal of direction of motion, it is necessary to design the parts in such a way as to limit weight, or else the stresses in the section of the crankshaft will be such as to limit the speed, hence power, of the motor.

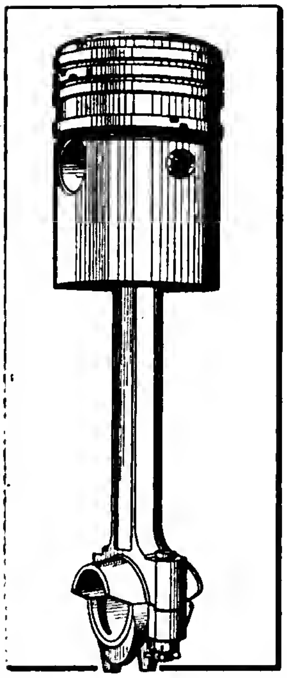

Fig. 1—Conventional design of connecting rod and relating parts in place

Fig. 1, depicts a design of connecting rod, of the I section, with every evidence of lightness, and strength at all points conforming to the requirements. The crankpin end, which is most likely to influence the results, is made light by using two bolts, and cutting away the cap, on which pressure is relatively light. At a point, 6-10 up from the center of the crankshaft bearing, the section with relating proportions, as shown in Fig. 2, and the taper of the connecting rod is on a basis of 3:2 from the crankshaft end.

In many examples of good connecting rods the cap is bolted on by means of four bolts, rather than two, as shown, and the cap is extended out in replica of the half of the bearing on the connecting rod.

Connecting Rods are Subjected to Various Influences—Compression, tension and flexure will be present in these members, in magnitude, depending upon the following:

(A) Compression due to the pressure of the gas, in compression, and on the power stroke.

(B) Tension, due to inertia.

(C) Flexure, primarily in view of the angularity of the connecting rod, and again, in a kinetic sense.

Compression, due to gas pressure, will decrease as the speed of the motor is increased, due to the restricted flow of gas at the higher speed, which is proven by falling torque with increasing speed as shown by a torque test.

Tension will decrease as the angularity is increased, which is a matter of the use of shorter connecting rods, considering a given stroke; it will also decrease as the weight of the members is reduced. It will increase with increasing speed. Tension will decrease with the shortening of the connecting rod, for a given stroke, due to the influence of side pressure, as well as on account of the reduction of the weight which naturally follows if the length is very much reduced.

Flexure will increase as the connecting rod is shortened, for two reasons: *a*, in view of increased angularity, and *b*, following augmented side pressure. Ability of the connecting rod to withstand flexure increases as the rod is shortened, so that a compensation is introduced by the very method that brings on the tendencies.

Rational Column Formula, Involving Least Radius Gyration—If the material is drop-forged mild steel of a good selection, the constants for wrought iron will serve very well, and the formula may be written thus:

Let,

p = ultimate strength per square inch.

l = length of connecting rod in inches.

r = least radius of gyration for the section.

when,

$$p = \frac{40{,}000}{1 + \frac{1}{20{,}000}\left(\frac{l}{r}\right)^2}$$

Since the above formula solves for the ultimate strength it is necessary to consider a factor of safety, and in view of the ills of excess weight, this factor should be limited, which may be done if the material used is from a careful selection. A factor of safety of 4 would seem to be adequate.

The Use of Bronze Is Deplored—Under no circumstances can the use of bronze for connecting rods be justified; it is high priced; of limited kinetic ability; likely to hold hidden flaws, and limited in ability from the point of eccentric columns. Die frogings of steel are not high priced, they may be of great strength, and under proper conditions the machining process is a simple operation, attended by great accuracy, and with full assurance that "wasters" will be reduced to an infinitisimal percentage. The formulae, as given, may not, with safety, be used in connection with bronze.

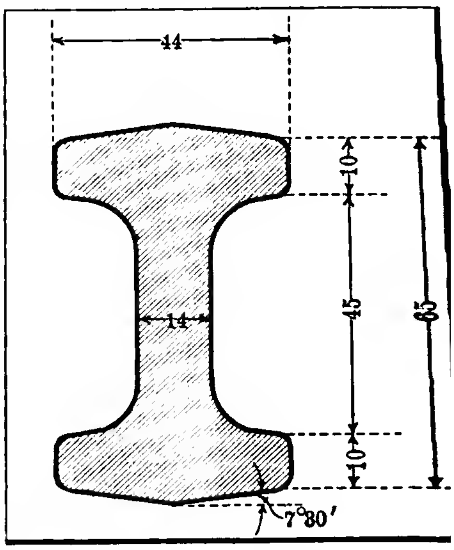

Fig. 2—Economical form of I section as used in connecting rod work

SCIENCE OF JUMP SPARK COILS*

By J. A. Williams

AS used in gasoline engine ignition, the jump spark coil occupies rather a neglected place in the art. The reason for this lies in the fact that because it is apparently a very simple piece of apparatus, and the principles under which it operates are supposed to be so well known, comparatively little electrical engineering thought or effort has been applied to its development along the best lines.

It is generally supposed that a jump spark coil consists of a core of soft iron wires, surrounded by a primary winding of comparatively few turns, which is surrounded by a secondary winding of relatively a great number of turns, a vibrator for interrupting its circuit, and a condenser for absorbing the extra current of induction, as it is called, or the spark at the points. This definition seems to pretty thoroughly cover the average man's idea of a jump-spark coil.

The jump-spark coil when properly designed and constructed, and used in connection with the proper system of jump-spark ignition, will do even more for stationary engines than it has for the automobile or motor boat.

The difficulties to be overcome in automobile ignition are relatively easy, as compared with the conditions to be met with in stationary engines. Practically all automobiles have reasonably low compression and use mixtures quite rich in gasoline vapor; for economy of fuel in the automobile art has not been considered a necessary factor, and it has been partly sacrificed in order to obtain greater reliability.

In the modern engine, compressions have been carried to the very limit permissible with the kind of fuel used, with the end in view of getting the greatest possible fuel economy throughout all the various ranges of load.

The iron wire core consists of a bundle of soft iron wires and occupies axially the central position in a spark coil. The iron wire used should be extremely soft, possess great magnetic conductivity, and the property of instantaneous and complete demagnetization. The function of the iron wire core is to receive from the primary winding and store up in the form of magnetic energy, the electrical energy that is applied to primary winding.

The primary winding consists of a few turns of heavy, well-insulated copper wire of high conductivity. In the usual coil it consists of from 200 to 300 turns. The function of the primary winding is to receive the battery or magneto current and circulate it around the iron wire core, so as to charge it with magnetic lines of force. Furthermore, it has an additional function in acting as the primary winding of a transformer when operating under the condenser discharge and producing a secondary spark in the secondary winding.

Very Many Turns to the Secondary—The secondary winding consists of a great many thousand turns of very fine silk insulated copper wire and surrounds the primary winding. The function of the secondary winding is purely that of a transformer, as it multiplies the voltage of the primary winding and at the same time reduces the amperage in a ratio entirely dependent upon the number of its turns, as compared to the number of turns in the primary. For instance, if there are one hundred times as many turns in the secondary as there are turns in the primary, then there will be one hundred times as many volts in the secondary as the condenser discharge delivers to the primary winding and conversely one hundred times less amperage in the secondary winding than there are amperes passing through the primary, due to the condenser discharge.

The vibrator of a spark coil consists of a stationary electrode which is tipped with a platino-iridium point and a movable or vibratory electrode which consists of an iron wire core and is held by spring tension away from the iron wire core and keeps its own platino-iridium contact in firm contact with the platino-iridium point of its stationary member. The function of the vibrator is purely that of a circuit breaker. It simply breaks or interrupts the primary current and stops the flow of primary current when the iron wire core has been charged sufficiently strong with magnetism to produce a satisfactory secondary spark.

The condenser consists of a number of alternate layers of tin foil and mica, or tin foil and properly prepared paper. So many of its sheets are positive, are connected together, and lead to one electrode of the vibrator. An equal number of its sheets are negative, connected together, and lead to the other electrode, but are insulated from the positive sheets by means of mica or paper, but usually the former.

Functions of a Condenser—The function of the condenser is not, as commonly supposed, merely to stop the sparking at the platino-iridium points when they interrupt the current. True, it performs this function, but merely incidentally. Its true function is to receive the kick of the coil, thus receiving and storing the impulses of electricity generated in the primary winding by the rapid demagnetization of the iron wire core upon interruption of the primary current, then instantly surge or throw this increased amount of electrical energy through the primary winding.

This is the principle that all dynamos or mechanical generators of current operate on. It isn't the mere fact of possessing lines of force threaded through the axis of the winding that creates a current, but it is the rate of change that produces current. An increase in number of the lines of force will produce an increase of voltage or current in the opposite direction. We therefore see that the rapid abstraction or accretion of lines of force will set up a powerful electromotive force or voltage within the primary winding. This electromotive force charges the condenser with a heavy current of strong voltage. The condenser in turn reacts in the opposite direction and sends a strong current through the primary winding, which in turn demagnetizes the iron wire core. It in turn rapidly demagnetizes and sends a surge of current back into the condenser, thus creating an oscillatory effect. This produces by induction several surges of current back and forth through the secondary winding.

Now as the turns of wire in the secondary winding of this particular coil are one hundred times greater than the turns of wire in the primary winding, the voltage in the secondary winding is one hundred times greater than the voltage set up by the discharge of the condenser in the primary winding, and is of sufficient strength to jump a long air gap or to shoot the compression in the cylinder of a gasoline engine.

It is common knowledge that the arc produced by a kick coil between the electrodes in the cylinder varies from 75 to 100 volts, according to the size of the kick coil and the amount of current used in charging it, yet the battery that is charging the kick coil may be only four or five volts. The increase in voltage is due entirely to what is called the extra current of induction, or what is commonly called "the kick of the coil." On account of having a condenser which absorbs or prevents sparking at the circuit breaker points on the vibrator, the voltage induced will be very much higher than that produced by a make-and-break spark, or "kick coil," where the demagnetization of the iron wire core is slower on account of having an arc or spark through which to let the current pass gradually.

*Extracts from a paper read before the National Gas and Gasoline Engine Trades Association, South Bend, Ind., June, 1909.

In summing up the action of a spark coil, we are brought face to face with the enormous importance of the condenser and the large part it plays in energizing the coil and producing the spark. Without the action of a condenser it would be impossible to produce a jump spark of sufficient intensity to ignite the charge.

The spark produced by a single interruption, while it looks just like one spark, if split up and analyzed, will be found to consist of several sparks; the first one will be the largest, representing the first surge of the condenser through the primary winding, and each succeeding one smaller. In other words, the oscillation dies out just as would the oscillation of a pendulum.

Spark Coil Builders' Greatest Problem—The greatest problem in spark-coil building is so to proportion the condenser and windings and so build the coil that there will be just as few oscillations of the condenser as possible, thus giving to each oscillation a greater amplitude, causing a larger spark more dynamic in its character and of greater heat value. With an improperly proportioned condenser and improperly insulated windings, the condenser discharge becomes very rapid and consists of a large number of small oscillations, which produces a static spark of no heat value and, consequently, worthless for ignition.

There is one very important feature of the action of a jump spark coil. This is the extra or additional condenser effect that is set up between the primary winding or the coil and its secondary winding, due to the common practice of connecting one end of the secondary winding to the primary winding.

When using a spark coil under these conditions, the more turns of wire on the secondary and the longer the spark gap, the more highly charged becomes this condenser.

The secondary end of the winding connected to the plug forms one plate of the condenser, and the primary winding, together with the engine, and all other parts which are connected to the primary, form the other plate of the condenser.

Now for jumping a small gap or shooting a rich mixture of low compression, when no great electro-static stress or strain is placed upon this self-constituted condenser, but when a coil of this type is used on stationary engine work, where high compressions and thin mixtures of high electrical resistances are met with, it is practically impossible to create a dynamic spark of large heat value, for the energy of the secondary current all goes into charging this unwelcome condenser, and rapid oscillations are set up which renders the spark static and of no heat value.

Improved Insulation Aggravates This—One might think that this condition could be easily overcome by having extra good insulation between the primary and the secondary winding. The fact of the matter is, the better the insulation you use between the two windings, the more aggravated these conditions become, because, as a general rule, that insulation which is the best also has the highest specific inductive capacity. A glass tube or a mica tube would be the very worst insulation to use between the primary and secondary on account of this property of high specific inductive capacity. The best that can be done is to use an insulation of sufficiently high resistance to prevent direct discharges or punctures between the primary and secondary winding, and at the same time have as low a specific inductive capacity as possible.

The only way in which this extraneous and deleterious condenser effect can be practically eliminated is by bringing out both ends of the secondary winding and not grounding either end through the frame of the engine, the primary winding, or anything else; but each end of the secondary winding should run to its own spark plug.

I would suggest for all stationary engines of high compression the use of two spark plugs per cylinder so located in the cylinder of the engine that a circle drawn from each spark plug as a center, the circumferences of these circles touching each other, and also touching the diametrical, opposite sides of the cylinder bore, thus giving each plug a position as nearly central to each half of the compression chamber as possible. This would then give a pure dynamic spark under the adverse conditions of stationary engine ignition from any spark coil of good grade and sufficient size, and would give two instantaneous sparks at widely separated points, which would tend to complete combustion of the charges very much quicker than one spark emanating from one point only.

I wish to state here, and now, that it is absolutely impossible to make a jump spark coil that will shoot compressions of from 135 to 150 pounds with thin mixtures and do it with a dynamic spark where one end of the secondary winding is grounded. I therefore strongly recommend the use of two spark plugs per cylinder and the bringing out of each end of the secondary winding of the coil to these plugs. When used in this way it is easy to construct a jump spark coil that will give a dynamic spark of intense heat and of sufficient voltage to punctuate any compression and to shoot any mixture, no matter how thin or how high its electrical resistance.

It cannot reasonably be expected that a spark coil, which is only strong enough to properly shoot 60 pounds compression, will shoot 160, but larger spark coils should be used on heavy stationary engines. True they cost more money than smaller ones, but they can be made to last as long as the engine lasts, or longer, for if properly made there is nothing about them to deteriorate.

While I have not had an opportunity to test an engine with two spark plugs and with coil as above suggested, still at the same time I would hazard a guess or prediction that this form of jump spark ignition will be found to develop greater power.

INCOMPLETE COMBUSTION IS WASTEFUL

This phase of the subject is sometimes cared for without regard for details, and the magnitude of the saving which follows if the fuel is burned to finality,

(a) Carbon dioxide (CO_2), and (b) water (H_2O).

If some of the fuel is reduced to carbonic oxide, (CO) the loss is enormous, on that account, as the following figures will adequately show:

PRODUCTS OF COMBUSTION FULL AND PARTIALLY LOADED

	Full load	Partial load	Slow free
Carbonic oxide	3.13	6.9	—
Hydrogen	1.19	2.4	—
Hydrocarbons	0.30	0.9	—
Carbon dioxide	11.90	9.9	6.3
Oxygen	.23	0.3	11.2
Nitrogen	83.33	79.6	82.5
Total	100.0	100.0	100.0

Fuel value of carbon burned to carbon monoxide = 4,400 B.T.U.
Fuel value of carbon burned to carbon dioxide = 14,500 B.T.U.
Fuel value of hydrogen gas to water = 62,032 B.T.U.
Fuel value of hydrocarbon fuels to carbon dioxide = 20,000 B.T.U.

If we assume that the total as above given is 100 pounds, and taking the fuel values as above set down for the respective elements and compounds, it will be possible to show that the loss will be enormous if the combustion is incomplete, as, for illustration, 6.9 pounds of carbonic oxide (shown at the top of the column for partial load) would mean a loss of 62,790 British thermal units of heat (B.T.U.). What is more to the point, the 2.4 pounds of hydrogen would mean a loss of 148,877 B.T.U. In the same way, all the losses may be determined.

DETAILS ATTENDING SOLID TIRE USE

In pleasure vehicles, when solid tires are used, it is well to remember that the best performance will follow if the section of the tires is not too great. The diameter of the wheel should be considerably greater than is the practice with pneumatic tires, and the weight of the rim should be restricted; this is easily attained in view of the better performance if the tire section is reduced considerably below that which seems to be good practice in pneumatic tire work. In high wheelers, tires are not made with narrow tread to save cost, as some are prone to believe; the performance of the vehicles is better, due to restricting the "bounce" which would follow were the tires in greater presence.

LETTERS INTERESTING AND INSTRUCTIVE

CAUSE OF ENGINE MISSING

Editor THE AUTOMOBILE:

[1,965]—Can you explain why my four-cylinder four-cycle motor, which runs perfectly when under moderate or heavy load, skips badly when running idle or under light load? This annoyance continues regardless of the speed of the motor or of the adjustment of the carbureter. The carbureter is a Schebler. J. R. K.

Philadelphia.

Missing is almost invariably caused by the lack of a spark, and since you say nothing about your ignition system or troubles, it is practically impossible for us to give a correct or reasonable diagnosis of the trouble. It would be well for you to look over all wiring very carefully, as it sounds like a case of a wire with the insulation worn through. With the engine running rapidly, and therefore smoothly, this bare spot in the insulation is not disturbed, but as soon as the speed is reduced the vibration begins to be very noticeable. In this latter case, the bare spot in the insulation is moved against some metal part or something which is a good conductor, and a short circuit results. The result is that no spark occurs in the cylinder, and then what happens is that the cylinder passes an explosion, or misses, as it is more usually called. That the above is reasonably close to the real trouble is shown by the statement which you make to the effect that the trouble continues regardless of carbureter adjustment.

ENGINE ABILITY

Editor THE AUTOMOBILE:

[1,966]—On my car there is no control of ignition. That is, the magneto is fixed (which is the way very many cars are being turned out this year in France). Therefore, when the car begins to labor on a hill, the throttle being wide open, even when going very fast, but slowing down, a "knock" develops. The consequence is the throttle has got to be turned off some to stop this.

My chauffeur is anxious that we should get the control of the magneto on the steering-post, which it is possible to do, but we are both in doubt as to whether the engine would develop more power with the throttle wide open and a slightly retarded spark, or a more advanced spark and the throttle half open, as it is now. I am a little doubtful if I have made myself understood, but the following is our course now in going up a long hill:

We have our throttle wide open, the engine slows down a little, a knock develops; we close the throttle an inch or more, the knock ceases. Now, instead of reducing the amount of gas in the engine, if we could retard the spark gradually as the engine slowed down, would we get more power? AMATEUR.

Toronto, Ont.

If we understand your case correctly, it would not be advisable to make the change from the present fixed spark to a variable spark position. The only difference which this would make is that you would retard the spark very slightly on hills leaving the full throttle opening. As to power, it is doubtful if the engine would develop as much on the average, although the change would allow you peace of mind as far as hill climbing is concerned, which might be worth the sacrifice of some power.

To actually obtain the maximum power, not only a full throttle opening is necessary, but also the largest possible spark advance. Pulling ability on hills, which introduces a number of other variables, should not be confounded with maximum power, the former requiring a retarded spark from the very nature of the work being done, whereas the latter calls for the greatest possible advance.

Since you have asked for our advice, which you would not do unless you wanted it, we would advise against the change, on the ground that you would lose more than you gained, since you climb hills infrequently, but otherwise run the car much.

Another and a different chauffeur probably would want the control simplified as much as possible, while this one seems to want to have it complicated more than it now is. It might be interesting to you to know that the modern tendency is away from the hand control toward automatic.

IN RE SKIDDING

Editor THE AUTOMOBILE:

[1,967]—Regarding No. 1,955 in your last issue, "What to do on wet pavement," I have found it a good thing, when your car commences to slip, particularly when not going very fast, to apply the brake without removing the clutch. If this is done gently but firmly the rear wheels will straighten out quickly and without putting much strain on the engine. When going fast and your car begins to slip, either give "her" more gas or throw out your clutch and put over your wheel so as to throw your steering wheel in the same direction as you are slipping. If you can materially increase your speed your wheels will get a better grip on the road and straighten you out OK. ALBERT J. MAYER.

New Orleans, La.

The first part of Mr. Mayer's remarks sounds all right, but as to the last part we wish to take exception to the idea of turning the steering wheel in the same direction as the car is skidding. This would simply result, when the front wheels had reached a perfect right angle to the direction of the side slip, in increasing the latter, since the resistance at the pivot point (the front wheels) is thus reduced to a minimum. In other words, it would appear to us as if this mode of procedure would increase rather than decrease the amount of the slip. The advantage of increased speed at a time like this is also very doubtful. When the wheels are already slipping and so have no grip on the road surface, it is hard to see how greater speed will increase the grip on the road. In fact, it would seem as if, granting that the trouble is due to too high speed in the first instance, greater speed later would only result in more skidding and more trouble.

Pulling out the clutch cuts off the power from the wheels, with the result that the car drives itself rather than the engine. This seems to result in the elimination of the objectionable and dangerous side slip.

CLEANING OFF CARBON

Editor THE AUTOMOBILE:

[1,968]—Will you please tell me through "Letters Interesting and Instructive" if the carbon can be burned from the tops of the pistons and from the cylinder walls by pouring coal oil into the auxiliary air valve of the carbureter, while the engine is running? ROAD EATER.

Rossville, Ind.

No. This will not remove the carbon wholly, although it may take off part of it. The kerosene in combination with the jarring action loosens some of it, but as far as burning it off that is impossible, for the carbon is a residue from a burning action. The best way is to use a decarbonizer or else take down the entire motor, scrape it clean, and then paint with a very thin coat of paraffin. It is said that this will aid very materially in preventing the formation of more carbon.

The most important thing about the formation of carbon is to learn that it is caused by incomplete combustion, which also means fuel going to waste. So you should clean the motor and then run it so as to attain the whole use of the fuel, and thereby prevent the formation of future scale to be cleaned out later on. You know the old saying, "An ounce of prevention is worth a pound of cure." It holds good in this case.

ROTARY VALVE ENGINE

Editor THE AUTOMOBILE:

[1,969]—A bit of news that will be of interest to readers of "The Automobile" at this period, when all gas-engine designers are developing gasoline motors for automobile purposes, and especially (judging from interesting editorials in your paper), the subject of rotary valves.

There are a series of tests being made at Atlanta by W. H. and E. F. White, with a rotary-valve engine upon which they have worked in an experimental manner for four years. It looks from the tests as if they have hit the mark, and will be ready to demonstrate inside of thirty days, with a motor having rotary valves in the head, cylinders in block 3 1-4 in. x 5 in., ballbearing crankshaft, water cooled by the hopper arrangement.

This engine, in its operation, does away with valve stems, springs, camshafts, water pumps, piping and radiator. It is understood that it will develop for a long test under load 40 per cent. more power than the formula used to rate gasoline engines.

I understand that the engine will be on exhibition at the show to be held here in the fall. I happened to be one of the few that found out about the construction and tests, and knew that it would be of interest to your many readers to know that Atlanta is to have the first successful rotary valve engine on the market. Another thing: it seems that these young men should be brought to the attention of the manufacturers of automobiles. They have gone about their work very quietly, and one cannot gather any information from them whatsoever, nor do they ever mention it, which I think has been a mistake on their part, as it seems that publicity is what is needed in making an article of this class. I believe that you will do them a great turn if you will mention the fact in "The Automobile." B. F. ULMER.

Atlanta, Ga.

In the statement that the engine develops more power than the rating for this sized engine, Mr. Ulmer doubtless means the A. L. A. M. rating formula. According to this, an engine of the size mentioned would be rated at 16.9 or practically 17 horsepower. To exceed this by 40 per cent. would mean that the motor must develop 23.8 horsepower, which is not beyond the range of the possible.

The statement about rotary valve engines and Atlanta having the first (in case this one is successful) is a little bit overdrawn, since several rotary valve engines have been developed in this country and abroad. For instance, in THE AUTOMOBILE for May 13, was described a new French production, the Anzani engine, which was equipped with rotary valves. This motor is successfully running to-day, as is evidenced by the fact that Bleriot's monoplane, which has just accomplished the passage of the English Channel, is equipped with a three cylinder Anzani engine.

SUGGESTS BETTER ROUTE

Editor THE AUTOMOBILE:

[1,970]—Being an old subscriber to your magazine, and a member of the Executive Committee of the Capital to Capital Highway Association, I would ask that you allow me the privilege of correcting the route given in the July 22 issue of "The Automobile," probably furnished by the press, or the Herald-Journal scout cars, as well as some of the comment thereon. These cars did not follow the true Capital to Capital route south of Columbia, S. C., and thereby encountered much worse roads and a ferry. Both would have been avoided had they followed the route below Columbia, by way of Augusta and Crawford, instead of going via Elberton, Ga. We do not wish that the Capital Highway route be misplaced so early in the proceedings, and, in justice to the roads and our own work relative to the same, do not want to be held responsible for impassable roads and a ferry which do not belong on the proper route. We are not in any way out of sympathy with the Herald-Journal project, for their progress through the country has been of vast importance in the way of stimulating good roads everywhere, and in the neighborhood of routes covered particularly. I am inclosing a correct map of the Capital Highway.

E. M. WHALEY,
Pres. A. C. of Columbia.

Columbia, S. C.

Part of the map, the part dealing with the specific change suggested by Mr. Whaley as an improvement over the one previously given, is herewith reproduced. While an inspection of the new route on a large scale map apparently shows an increase in the distance from Columbia to Atlanta of about 20 miles, this, considering that the total is about 200 miles, and taking into account the elimination of the ferry and the vastly better roads, matters very little.

MORE COMBUSTION CHAMBER

Editor THE AUTOMOBILE:

[1,971]—I have read with interest your answer to my inquiry, published in the July 15 issue, "The Automobile," but your explanation strikes wide of the mark.

After going more carefully through Prof. Watson's article, I find that his figures for an hemispherical combustion chamber are not correct; thus, taking Case C for instance: the volume is given as 233 cc., the area as 205 sq. cm., and the ratio of surface to volume as .88. This volume means a diameter of 9.619 cm. or 96.19 mm., a surface of 145 sq. cm. and a ratio of .665.

The dimensions for my own cylinder reduced to metric measurements would give a ratio of .525.

Referring to the last paragraph of your answer, I wish to say that I have long ere this been convinced that the capacity of a vessel can not very well be changed without altering the wall surface.

But in the case of the cylinder of a gas engine with a hemispherical combustion chamber, your statement is erroneous, as then the ratio of wall surface to volume is a constant, no matter what the compression may be; this is self-evident and does not even require the use of arithmetic.

To close the argument, I suggest that the blame be put on Prof. Watson, who evidently was using a cylinder with a hemispherical top of a diameter less than the cylinder, so that his combustion chamber was composed of two parts: the top, that is, the hemisphere, and the bottom, a section of his cylinder; only he did not say so.

Los Angeles, Cal. A. B. PLAUT.

Prof. Watson may have made a mistake in figuring the wall surface of the theoretical sphere, but in refiguring this, we do not agree with Mr. Plaut either. However, laying that aside, the latter part of the above letter attracts attention in that it is stated that the ratio of surface to volume is a constant. Thus, taking a full half sphere of 88 mm. or 8.8 cm. diameter, the volume is 176 cc. and the area 121.5 sq. cm. These two give a ratio of .69. If to this is added a portion of a cylinder of 80 mm. diameter (in this case the cylinder diameter), 1 inch in height adds 50.2 cc. to the volume and 25.1 sq. cm. to the area, which makes the ratio .648. A similar further addition of another inch makes the ratio .621.

STILZ ENGINE DEFENDED

Editor THE AUTOMOBILE:

[1,972]—Relative to the criticism by Hugo C. Gibson on my constant pressure engine, which was described in your issue of July 8, I would refer to an article appearing in "Engineering News" of April 22, 1909, in which there are developed the calculations involved in this type of engine. The matter there disclosed, will, I believe, refute most, if not all, of the points which he raises against development along such lines.

The statements in the criticism regarding the efficiency and weight per horsepower developed are quite true for the Brayton engine, which is one type of constant pressure engine. Nevertheless, the engine for which calculations are made in the above-mentioned article show a theoretical efficiency of 51 per cent. without the aid of an exhaust gas heater, and 74.5 per cent. with the heater. The actual efficiency from heat developed to delivered brake load will probably be in the vicinity of 50 per cent. (see equations 11, 16 and 17), and, therefore, higher than any heat motor yet produced.

The heat in the exhaust gases is most certainly not lost beyond recovery, for it may be transmitted to the working fluid when this is about to be admitted to the expansion cylinder.

The cooling of the air during compression is indeed lost work, but since the pump is a negative element, this is therefore a negative loss, and hence a gain in efficiency, since, after the work of compression is completed all the heat which was conducted from the air while work was being done upon it is again supplied while it is passing through the exhaust gas heater.

That the rotation of the engine shaft is produced by the differential action of the expansion and compression strokes is true of all combustion engines. That these operations are effected in different cylinders in the constant pressure engine is certainly not to the disadvantage of this type.

It is not difficult to imagine what opinions would be held of an engineer who would advocate replacing the cooling water of an air compressor by a heating fluid, or of one who would advise passing cold water through the steam jackets of a steam engine. And yet such suggestions would be in line with current practice in combustion engines. Of course, when operating an engine at such a very high temperature, it is necessary that the working surfaces of the cylinder and piston be provided with cooling means; but it is not necessary to include with these other surfaces of considerable area within the cylinder, which can readily be protected from such cooling action. Then, it is quite practicable to compress the charge within cylinders which are especially adapted for such purpose, instead of within the working cylinder where it becomes heated at the very time that it should be at the lowest available temperature.

The conditions which surround the working fluid of the ordinary combustion engine are a compromise between two desired opposite extremes, it being quite impossible to even approach the ideal for either operation, where both compression and expansion must take place within the same cylinder.

Then, too, where is the engineer who, from the standpoint of economy, would propose a steam engine having a clearance as large as is found in the standard combustion engine? Still, all of these adverse conditions are essential in the explosive engine, in order to make it operative; so that any further thermodynamical improvement seems impossible unless there is a change in the cycle.

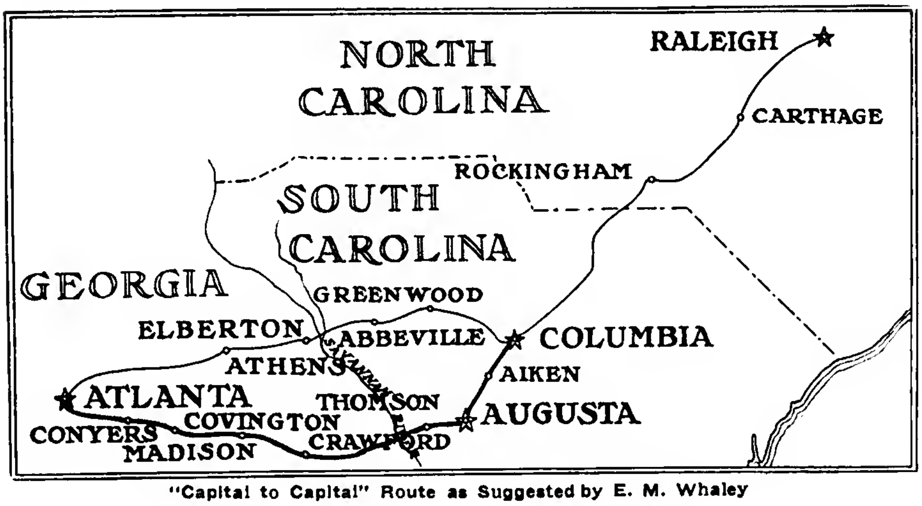
The air-cooled engine described in your issue of July 8, having two cylinders, will deliver as many working strokes per revolution as the ordinary four-cylinder four-cycle engine. It is reasonable to suppose that the two working cylinders can be constructed with about the same weight of material as two cylinders of the other type having a corresponding piston displacement and maximum working pressure. Certainly the two compression cylinders will be much lighter than the two expansion cylinders. Since the expansion and compression are effected under conditions especially adapted to their specific needs, the difference between the positive and the negative work will be a maximum, and therefore the power delivered to the shaft greater for the constant pressure than for the explosive engine. The fact that the clearance in the constant pressure engine is reduced to a minimum assists to this end. Moreover, the working pressure being limited only by the strength of structure comprising the engine, the readiest expedient is available for producing an engine of great compactness and light weight.

It is not understood why the fluid friction should be considered greater in the constant pressure engine. Certainly the passages to the working cylinder need not be of so large an area for air compressed to 500 pounds per square inch as would be required at the pressure of the atmosphere.

The serious error in Mr. Gibson's criticism lies in his desire to embody a few narrow facts about one design of engine into a set of fundamental principles which can be held to apply to any engine designed along somewhat similar lines. I am very glad, however, that these points have been raised, as such actions tend to awaken an interest in a line of effort which bids fair to be a matter of much practical importance in due course of time.

H. B. STILZ.

Bath, Me.



"Capital to Capital" Route as Suggested by E. M. Whaley

New Four-Cylinder Reo Has Graceful Body Lines, Long Wheelbase, and Large Wheels

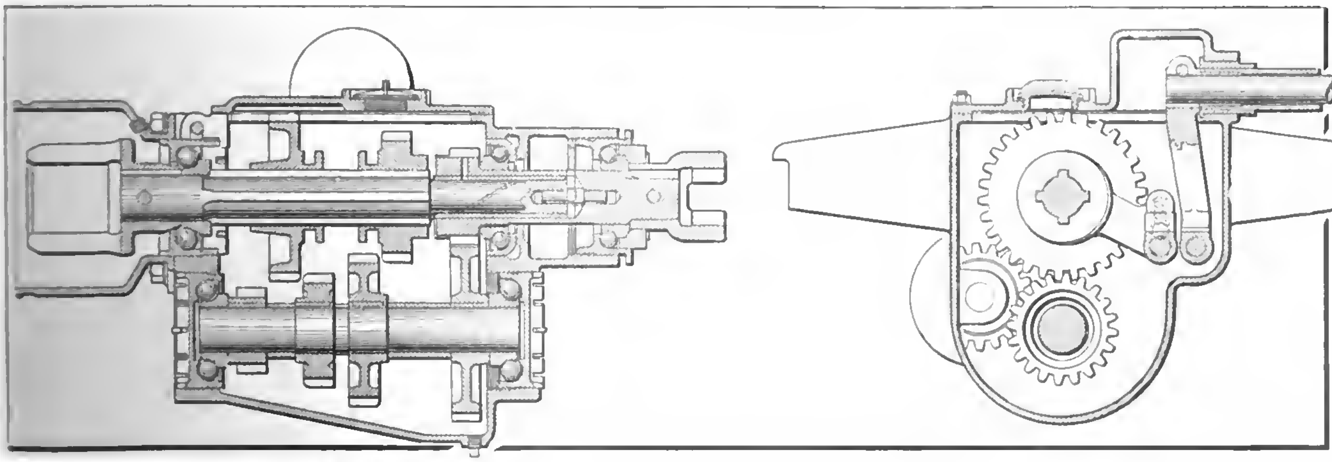
As the foremost exponent of what foreign automobile constructors have been pleased to term the American type of machine, namely, the automobile with a single cylinder or a pair of cylinders placed horizontally under the body, R. E. Olds is known the world over. The public, always fickle, however, demands new forms of construction, and to meet these demands Mr. Olds, now at the head of the company which bears as a name his initials, the Reo Motor Car Company, Lansing, Mich., has brought out an excellent example of a modern four-cylinder, five-passenger, medium-powered motor car.

This new and most popular type of machine will be known to the trade as Model R, and is rated at 30-35 horsepower. The principal body form will be the five-passenger touring car, shown in finished form in the heading above. This car, being made to meet a popular demand, will be sold at a popular price, the figure set for this being $1,250, with top $75 extra.

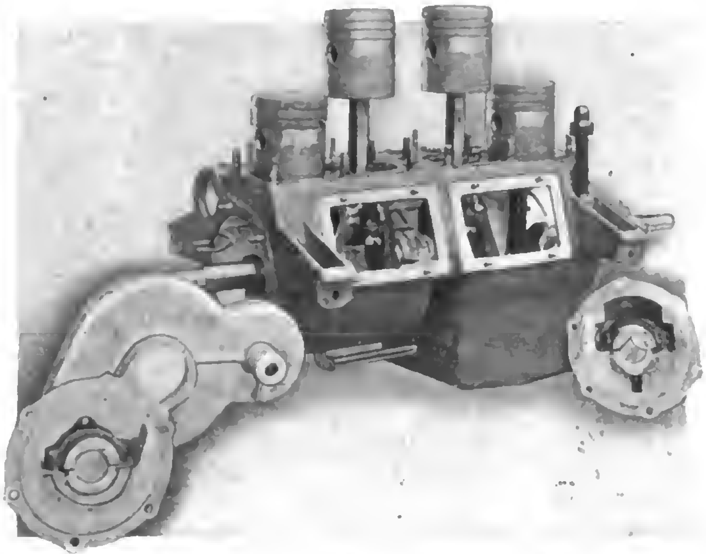
While combining the very best foreign and domestic practice, the new car will be strictly American in general design and construction, even going so far as to have the control concentrated on the left side, a practice that is gradually coming into extended use. Aside from this feature, the whole car follows standard lines as laid down by America's best designers. Thus, the body is of the modern straight line type, with approved fender shapes. The tonneau is close to the so-called baby tonneaus and yet partakes of a large and generous size, so that the occupants will not be crowded. This clever combination results in a fast, racy-looking car with very comfortable riding qualities, yet not extreme in any particular.

Large tires, coupled with adequate springing and a long wheel base make for easy riding, without which the best of other parts would be useless, and the finest design, together with first-class workmanship and material, would be wasted. The first-named, workmanship, is well cared for in the very large and modern shops at Lansing. These rank among the foremost in the country, and much time and thought is brought into play to keep them in that position at all times.

What the New Power Plant Shows—Four vertical cylinders cast in pairs characterize the motor, the dimensions of which are 4-inch bore and 4½-inch stroke. This gives a ratio of bore to stroke of 1 to 1.125, showing again the most modern tendency toward a relatively long stroke. The cylinder pair castings are of a special grade of close-grained gray iron. A one-piece crankcase is used as reducing the cost of manufacture, as being a more rigid construction, and as being more advantageous to handle, both at the factory and by the owner. This form contributes much toward the furtherance of an efficient lubricating system. The latter is of the pump circulative type, in which a large plunger pump, driven from the camshaft through an eccentric, delivers oil from the reservoir in the bottom of the case and forming part of it, to the three main bearings and to the gears. The bottom of the case is divided into a series of compartments, into which the oil drips from the bearings. These pools of lubri-



Three-Speed Selective Transmission is Small and Compact Yet Business-like



One-Piece Crankcase Unit Shows Up Well

cant then form the basis of a splash system, which takes care of the whole interior of the engine.

Lest this method prove too generous and flood the whole inside with oil, splash plates are provided which effectually prevent more than the necessary amount from rising up into the cylinders. In this arrangement of the motor oiling, there are no outside pipes to leak or otherwise give trouble, no stuffing boxes to be periodically replaced, and no adjustments to make. With a screen to clean the oil and protect the pump, and a small three-quart reservoir to be kept filled, it seems as if the important problem of lubrication is reduced to its simplest terms. Aside from the one-piece crankcase being perfectly tight, much care is exercised to have all other joints oil tight, resulting in a clean and neat power plant at all times.

High-Grade Material Freely Used—Special manganese steel is used for the crankshaft, this material being famous for its strength, rigidity and other qualities so necessary in the crankshaft. This particular steel has a tensile strength of 110,000 pounds per square inch with other qualities in proportion. The use of paired cylinder castings allows the use of a central bearing, which brings the number of crankshaft bearings up to three. These are 1½-inch in diameter, with an aggregate length of 10½ inches. This total length is one of the most important details of engine design, since insufficient length means short life and consequent expense. The crank pins are also 1½ inch in size by 2¼ inch long. Offsetting is resorted to in both the crank and camshaft, to avoid excessive side thrust, which soon wears out the parts and necessitates renewal.

Both the main bearings and the connecting-rod bearings may be inspected or taken up very readily through the two large hand-hole plates provided on each side of the crankcase. This provision for adjustment from the outside is a very important one, since otherwise it would be a source of much trouble and endless work to take down the whole lower part of the engine to perform a simple act of adjustment.

In a machine which possesses many unusual features, it is a hard matter to select a few for special mention, but a feature that at once attracts about the engine is the location and size of the valves. These are so placed as to allow of their being unusually large, the advantages of which are too well known to require additional mention here. The exhaust valve is placed on the right-hand side in a pocket, while the inlets are located in the head, in a removable cage which facilitates regrinding. The separated positions of the two allow of both being very large, which is seldom the case, despite its advantages. All valve lifters are adjustable, and faced with fibre to decrease the noise of operation to a minimum.

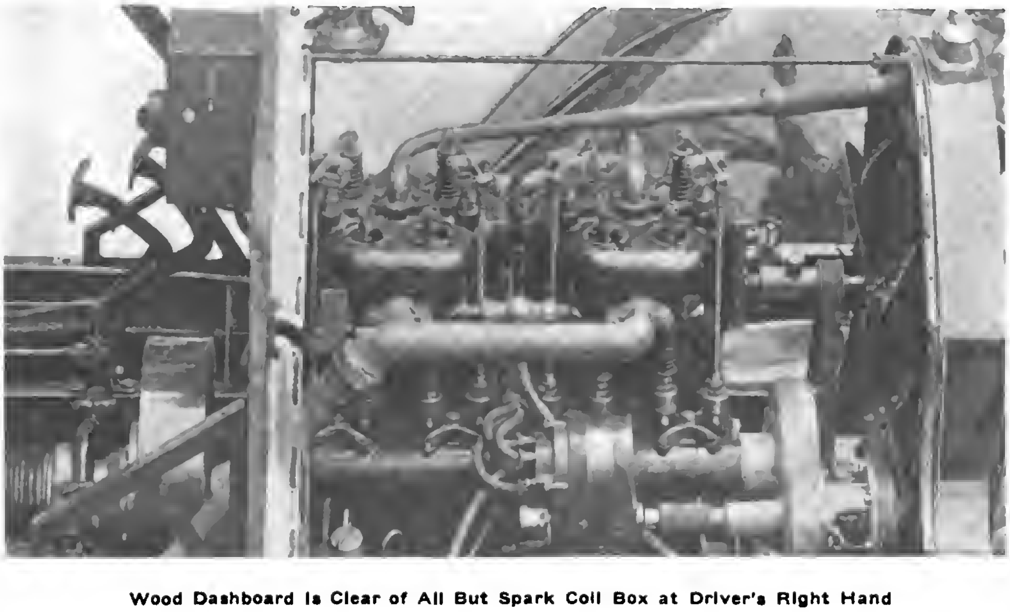
Valves of Large Diameter and Bevel Seated—All valves are bevel-seated and composed of 35-point nickel-steel heads electrically welded to cold rolled-steel stems. The silent feature is furthered by using, for the operation of the camshaft, spirally-cut gears. The shaft runs on three long bronze bearings, and is itself of a very large diameter.

Connecting rods are of a heavy I-beam section with two bolts. The latter are fitted with an ingenious locking device. A square-headed screw is used, fitting tightly in the upper part of the rod end and screwing into the lower end. Its length is so proportioned as to allow of its projecting through about an inch. Upon this extension is set a clamp, which is bound together or clamped by a small buttonhead screw. The latter is also very long and projects through the clamp so as to set against the body of the rod. By placing this clamping screw on the proper side of the holding bolt, so that in unscrewing, the bolt would bring the small set screw to bear against the rod, this unscrewing action is effectually prevented.

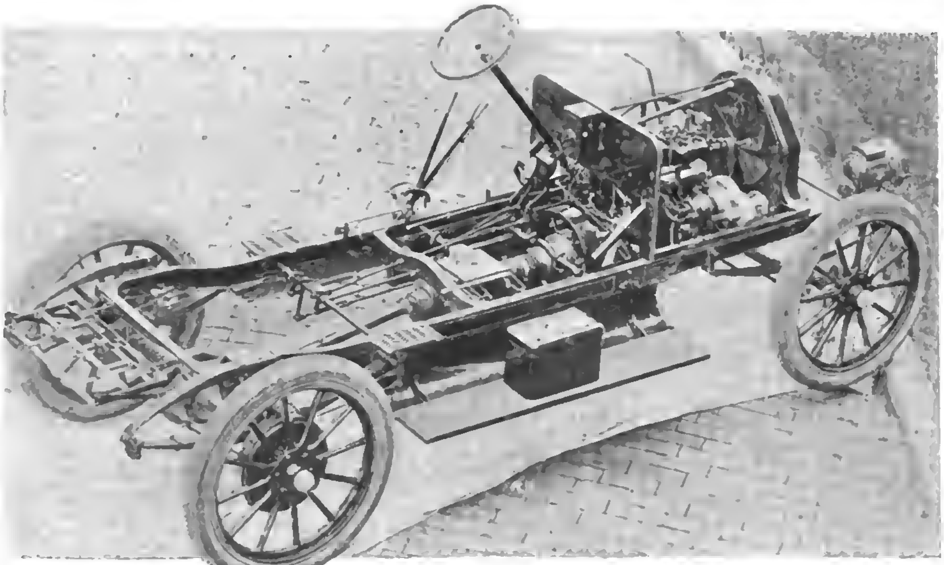
In the clutch another modern tendency is discernable. This is of the multiple disc type, with alternate discs of hardened steel and phosphor bronze.

Clutch Discs Are Hardened and Ground—The steel discs are ground after hardening to secure a perfectly flat surface. A large ball thrust takes up the spring pressure, the spring being a single, easily adjusted unit. When the clutch is out of engagement, there is no end thrust. The size and number of the plates composing the clutch are such as to secure a very large surface of contact, this allowing of simpler lubrication, smaller spring pressure, easier engagement and disengagement. The clutch connection to the transmission is through a double universal joint of liberal proportions, encased and packed in grease. It is of the full universal type and by its use complete freedom of motion, between engine and transmission is obtained.

Three speeds are afforded by the transmission, which operates on the selective plan, a swinging lever located on the inside close to the driver, where it can receive all necessary attention, being the prime mover for all



Wood Dashboard Is Clear of All But Spark Coil Box at Driver's Right Hand gears. Gears are of a special gear steel, cut to six pitch with ⅞-inch face, hardened, and ground after hardening. So, too, with the shafts, which are hardened and ground. The gears slide on four keys formed integral with the upper shaft, the lay or jack shaft being placed below the main shaft, but in the same vertical line. The case is a single casting with removable ball bearings and a single large removable top cover. The latter has an oiling aperture in the center, which allows of lubrication without removal. Shifting rods are enclosed, which with the one-piece case should eliminate the usual gear-case oil leaks.



As New Reo Looks with Body Removed to Show Construction

Both axles are conventional in so far as the general design is concerned, the front being of an I section, one-piece drop forging, and the rear, semi-floating. At the rear axle, the bevel gears are mounted on adjustable ball bearings and the outer ends of the shafts, on roller bearings. The front axle is of manganese steel, carefully heat treated, with the spring saddles forged integral. All front-axle bearings are of bronze, with hardened steel pins rotating within them. For protection's sake, the cross connection is carried at the rear of the axle.

A sixteen-inch steering wheel gives the driver command over the direction of the car through the medium of a gear of the bevel type. In this, a large diameter bevel pinion acts upon the hardened steel pinion. A single adjustment is easily accessible. The steering wheel has an aluminum spider, upon which are mounted the hard rubber rim pieces.

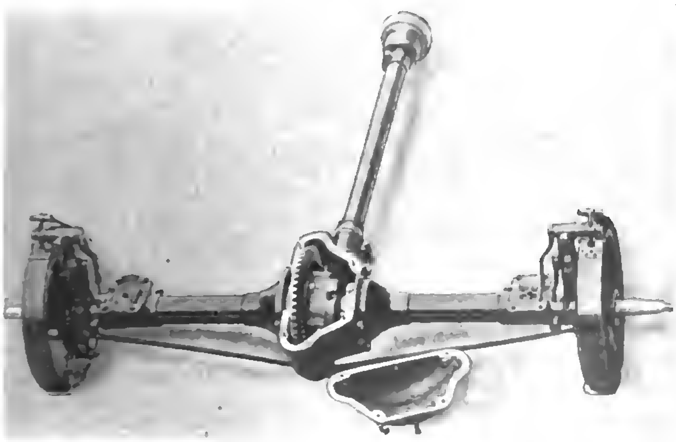
Ample clearance is provided at the low points of the chassis, that under the front axle being 12 inches. At the rear axle, the lowest part of which is the differential housing, this is increased to 12½ inches. This case is made with a large and easily removed cover, through the medium of which the driving gears may be adjusted. After removing this cover, the adjustment is simple, a pair of adjustment rings being provided, which are set into the desired position and locked. The torsion tube, which encloses the driving shaft, runs on ball bearings, these being readily adjustable from the outside.

The upper end of the torsion tube is formed by a large diameter spherical ball joint, which is hung on the rear shaft of the transmission. This, forming a universal connection at an important point, is also enclosed in grease, so as to require no outside lubrication at any time. A leather boot covers the whole joint and is protection against the loss of any grease, which would be both objectionable and dangerous.

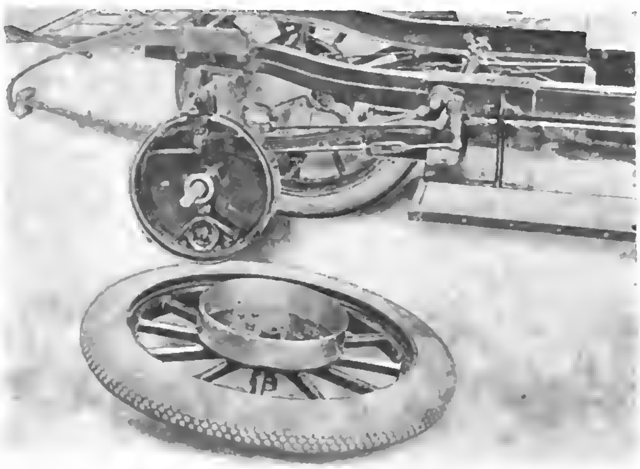
Large Wheels and Long Wheelbase Make Riding Easy— Since nothing is more desirable than easy and comfortable riding qualities, these are sought after in the use of large wheels, 34 inches in diameter, equipped with 3½-inch Michelin quick-detachable tires. So, too, the length of the car contributes much, the wheel base of 108 inches being of great service. The front axle is located on a line with the radiator, while the frame at the back overhangs the rear axle by 8 inches. This frame is of pressed steel, hot riveted and well braced. A sub-frame carries the engine and transmission, while sheet-steel sides close in the space between sub-frame and side-frame members. The frame is upswept at the rear to obtain easy riding and a low center of gravity. The sub-frame is set as a slight angle so as to help the straight line action between engine and rear axle. Springs are always an important item in the matter of easy riding qualities, and this has been covered by the use of semi-elliptic fronts and three-quarter elliptic rears, all two inches wide.

Ignition is by magneto as the principal dependance, but storage batteries are provided as an auxiliary. The magneto is attached by a single strap, so that the turning of a wing nut loosens it for removal. A universal joint in the driving shaft permits of disalignment without serious trouble.

Control is on the left side and consists of a pair of side levers, the swinging transmission lever and another for the emergency brakes. The latter is the outer lever and is interlocked with the clutch. Of the two foot pedals, the right controls the band brakes on the outside of the rear-brake drums, and the left, the clutch. A muffler cut-out pedal is also provided. Spark and throttle levers are on the steering post, but below the wheel.



Semi-Floating Rear Axle and Differential Case



Both Sets of Brakes Operate on the Same 14-Inch Drum

Viewed from the Side, Christie's Seventh Car, a Racer, Looks Very Fast and Business-Like

As an ardent and altogether consistent advocate of front driving, from the construction of his first car in 1904 right up to date, Walter Christie is well known. His long and costly apprenticeship has culminated in the present example of a chassis, designed to take either four cylinders 5½-in. bore x 7-in. stroke with a touring car body, or four cylinders 7½-in. bore x 7-in. stroke when equipped as here shown for a racing car.

Christie has built, in all, seven different cars, all front wheel drive, all wheel bases between 100 and 106 inches, wheels 30, 32, or 34 inches, all direct on high speed and all fitted with a low forward speed and reverse, two speeds only, as follows: His first car, January, 1904, had four cylinders, 5 x 6 in., with automatic intake valves. This was fitted with a 5-passenger touring car body, and weighed about 1800 pounds. The crankshaft was placed cross-wise of the chassis, in line of the front wheels, which were driven by universal shafts from the crankshaft end direct on high speed, had a clutch and 5 to 1 reduction, low speed and reverse. With its 5-passenger touring body this car had a record of a mile in 55 seconds, straightaway.

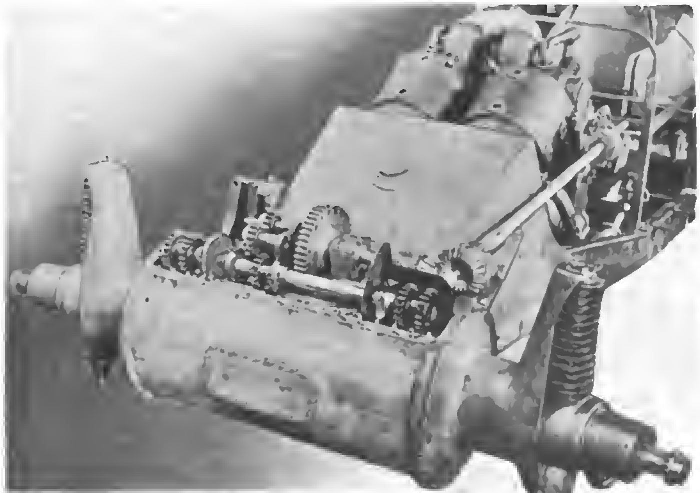
Front driving characterized the second car, January, 1905, which had the same general arrangement with four cylinders 6¼ bore x 7-in. stroke, racing body, weight 2100 pounds. At the Ormond Beach meeting, January, 1905, this car made a straightaway mile in 40 seconds, and was the only American car to finish in the International race of 100 miles, back and forth on a 16-mile stretch of beach. Christie's third was placed on the road in April, 1906; had the same front drive with four cylinders 7⅛ x 7 inches. This, like previous engines, showed a preference for short stroke.

Made a Speed of 113 Miles Per Hour—The weight was 2150 pounds. This car made a recorded mile in 35 seconds, at Atlantic City, April, 1906. This same car made 1906 mile records on circular tracks: 53 seconds at the Empire, 52 seconds at Readville, and 52 seconds at Minneapolis, which are yet the American circular track records.

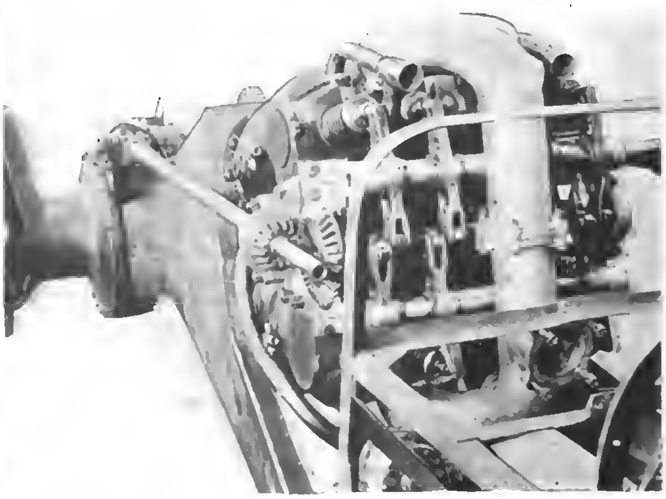
In this same year, Christie built a small touring car with four cylinders 5¼ x 7 in., automatic intake valves, 60 pounds compression and fitted with a 7-passenger touring body. Weight 2300 pounds with touring body and 1900 pounds with racing seats.

This Christie racer was entered for the 1906 Vanderbilt race, but broke a steering arm at East Williston, L. I., before the race, ran into a telegraph pole, was wrecked, and was never rebuilt. Christie ran the race with his little 1906 car and nearly finished the ninth lap of the Vanderbilt course at the time the winner finished his 10th lap. This small 1906 car was subsequently purchased by W. Gould Brokaw and taken to France, where it made 290 miles on 10 gallons of gasoline, 29 miles to the gallon, two passengers up.

His fifth car was a new chassis built to take the 1906 motor placed on the road in July, 1907, and entered for the French Grand Prix race of that year. The car was forced to withdraw



Transmission Is Simple and Placed Over Front Axle



Overhead Valves Are Used and Very Large Carbureter Pipe with a broken valve stem at the end of 235 miles. This car did a mile at Ormond Beach, March, 1908, in 33 seconds, not officially timed.

Sixth on the list was the front drive cab, placed on the road June 1, 1908. The motor is four cylinders, 3¼ x 5 in., 60 pounds compression, all valves mechanically operated.

Seventh and Last Car a High Power Racer—Lucky seven is the number held by the car here shown, which was placed on the road July 8, 1909. This car is fitted with three sets of wheels, 30-inch for circular tracks, 32-inch for road work, and 34-inch for straightaway road or track racing.

Long Front Slope Which Eliminates Wind Resistance

This is a long record of experimental cars, all of which were fast, economical of fuel, and showed the advantages of front drive.

Undoubtedly Christie erred in his choice of automatic intake valves, abandoned in favor of mechanical operation in the last two models, the cab and 1909 racer.

Herewith is shown the car which was built to show the advantages of the front drive under all conditions, and is fitted to take not only the three sets of wheels, but two different motors. One, here shown, for racing, four cylinders, 7½ x 7 in., and one for touring, four cylinders, either 5½ x 7 cr 6 x 7 in., so, with this one chassis all conditions can be met to give needful comparisons with rear driven cars.

In car number five, the cylinders were inclined somewhat to the rear, to obtain a better distribution of weight, and in this seventh model, the cylinders are very much inclined. The connecting rods are made extremely long, 30½ inches, to carry the cylinders far enough to the rear to equalize the front and rear tire loads. This car in racing form is expected to make the straightaway mile in 30 seconds, and the novelty of form and arrangement lend great interest to its future.

Details of the Present Car, Inclined Cylinders Noticeable—The front wheel drive, direct from crankshaft to front wheels, gives the latter a heavy load to start with, if the cylinders are vertical. This load would be increased by placing the radiator in its usual position. This 1909 racer is designed to place about the same load on each axle. For a touring car with this same general chassis arrangement the radiator will be much lower and the front-board, placed close to the cylinder heads, will stand in about the usual location on the chassis.

Greatly varied from the ordinary form is the front construction by carrying the frame up to take the motor-base. This is finished to two angles to take the two banks of cylinders. The motor-base is flanged all around, 3 inches in depth, and the side flanges are riveted to the frame extension. An inclined cover extends forward and is riveted to a full length bracket, integral with the cylindrical bronze crank box. This is opened on top to take the low speed and reversing gears, while a flat part of the crank box top is planed to take the slow speed shaft bearings. The camshaft is driven from the first shaft through two pairs of bevels.

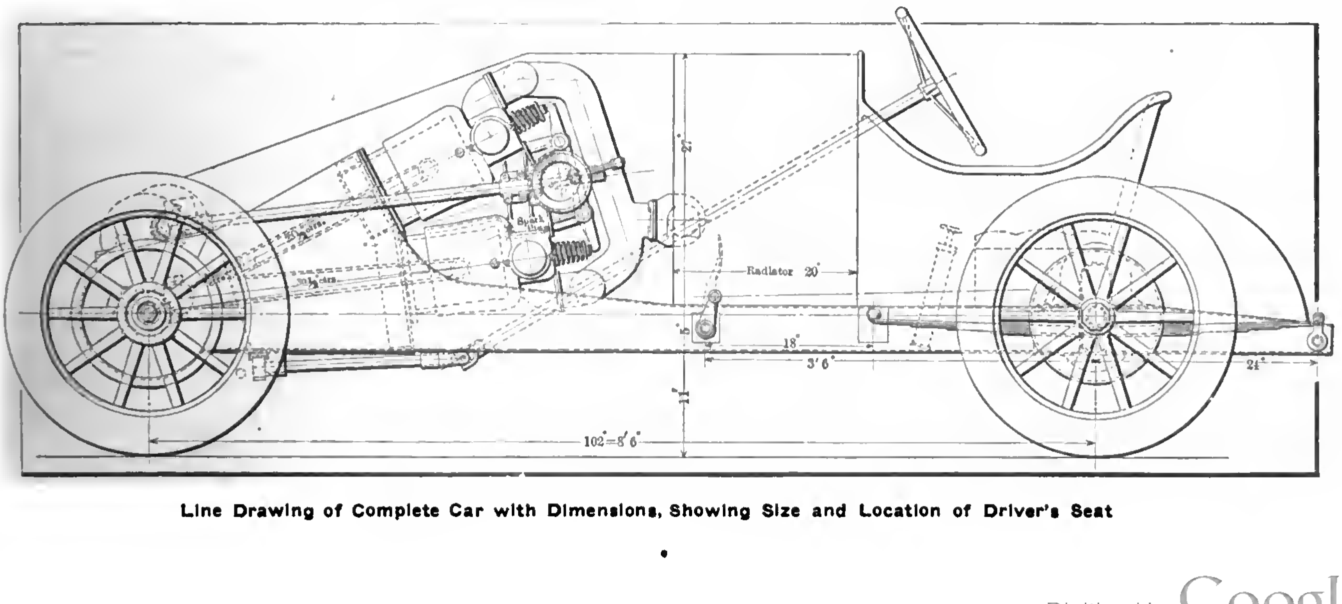
Unusual Size and Shape of Radiator—The radiator is very large, open-arched in form, 29¾ inches high by 35 inches crosswise and 32½ inches lengthwise. It is made up of 80 tubes in two arches, 40 tubes in each arch, total thickness 2 5-8 inches.

Like the radiator, the motor is an unusual form; the crankshaft has two throws only, and the cylinders are single units placed in upper and lower pairs, the center line of the latter at an angle of 8 deg. and that of the former 28 deg., to the horizon, making the angle between the pairs 20 deg. The two lower connecting rods go directly to the cranks and are 30 1-2 inches center to center. The upper connecting rods are 23 1-2 inches, center to center, and do not go to the crank pins, but are jointed to the lower rods at 7 inches radius from crank pin center.

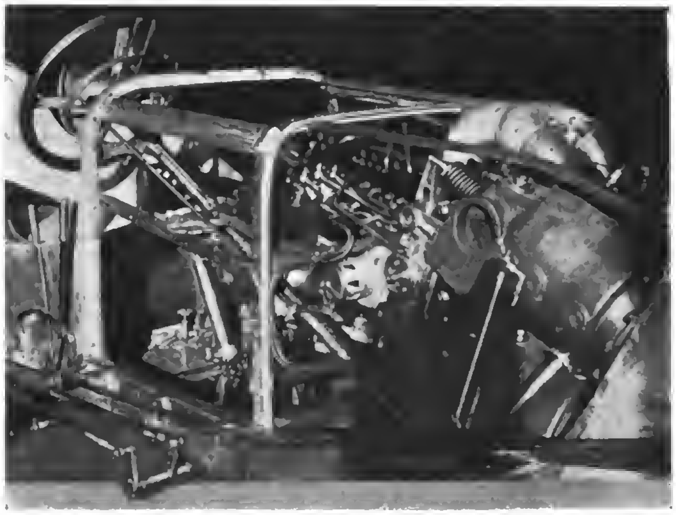
This angular separation of the two pairs of cylinders permits placing the camshaft in the rear of, above, and between the cylinders, with integral cams.

The front wheels have steel hubs and inserted tubular spokes. The rear wheels have integral steel casting brake-drums and spokes, to which the tire-rim is applied.

How the Transmission Works—The crankshaft is normally free, and at each end carries the driving members of a disc clutch which can be clutched to the inner ends of the universal shaft sleeves. To obtain low speed and reverse, the intermediate crank-arm is given the form of a toothed gear, 11 inches pitch diameter, which engages a pinion 8 inches pitch diameter, fitted with a multiple disc clutch. The integral pinion shaft has fixed to its left end the first bevel pinion of the camshaft gear train, which is thus driven when the crankshaft runs. The right-hand pinion drives a third pinion through an intermediate second pinion



Line Drawing of Complete Car with Dimensions, Showing Size and Location of Driver's Seat



Accessories Are Conveniently Located Inside Radiator Arch

to obtain reverse; it also engages a transfer pinion, and between the reverse pinion and the transfer pinion, there is placed a gear fixed to a sliding shaft.

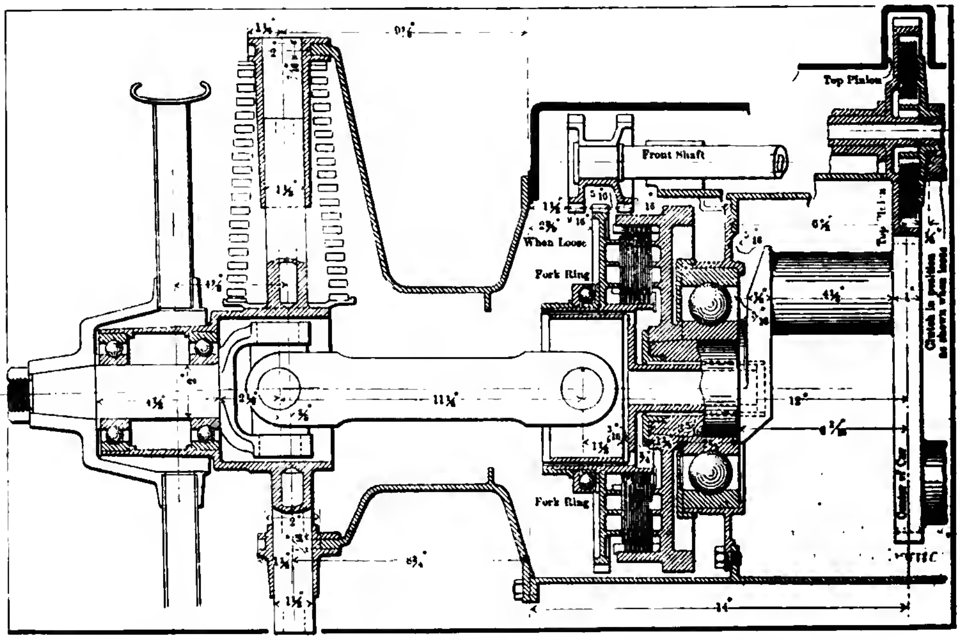
Operation of this drive is as follows: With all clutches disengaged, crankshaft driving the camshaft gears and camshaft only, the motor is started by giving a double stroke to the hand operated gang of four charging pumps. Then, with the motor working, the top pinion clutch is engaged, starting the reverse and forward slow-speed pinions; according to direction desired, the front shaft is made to slide to the right for backing or to the left for slow forward. Front shaft pinions slide into engagement with universal-sleeve gears, and so start the front wheels. The front shaft is made to slide endwise by rocking a vertical fork-shaft interlinked with the direct drive clutch fork, so that when the direct fork is moved the front shaft slides the low speed pinion out of engagement before the direct drive clutch is operatively engaged. Reverse is not interlinked with direct clutch.

Differential Is Eliminated—This form of front drive does not include a "differential." Two pairs of pinions, one pair on each end of the front shaft, have considerable "lost motion," so that the outer wheel can overrun the front shaft in turning corners. The regular touring car drive will include a bevel balance gear on the front shaft. For turning very short corners with the direct drive, the clutch pressure is partially removed by foot pressure. For rounding large radius curves, the drive takes care of itself. This method of gaining the advantages of the differential without its inherent complications is more than praiseworthy.

Christie's "self-starter" is a bank of four carbureter-sucking pumps. 1 3-8 bore by 8 inches stroke, all four piston rods being fixed in one cross-bar used as a hand-grip by the driver who first pulls towards him. filling the pump barrels with mixture from the carbureter; then pushes inward, discharging the mixture through 1-8-inch pipes into the cylinder. The starting spark is had from a dry battery through a hand-moved commutator which delivers a spark to each cylinder. The regular ignition is by two magnetos, the angularity of the cylinders making it impossible to time correctly the spark with a single magneto. The magnetos and the commutator are driven from a rearward extension of the inclined bevel gearshaft, the magnetos, by spur gears, and the commutator, by a bevel gear. The hand-starting pumps, magnetos and commutator are all placed on supports inside the radiator framing, and are covered by the radiator when in position. This makes all accessories handy to the driver.

Wheels Are Special With Steel Tube Spokes—The front wheels for this car are 30, 32 and 34 inches tire diameter; three entire sets of wheels. Spokes are steel tubes, 1 5-16 diameter outside, walls 3-32 thick, inside ends forced into seats in the steel hub. The outside over-all diameter of the spoke sockets is 8 1-2 inches and the inside diameter of the spoke socket circle is 6 inches. The spokes abut against shoulders in the sockets. The hub is deeply cupped to go over the ball-bearings, the cup being 4 5-8 inches total depth, 3 inches from the center of the sockets to the inside of the hub-flange, which is 9-16 thick in the vertical member and 3-8 thick in the cup-wall. The outer end of the hub is keyed on the stub-axle taper and held up with a hex nut. The hub taper seat which takes the stub-axle is 2 1-2 inches long, outside diameter, 1 7-16, inside diameter, 2 inches. The universal joints have yoke eyes 13-16 thick, 5 inches over all, 3 3-8 opening to take the cross-body, 2 1-8 diameter, which is shouldered down to 1 1-2 inches diameter for the cross trunnions. The universal shafts are 2 1-4 inches diameter, steel, solid, and have forks 2 3-4 inches wide x 13-16 greatest thickness. The universal forks are turned to globular form outside. The joint trunnions are hardened steel bushes, forced in, and have 7-8 holes through them, these holes being threaded at the outer ends to take threaded heads, 1-4 thick. This construction leaves a large chamber in the cross-hub which is packed with heavy grease. Shallow cuts are made in the trunnions to deliver grease to the inside ends of the bearings in the yoke eyes, this grease working outward by centrifugal action. The universally jointed stub-axles are in two circles of 11-16 diameter balls, ball circles about 3 3-16 diameter and 3 3-8 between circles.

Details and Dimensions of Axle Sleeves—These are 5 7-8 outside diameter at inside ends, 4 3-8 long, bored 5 3-8 to take the universal joints inside; this inside part has integral trunnions, vertical when placed in the front axle shell, trunnions each 1 1-2 inside diameter, upper trunnion 10 1-16 and lower trunnion 9 1-16 inches, trunnion end to sleeve center. These trunnions, on which the front wheels swing in steering, are bored 5-8 diameter for the top one and 3-4 diameter for the bottom one from the outer ends to the hub sleeve. These slide in a bronze bushing below and a nickel steel bushing above, these bushes being provided with double flanges which take the axle yoke flanges in the grooves, where they are secured with five screws 7-16



Construction Drawing of Front Drive and Section Through Transmission diameter. The outer member of the axle sleeve is 4 3-4 outside diameter and 4 3-8 inside diameter, flanged to stop the ball cups, as before described.

This axle sleeve has about 5 1-2 inches clear vertical travel by the sliding of its integral trunnions up and down.

Front springs are volute (spiral), rectangular in section, 11-16 x 1-4, 4 1-2 inside, outside diameter at bottom and 3 1-4 outside diameter at top end, 18 turns, 17 spaces 1-4 inch wide, giving 4 1-4 inches spring closure. This spring closes under 800 pounds load and carries about 600 pounds when standing still on the road. The lower end of the spring rests on a flanged steel washer, 4 3-4 inches outside diameter.

Because of greater length, owing to the spring placing, the top trunnion is made the heavier, and is supported in a nickel steel sleeve, while the shorter and lighter lower trunnion is supported in a bronze sleeve.

The steering arms are nickel steel forgings, oval section at the root, about 1 1-2 x 1 1-8, applied to the large part of the axle sleeves and retained with 11 rivets, each 5-16 diameter. The steering arm eyes, 1 1-4 diameter by 9-16 thick, with 5-8 diameter pin-holes, are about 12 1-2 inches radius.

Another Strong Supporter of the Disc Clutch—In the Christie front drive there are three separate disc clutches, one in the top pinion, and one at each end of the crankshaft. The discs are all spring tempered, saw steel, ground flat. The top pinion clutch has 10 discs, 6 1-8 inches effective outside diameter. The direct drive clutches are each 18 discs, 11 3-8 effective outside diameter x 7 3-16 inches effective inside diameter. The top pinion clutch is normally disengaged, has no spring, and is engaged by pushing the engagement-disc capped-and-pointed-sleeve-end into engagement with the short arm of the engaging bell-crank, the points of contact being hardened. The crankshaft clutches are normally engaged by spring pressure applied to the clutch linkage; the engaging fork ends, hardened, bear against a hardened ball thrust bearing ring. The fork hand lever is in a quadrant and is latched to hold the clutch out.

All principal members are carried on ball-bearings, Hess-Bright, including the crankshaft, camshaft, and bevel gear shaft. The front and rear wheels are on ball-bearings; the crankshaft bearings are very large, 8 7-8 inches outside diameter, balls 1 5-8 inches diameter.

Front axle is a cylindrical bronze casting, 15 1-8 inches diameter, 3-16 wall thickness, flanged at each end to take bronze heads, which are cast integral with the spring forks. The diameter of the spring forks member is 7 1-2 inches, walls 3-16 thick.

The rear axle is a steel tube, 2 1-4 diameter, with 1-4-inch walls, the axles 1 3-4 diameter, entering the tubular body, retained by shrinking and pinning.

Naturally, the Springs Are Decidedly Different—The rear springs are semi-elliptic, 48 x 2 inches, 5 leaves, top 3 leaves banded together, front eye jointed to frame, rear eye linked to frame by links in tension, spring passing under axle. The rear axle travels up and down in slots in the manganese bronze castings which form intermediate members of the frame sides. The frame sides are of sheet steel 1-8 thick, 5 inches greatest depth in rear of motor x 1 1-2 inches wide. The greatest side-frame depth occurs at the top corner of the motor base, and is 21 3-4 inches. There are two widths to the frame, 30 inches rear to front of radiator, then drawn in on a straight taper to 18 1-2 inches width where the frame front end joins the cylindrical box which forms the body of the front axle.

Save for unusual connecting rod length, the motor is of ordinary water cooled construction, cylinder bore 7 1-2 inches, all valve ports 3 inches in diameter, all valves mechanically operated and all located in the cylinder heads. The piston packing is four snap rings, all above the piston pin. The camshaft is midway between the cylinder heads, and the valve action is by beams turning on hollow shafts.

Water circulation is by a two-pinion water pump, chain driven from the rearward prolongation of the side shaft.

The crankshaft is a steel forging, 19 inches over all, having two crank-throws, 3 1-2 inches radius, cranks set at 180 degrees. The crankshaft has journals 3 1-2 inches diameter at each end, in Hess-Bright ball-bearings about 8 13-16 diameter, 1 3-8 diameter balls. The crank-arms are each 7-8 thick. What would be the middle crank-arm is a gear, 1 inch face, 11 inches pitch diameter, which engages the 8-inch pitch diameter pinion to drive the top shaft. The crank-wrists are 3 inches diameter x 4 1-2 inches long. The connecting rod wrist bearings are offset on the rod. The ends of the crankshaft are tapered and fitted with nuts to force the friction disc clutch cup onto the taper, which is about 5 degrees.

The brakes are internal, only, in the rear wheel hub-drums, are 14 inches diameter x 3 1-2 inches face, and are fiber-faced expanding bands, one end of the band fixed and the other end jointed to the short arm of the brake rock shaft.

Carbureter an Original Design with One Standpipe—The carbureter is Christie's own construction, a float feed with a single standpipe, an automatic air intake and a mechanically operated air admission which is linked to the throttle, so as to decrease air supply as the volume of cylinder charge is diminished. The carbureter supply pipe is of very large diameter.

Steering action is by a pinion and rack, hand wheel 18 inches in diameter, steering shaft pinion 2 1-2 inches pitch diameter, one turn of the hand-wheel to full sweep of the front wheels. The spark control is forward of the hand wheel and stands upright for ordinary position. The throttle control is at right side and forward of the hand wheel. There are three pedals on the footboard, one for the brake and two friction clutch pedals. There is a small lever latched in its quadrant, at the driver's right, which disengages the normally spring engaged, high-speed clutches, these being of the multiple disc type.

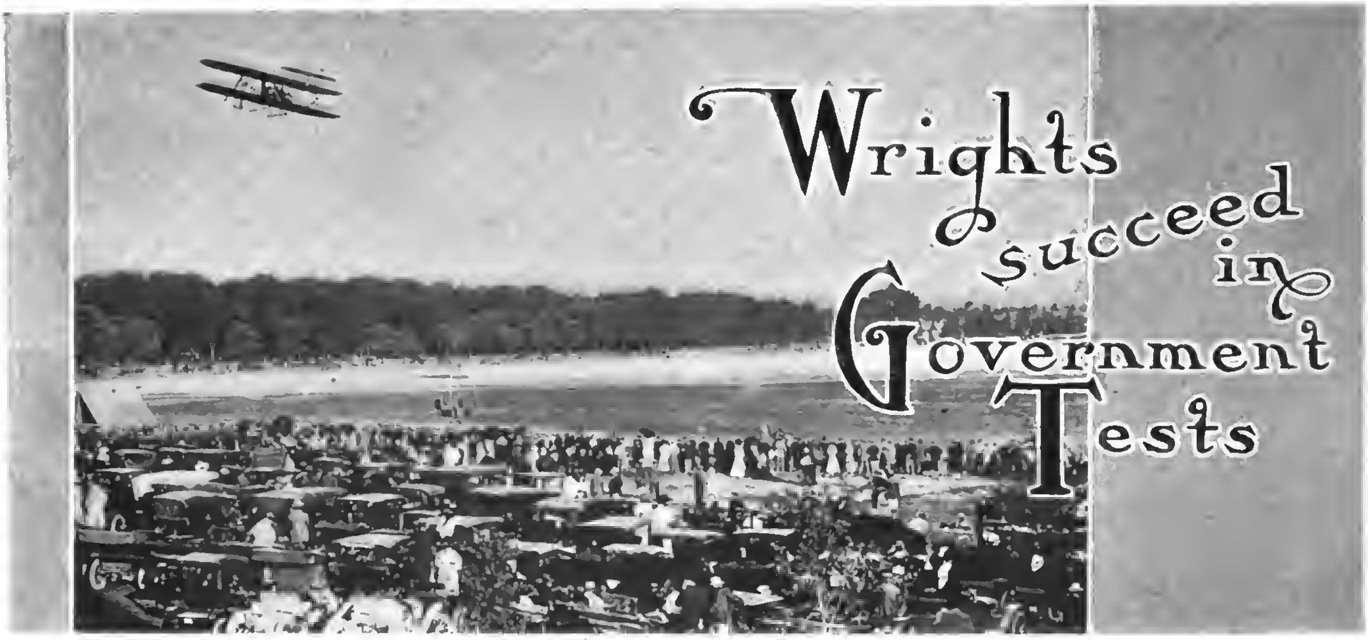
CHRISTIE THE BRIGHT STAR AT GROSSE POINTE

DETROIT, MICH., Aug. 2—When, during the first day of the "national circuit" automobile races at Grosse Pointe track last Friday, Walter Christie in his 100-horsepower space-eater negotiated a mile in 57 seconds, a new mark was set for the local track. Saturday Christie not only repeated, but clipped nearly three seconds off his former achievement, making the mile in 54 3-5 seconds. Christie's course was surrounded by difficulties. The track was not banked sufficiently at the turns to permit his making them at anything like full speed. As a result he was compelled to shut off his power and make the curves under the tremendous momentum gained on the straightaway. Once the turns had been covered, the gray racer fairly flew through the air, the half-mile mark in one trial being passed at a speed of over 100 miles an hour. Christie is confident that on a straightaway like that at Ormond Beach he can do a mile in 28 seconds with this car, and those who witnessed its performance believe he can.

Christie had as rivals Barney Oldfield, S. K. Crocker, Joe Matson in the Chalmers-Detroit "Blue Bird" (with which he won the Indiana Trophy over the Crown Point course), Billy Knipper, Gelnaw and others, but his record was never in danger, although good time was made in the various events.

Matson, in a Chalmers-Detroit, did five miles in 5:48 4-5, an excellent showing for a 30-horsepower car, and twenty-five miles in 29:36 2-5. In the fifty-mile event, Knipper in a Chalmers-Detroit put one over on Matson, his teammate, making the distance in 58:13.

"Mistah Jack" Johnson, colored pugilist, who modestly announces his desire to become a professional auto racer, drove out to the track, and divided attention honors with the speed stars.



Start of the Official Trial for Speed at Fort Myer, in Which Orville Wright Made a World's Record of 42.6 Miles Per Hour

WASHINGTON, D. C., July 30—This evening Orville Wright successfully made the second of the two official test flights, a ten-mile cross-country trip, and his aeroplane has been accepted by the Government. The average speed was 42.6 miles an hour, and as the contract price was $25,000, with a bonus of $2,500 for each mile over 40 miles an hour, the Wright brothers receive the snug total of $30,000. Incidentally, the flight may well be called a world's record, as never before has an aeroplane flown over such rough country, and that, too, with a passenger on board.

The course was a five-mile air-line to Shuter's Hill, near Alexandria, Va., and return to Ft. Myer. The turn and the half-way point were marked by captive balloons. The original time limit to the flights expired last Wednesday at midnight, and the Wrights attempted to complete them on time. Wednesday, however, was a day of disappointments. A high wind in the morning wrenched loose the balloons marking the course, and one of them was lost. At 7 o'clock the machine was brought out, but the motor refused to work and much time was lost before it was finally discovered that the gasoline feed pipe was clogged up. By the time it was in running order again it was too dark to fly, and the crowd went home disappointed.

Wilbur Wright then conferred with Secretary of War Dickinson and obtained a three-day extension of time. Thursday a severe rainstorm prevented any flights. The brothers wanted to make a trial in the early morning the next day, but as the army officers, who were to act as observers at Shuter's Hill, would have difficulty in reaching their posts on time, it was agreed not to attempt this unless to-day, too, was unpropitious.

The day opened with a series of thunder showers, and it was not until the middle of the afternoon that it seemed possible to hold the trials. About four o'clock the clouds began to break up, and at six the aeroplane was brought out and set on its starting rail. Some time later Wilbur and Orville appeared, accompanied by Mrs. Wright and Miss Katherine and a party of friends. After a conference with the judges, Wilbur dragged a big rock out into the middle of the field and laid it on top of a square white cloth. The white mark on the dry grass of the parade ground was to show Orville when he crossed the starting line, from which he was to be timed.

Then Orville and Lieut. Foulois, who was to be the passenger, started the motor. It skipped several times and needed some adjustment to the spark-timing before it would operate satisfactorily. At last all was ready. Lieut. Foulois climbed into the middle seat, next to the motor, and Orville, dragging his cap down over his eyes, took the driver's seat. The motor speeded up, and the propellers threw a hurricane of wind behind them.

"All ready!" shouted Wilbur; Orville nodded, and released the starting clutch. The aeroplane slipped easily down its rail and swept across the field, very close to the ground. To many of the spectators it seemed that the start was a failure. But on the turn near the balloon shed Orville tilted his forward plane and the machine rose gracefully. A cheer broke from the spectators. Two circuits of the field the machine made, rising higher and higher, until at an altitude of 150 feet he crossed the line and shot away to the south. The time was 6:48:30.

The first balloon at the two-and-a-half-mile mark was easily visible, and the fortunate spectators with field glasses could make out the second at Shuter's Hill. The aeroplane was seen to head slightly to the west to meet a cross wind from that direction, but soon after was lost to sight. The two narrow edges of the planes are all it presents to the view, and they are very hard to distinguish in the twilight at any distance. The spectators at Ft. Myer had to wait some ten minutes before the keenest-eyed among them could distinguish those two thin lines against the gray sky.

Then came the most dramatic moment of the flight. As the aeroplane was crossing the deep valley that lies across the course nearest to Ft. Myer, it suddenly plunged downward and disappeared behind the hill. A downward draft of air had caught it and pulled it down from its path. The crowd remembered the accident last year, and held its breath. But soon the machine came in sight again, struggling up the hill of air with the propellers whirling at full speed. After the first gasp of relief there was frantic cheering. That was the last incident of the flight. The aeroplane swept on toward the parade ground at express train speed, crossing the line again at 7:03:10, made a sweeping circle about the field and settled to earth as lightly as a drifting leaf. The cavalrymen had all they could do to keep back the crowd that would have rushed out to congratulate the successful aviators.

Later in the evening reports came in from Shuter's Hill. The army field telephone had refused to work, and there had been no means of communication with Ft. Myer. The aeroplane had appeared over the tree-tops almost unexpectedly. The officers of the Aeronautical Board were still struggling with the refractory 'phone when a trooper dashed up on the gallop and announced that it was in sight. The machine swung a wide circle around the balloon that marked the turning point, nearly 300 feet in the air, and then tilted the planes and rose even higher as it straightened out for the return trip. It had disappeared over the hills in less than a minute after it first came in sight. Orville seemed as much at ease as if he were driving an automobile, and Lieut. Foulois held his field glasses steadily to his eyes.

The elapsed time of the flight was about 14 minutes and 40 seconds, but the official time will be less than this, as the turn around the balloon at Shuter's Hill is regarded as a control. For some reason the board declined to give out their time, but announced the average speed as 42.58 miles an hour.

The Wrights Planning for the Future.

WASHINGTON, D. C., July 31—The Wright brothers and Miss Katherine Wright left to-night for Dayton, O., bearing among them a Government order for $30,000 in payment for the aeroplane. Before their departure the brothers submitted to an interview, during which Orville said that had it not been for the troublesome cross wind and the down-draft in the valley on the return trip the aeroplane might have averaged a speed of better than forty-five miles.

Wilbur Wright had a long conference with General Allen, of the Signal Corps, and although neither would make any statement, it is believed that the army chief wished to know whether the Wrights would not furnish aeroplanes on future orders at about one-quarter of the present price. Orville was authority this morning for the statement that the price of aeroplanes for private individuals will be about $7,500. The heavy price paid by the Government may be regarded as a penalty for the extremely severe tests required. An aeroplane is already being manufactured at Dayton for Russell A. Alger, of Detroit, and many other amateur aviators have filed orders. The brothers. however, have adopted one rigid rule—that they will never sell an aeroplane to any man unless he shows a marked aptitude at controlling it.

As soon as the brothers return from Dayton they will begin the training of the Signal Corps officers in the management of the aeroplane. For this purpose a tract of land has been selected in Maryland, just below Washington, which is much better fitted for use as a training ground than Ft. Myer. The brothers also have a contract to demonstrate their machine for the German government. It is probable that Orville will undertake this alone. while Wilbur remains at Washington.

GERMAN AERO SHOW IN PROGRESS

FRANKFORT, GERMANY, July 29—The first international aeronautical show ever held is now open at Frankfort-am-Main and will continue till the middle of October, forming the center for tests and ascents of numerous new dirigible balloons and aeroplanes. The new central exhibition hall is flanked by a variety of sheds for the accommodation of airships already arrived or on the way. Conspicuous among these is the mushroom-shaped hangar of the Gans-Fabrice aeroplane. A spacious test ground has been laid out, but up to the present time the weather has rendered it impossible to hold any of the competitions for balloons, aeroplanes or dirigibles in which the program is so rich. No less than 450 exhibitors have taken a share in the proceedings.

In the central hall attention is at once drawn to the fully inflated balloon "Preussen," which fills up the space under the doomed roof and which holds the present height record of 10,500 meters, accomplished in 1901 during a meteorological survey. Then the Krupp and Ehrhard stands with their balloon guns are of no little interest. Krupp, however, believes that guns are of no avail for fighting airships and that it is a case of setting a thief to catch a thief, a prognostication that brings aerial warfare within the bounds of possibility.

The aeroplane section is rendered interesting by the presence of a Wright flyer; a second one will be used in the outdoor department for demonstration work. There are also to be seen the Voisin and Gans-Fabrice aeroplanes, the Grade flyer, the Lilienthal monoplane lent by the Munich museum. propellers, models innumerable, aerial motors, scientific instruments, diagrams, parts and accessories. The Continental Rubber Company, which made the envelopes for Zeppelins II, III and IV, the second Parseval, etc., is showing its balloon materials, as are also Metzelers, Clouths and Peters.

Outside around the aviation park the sheds are grouped, the Zeppelin home being by far the largest of all. Zeppelin III is expected to arrive late in August when Count Zeppelin will gives a series of tests, without carrying passengers.

"SILVER DART" AEROPLANE IS WRECKED

OTTAWA, ONT., Aug. 2—The aeroplane, "Silver Dart," with which W. W. Baldwin and J. A. D. McCurdy made many successful flights at Baddeck, Nova Scotia, last winter, was wrecked this morning at Petewawa Military Camp, where trial flights were in progress for the Canadian government.

The aeroplane had made four successful flights of half a mile each at a speed of more than forty miles an hour, with both aviators on board. On landing from the fourth trip the sun rising over the hills shone squarely in their eyes, and as they were descending the machine struck a knoll, ricochetting and striking again with such force as to wreck the wings and controlling apparatus. The two operators escaped with a few scratches and bruises, and were enthusiastic over the performance of the machine before the accident. They already have a new aeroplane under construction.

The "Silver Dart" was the product of Prof. Alexander Graham Bell's experimenting association, which built several machines at Hammondsport, N. Y., before moving to Nova Scotia. Glenn H. Curtiss, at present engaged with his aeroplane at Mineola, L. I., was formerly with the association.

HERRING AND GOVERNMENT DEADLOCKED

WASHINGTON, D. C., Aug. 2—Apparently the War Department will be content with the Wright aeroplane this year. Gen. James Allen, Chief Signal Officer, said to-day that he had heard nothing further from A. M. Herring since he notified him last Saturday that his contract could not be extended again. Mr. Herring's time for delivering the aeroplane expired last Saturday. General Allen says that he was sure no more aeroplane contracts would be let this year.

Reports from Mineola, L. I., say that Mr. Herring has his aeroplane nearly ready for trial. He says that he will demonstrate what his machine can do and that if the Government wants it he will be prepared to deliver it by September 1. If the Government does not want it, Mr. Herring asserts that he will be able to dispose of it to a foreign government.

Where the Nation's Chief Executive Witnessed the Flight

Seated in the President's tent, from left to right, were Senator Aldrich, of Rhode Island, President Taft, Representative Payne, of New York, and General Edwards.

SIMPLEX WINS BRIGHTON'S "24"

The Simplex Camp

"Wag" as the "Man with the hoe"

When the Struggle was at its height

Robertson and Poole.

Among those who Officiated.

Simplex winner, and Rainier runner-up

Waiting for Something

HOW THE BRIGHTON BEACH RACES WERE CONDUCTED

NEW YORK, July 31—Sport lovers of the metropolis turned out 15,000 strong to see George Robertson and Al Poole with the Simplex to-night win the Brighton twenty-four hour race. The score was but 1,091 miles, eighty-six miles below last year's record. The Rainier, driven by Disbrow and Tund, after a steady and consistent performance, finished second, with 1,041 miles to its credit. The Palmer-Singer, another conservative, made 968 miles under the guidance of Howard and Lescault. The Stearns and the Lozier, after providing most of the excitement and fast driving, had to be content with fourth and fifth respectively, their scores being 919 and 885 miles. Fiat and Haynes did not finish.

Robertson was picked to win before the start, and was the popular favorite. After the Fiat met with an accident early Saturday morning he had a long lead over all the other competitors, and settled down to a steady grind. Had it not been for the exciting brush between the Stearns and the Lozier in the last few hours the race would have been very dull. But these two, although they had long given up all hope of winning set out to show a little speed, and succeeded beautifully. They lapped the leaders time and again, and drew forth the only real enthusiasm of the day.

Start and Progress of the 24-Hour Contest

The race began at 9:05 o'clock Friday night. The stands were crowded, and a solid row of automobiles lined the parking enclosure. In the glare of electric arcs and calcium lights it made a very picturesque and exciting scene, just the sort to attract the evening crowds at Brighton and Coney Island, as well as the more fastidious automobiling contingent. This was the line-up:

1—Acme, 60, Cyrus Patschke and H. A. Vantine.
2—Lozier, 50, Ralph Mulford and Harry Cobe.
3—Simplex, 50, George Robertson and Al Poole.
4—Blank.
5—Stearns, 30-60, Laurent Grosse and J. B. Marquis.
6—Palmer-Singer, 60, Ray Howard and Frank Lescault.
7—Rainier, 45-50, L. A. Disbrow and Charles Lund.
8—Fiat, 45, Ralph De Palmer and E. H. Parker.
9—Haynes, 36, Frank Swelgert and John Looney.

Robertson made the quickest start and took the rail on the first turn, closely followed by the Stearns, and held the lead for six miles. Then the Stearns drew ahead. Its time for the ten miles was 11:29 4-5. On the twenty-third lap it met with trouble and retired to the paddock, leaving the Fiat in the lead with Simplex second. De Palma made fifty-three miles in the first hour. About midnight the Stearns, which had returned to the track, met with the accident that put it out of the running. Marquis had just relieved Grosse at the wheel, and on his first lap, driving fast to catch up with the leaders, he took the turn into the homestretch at such speed that the car turned turtle. Robertson was just behind, and had to do some quick work to avoid running into the wreck. Neither Marquis nor Lang, his mechanic, was seriously hurt.

The Fiat had tire trouble at intervals, and finally hit a fence post, which strained the front axle. As it fell behind the Simplex drew further and further into the lead. On the tenth hour it was twenty-three miles ahead of the Rainier, now in second place, and fifty miles ahead of the Fiat. The Rainier was running steadily, but had not the speed to overhaul the red car. From this time on the race was featureless. In the afternoon the Acme came from the paddock after an extended vacation and did a little fast driving, but soon had to retire again.

By 5 o'clock in the afternoon the track was so badly cut up on the turns that the race had to be stopped while repairs were made. The management had advertised that the race would be run without intermissions, but they claimed that the police demanded that the track be put in better shape. The turns at each end of the homestretch had been worn into deep ruts, and the dust was blinding; the only part in condition for fast time was the backstretch. The intermission lasted an hour, during which the cars were kept "in control," and no working on them was permitted. The drivers, however, were glad of a chance to rest, and many of the crowd took the opportunity to get supper.

When the race was started again only five cars were in line. The Haynes had quit in the fourteenth hour with a broken crankshaft, and in the seventeenth the Fiat's damaged axle forced it to retire also. The Acme was in the paddock, but not officially out. Poole, now in charge of the Simplex, set a pace of about thirty-five miles an hour, and the Rainier and Palmer-Singer, who now were sure of second and third places respectively, followed him. This was good generalship, but not calculated to please the crowd. The Stearns, however, gallantly started to furnish some excitement, and in this entertaining effort it was soon joined by the white Lozier. In the darkness the two tore around the track at real racing speed, repeatedly passing the trio of conservatives and drawing hearty applause from the grandstand.

In spite of the fact that the prices had been nearly doubled over last year, a big crowd of Saturday evening pleasure seekers turned out, and by 8 o'clock the capacious grandstand was full. Automobiles occupied all points of vantage and kept up a continuous honking. The track was well illuminated, and the racers with their glaring headlights made a fine spectacle. The performance of the Lozier was particularly impressive. Both car and drivers were garbed in dusty white, giving it a ghostly look as it swept past the stand; and then the dark Stearns with its roaring exhaust furnished the right contrast.

When only a quarter of an hour remained Robertson again took the wheel of the Simplex and undertook to win a share of the applause. He reeled off some fast miles, and by his example aroused the Rainier and the Palmer-Singer, so that at its finish the race was quite exciting.

Friday's Preliminaries Had Several Smashups

The usual preliminary events on Friday afternoon furnished several accidents. The first race, for motorcycles, had hardly started when Fred Voelker, on his 7-horsepower N. S. U., made a dive through the canvas fence on the turn into the homestretch. A moment later Edward Seery, also on an N. S. U., went through the same hole and bumped into Voelker. Both drivers were bruised and scratched.

The 100-mile Marathon saw the only broken record of the meet, Lorimer's time of 1:52:00 3-5 being over a minute under the mark set by Clemens and a National. Soon after the start of this race the Midland skidded through the fence on the dangerous turn into the homestretch. The crew escaped injury, and the car was patched up in time to re-enter the race and take third place. The Kisselkar and the Acme, the only other competitors, had tire trouble and withdrew. The mile and five-mile time trials were slowed down because De Palma, the principal competitor, was saving his car for the twenty-four hour race.

William Pickens, the manager of the Buick racing team, protested the action of the Motor Racing Association in limiting the 100-mile and twenty-four hour races to cars costing over $2,000, thus barring the Buicks. He said that the whole Buick team, with two cars, was in New York, and would have entered both these races if they had been permitted. Certainly entries were sadly needed. Of the sixteen cars, which, it had been predicted, would start in the twenty-four hour race, only eight appeared, and most of the time half of these were in the paddock. If the entry list had been full, the track could never have stood the wear. Unless some strenuous measures are adopted, the next twenty-four hour race will have but scant support.

Later the M. R. A. announced that the next twenty-four hour race would be held August 27-28, and further said that fourteen entries had been pledged, mostly by members of the association. Summaries of the various events follow:

Ten-Mile Motor Cycle Handicap—Won by Stanley Kellogg, Merkel; time, 10:16 2-5; J. F. McLaughlin, N. S. U., second; F. B. Baker, Indian, third.

Mile Time Trials—Ralph De Palma, Fiat; time, 0:54 3-5; Louis Chevrolet, Buick; time, 0:58 2-5; Charles Bowers, Red Dragon; time, 1:06 4-5.

Fifty Miles, Cars $1,251-$2,000—Won by Louis Chevrolet, Buick; time, 59:39 2-5.

Five Miles, Free-for-All—Won by Ralph De Palma, Fiat, 5:51 3-5; Charles Bowers, Red Dragon, second.

Five Miles, Cars $851-$1250—Walkover for E. M. F.

Brighton Marathon, 100 Miles, Cars $2,001-$3,000—Won by Lee Lorimer, Chalmers-Detroit; time, 1:52:00 3-5; John Juhasz, S. P. O., second; W. O. Stokes, Midland, third.

TABLE SHOWING PROGRESS OF THE RACE AND STANDING OF COMPETING CARS AT END OF EACH HOUR

Car	Hours—1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24

PRESIDENT MAY FIND RACES MORE ATTRACTIVE THAN GOLF

LOWELL, MASS., Aug. 2—Although President Taft has not yet been able to definitely signify his acceptance of the invitation of the Lowell Automobile Club to be its guest at the big race meet, to be held over the Merrimac Valley course, during the week of September 6, the specifications for the main grand stand that is to be erected call for a Presidential box in front of the main pavilion. They also show the 100 boxes that will occupy the lower part of the stand, and beyond these boxes will be arranged seating capacity for 5,500 spectators. Other stands will be erected along the course.

The stands for the judges, the press and the musicians will be erected on the opposite side of the course, and connected with an overhead bridge to the main stand. A special bridge will be constructed over Dunbar avenue and above the course, to permit entrance and exit after the races have been started. The Boston & Maine Railroad and the Boston & Northern Railway parallel the course, but upon the opposite side of the Merrimac River. In order to give direct transportation, the War Department has been asked to sanction a plan for erecting a pontoon bridge, the river being United States waters. The total cost of running off the program is estimated at $50,000, exclusive of the Vanderbilt Cup race, provided it should be decided to run that race over this course.

The Lowell carnival will be officially opened on Saturday evening, September 4, with a banquet by the Lowell Automobile Club, at its new club rooms, which occupy one entire floor in the Richardson Hotel. The racing program, as arranged by days, is as follows:

Monday—250-mile road race, for light stock cars.

Tuesday—Mile straightaway records.

Wednesday—318-mile race, for large stock cars.

Thursday—Athletic events.

Friday—Motorcycle races under F. A. M. rules.

The course is now undergoing a thorough oiling, and the back stretch, which last year was rough in spots, is rapidly assuming track smoothness under the combined labors of 250 workmen. The course will be guarded by a military patrol, and a complete telephone system will connect all points of the circuit. Every precaution will be taken to insure the safety of both the contestants and the public.

FOREIGN CARS ELIGIBLE IN FAIRMOUNT PARK RACE

PHILADELPHIA, Aug. 2—After thoroughly considering the question from every angle, the contest committee of the Quaker City Motor Club, under whose auspices next October's 200-mile Fairmount Park stock chassis race will be run, has decided to accept foreign cars as entrants, with the proviso that they be owned by Americans. The committee was about evenly divided as to the advisability of this action, but when the fact was emphasized that the exclusion of foreign cars would be attributed by some to a fear of the result, the "antis" flopped over in a body, and the final vote in favor of their admission was practically unanimous.

The race will be run on Saturday, October 9, probably in the afternoon. Twelve hundred of Philadelphia's "finest," with miles of rope, will furnish a replica of the course-guarding which so surprised and delighted visitors last year, and set a standard in this respect which other race promoters have vainly endeavored to equal.

Mayor Reyburn, who, with Frank B. Hower, of the A. A. A., has been named as honorary referee, is intensely interested in the affair, and is devoting no little time to perfecting the details. The committee which will represent the club in its dealings with the representatives of the charitable institutions which will participate in the distribution of the receipts consists of Frank Hardart, Sr., Chairman; Fred. C. Dunlop and William J. Donnelly.

Not only will the Quaker City Motor Club not benefit financially from the sale of parking spaces, seats, etc., but the club has asked for the reservation of fifty parking spaces at the rate decided upon by the beneficiary institutions' committee, and a check therefor will be sent to the proper person as soon as the Mayor names the committee.

The contest committee finally decided on the disposition of the $5,000 cash (or plate, at winners' option) which will be distributed among the first four cars to finish, as follows: $2,500 to first; $1,250 to second; $750 to third; $500 to fourth. In addition, there is also heard from some of the public-spirited "laymen" who have already become deeply interested in the race and its charitable feature, a suggestion that additional enthusiasm might be aroused by newspapers, prominent business concerns and others hanging up trophies for fastest lap, consistent running, best tire record, etc. This suggestion has already been acted upon and there will be at least two such trophies in addition to the $5,000 in "frigid gelt" which the club has hung up.

On Saturday, just one day after the entry blanks were mailed, Secretary Harbach received the first entry—that of an Acme car with Malin Leinau nominated as the driver.

Start of the "Water Rats" from Charing Cross, London, for Brighton

LONDON, July 24—While the Paris Salon will not be held this year, the Olympia Show will take place in November, as usual, and judging from present indications, a most successful show it will be. Improvements have been recently made in the building, with the result that there will be room for over 150 stands on the ground floor, as well as the accessory exhibits in the galleries. The whole of the available space has been applied for, and there seems to be no doubt that Olympia will be the business center of the European automobile trade for the coming winter.

The Grand Order of Water Rats, some 300 strong, went down to Brighton Sunday, the 4th, on a hilarious automobile trip. This order, it may be well to explain, is composed not of rodents, but of members of the "profession"—theatrical; a Good Samaritan free masonry, with a rare capacity for enjoying itself. The order assembled 68 cars, and after a headlong dash for the seashore, lunched at the Metropole with much merriment and speechmaking. Harry Tate, whose comic struggles with a refractory automobile convulse the vaudeville audiences, acted as marshal, and Fred Ginnett, as King Rat, had a huge gray "property" rat perched on the hood of his car.

The headlight trials of the R. A. C., which were held last week, attracted a number of entries, and although the results have not yet been published, there is reason to believe that they will be very interesting to automobilists. Special prominence is given in the rules to the reduction of the dazzling effect, about 36 per cent. of the total marks depending on this feature. For effectiveness of illumination 54 per cent. is set apart, and the remainder goes to practical and mechanical considerations. All the acetylene jets, electric bulbs, etc., were previously tested to find the amount of light available; the trials determined what part of this was effectively used in service. The photometer test was held in the Crystal Palace grounds on Monday and Tuesday evenings. American makers were represented by the Badger Brass Company and Rushmore Lamps, Ltd.

The R. A. C. itself is steadily increasing in numerical strength, and the total of members, ordinary and associated, is over the 16,300 mark. The number of associated automobile clubs is over 96 and still increasing.

A SCHEME FOR INTERNATIONAL TOURING RECIPROCITY

PARIS, July 28—Europe has a scheme in hand which, if carried to completion, will make touring through her various countries a matter of less formality than motoring through the various states of the Union at present. Under present regulations it is necessary to have as many driving licenses, as many registration numbers, and pay as many entry fees as there are countries in which you desire to travel. If the new scheme is carried through, a driving license issued by any European country will be recognized in every other country; a car registration in one land will be good for all other lands; finally, the deposit of one sum will procure an international triptyque, admitting to all European countries, the sum being returned on the car's return to its native country.

America has as much reason to be interested in the scheme as Europeans, for her citizens form a very respectable percentage of the international tourists who skim over the highways of France, Germany, Italy, England, Holland and Austria. Curiously, however, America is the only nation that is out of the scheme; it is more than probable, however, that she will shortly be admitted.

The idea of simplifying touring regulations originated in Germany in 1907, the German authorities suggesting to the French that as they were at the head of the automobile movement they should call a conference of the leading powers to deal with the subject of international regulation. The French government accepted the proposal, and in due time invited government officials of other countries to meet her and talk over this subject. Other nations became interested, asked to be admitted, and were admitted, with the result that the proposed conference was postponed on several occasions. Now every nation in Europe, without a single exception, is enrolled in the scheme, and should have met in Paris this week, at the Ministry of Foreign Affairs, had not Belgium and Holland asked for a postponement, which was granted, the revised date being October 5.

Three main points will be brought before this meeting of the nations. It will be proposed that the driving licenses of any nation shall be accepted by all other nations. At present most European countries issue driving licenses only after a practical examination. The exceptions are Belgium, which has no special regulation, and England, which, like New York State, is only interested in receiving the registration fee, and does not care a rap about the applicants' ability or otherwise to handle a car. France will accept the British Royal Automobile Club's certificate and the Motor Union's license as proof that the holder can drive a car, but, of course, will not accept the British government's license. Germany will accept the French license providing it is endorsed by a German consul, but not otherwise. An American driving license would not be accepted anywhere in Europe.

After each nation has put its house in order and instituted a driving license issued only after examination, as in France, Germany and Italy, it is proposed that such license shall be recognized by all the countries of Europe without further examination or formality. Here America is directly interested, for a tourist who is going to "do" the Continent would only have to obtain one license for all the countries he intends to visit. If America comes into the scheme, even her license may be recognized by European countries.

A similar arrangement is proposed regarding registration numbers. At present, if driving in France you must carry French numbers, though you are not called upon to pay French fees. If you tour in England you must carry English numbers and pay full fees whether your stay is one of six hours or six months In Belgium you hook on that country's number in addition to your own. In some other countries the customs officers give temporary numbers that must be attached and maintained while touring in that country.

The object of the conference is to devise a scheme whereby one registration number will be accepted all over Europe. It is not a difficult task, providing each of the contracting parties will undertake to look after the few black sheep that are to be found in every community. Here again America is directly interested, for whereas a United States number is sometimes admitted to be used in France for a short period—the holder being given a certificate to that effect to save trouble with the police—under the new scheme such a number would always be admitted, not only in France, but in all European countries.

The question of an International Automobile Passport, as suggested by the Touring Club of Italy, is even more important Under the old method of touring it was necessary to deposit the duty on a car on entering the country, the amount being returned on leaving. The result was that plenty of gold had to be carried in the coinage of the land the motorist was about to enter, and there were long delays when leaving the country, for unless the station was an important one the officers never had the amount of cash on hand. This, of course, was repeated for every country visited. At the present time the automobilist can deposit the customs duty with the Touring Club of France, and various other organizations, even before leaving his home land, receiving in return a triptyque which admits him free and without formality. A separate triptyque must be returned for each country about to be visited, and separate fee deposited, the amounts being returned either at the central office or through the holder's banker at home.

Under the Italian Touring Club's scheme there would be but one triptyque for the whole of Europe, the amount to be deposited being that of the country with the highest duty. This amount would be deposited with the home authority on issuing the triptyque, and only returned when proof had been given that the car had been brought back to the country of its origin. In the meantime it might pass through half a dozen different countries without depositing a cent.

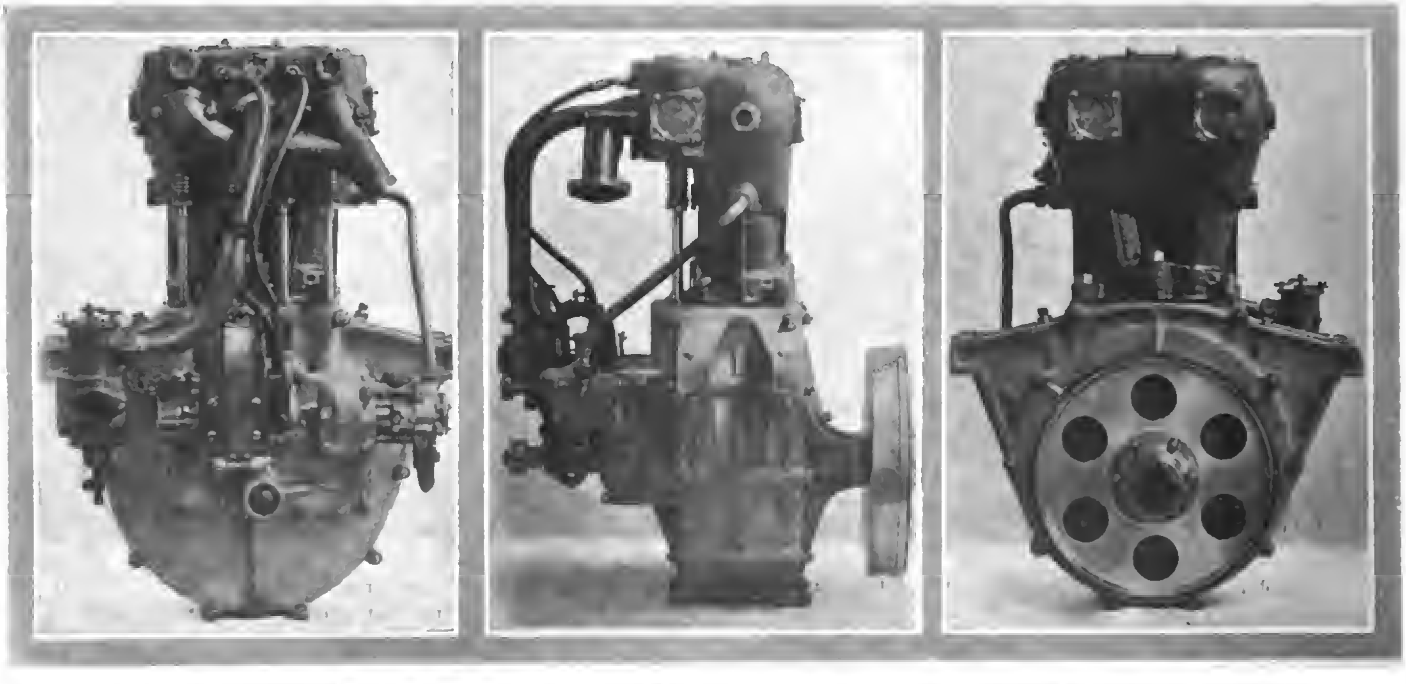
This scheme also interests Americans more than any other nation, for they travel in more different countries than the average European, who, as a rule, is content to confine his operations to one land at a time. The scheme, bold as it is in the eyes of red-tapeism, does not present any serious difficulties of realization.

The important point about the conference to meet in the Fall is that it is not composed of delegates from automobile and touring clubs, limited to the expression of their ideas on what should be done, but is made up of official delegates appointed by the various governments, having power to vote in favor of any practical scheme. Automobiling is growing to such an extent that it is fast breaking down the artificial barriers which have existed in old Europe for generations.

TWIN CYLINDER OF FRENCH PRODUCTION

Paris, July 21—More than local interest attaches to the new Lion-Peugeot two-cylinder motor from the fact that it is the direct outcome of the limited bore race regulations enforced in Europe for the last two years. The firm, in common with such others as Sizaire-Naudin, Delage, De Dion, Werner, etc., has specialized in the one-lunger, and has indeed never previously built an engine with multiple cylinders. For the present racing season three cars were experimented, two of them having one cylinder only, of 3.9 inches bore by approximately 10 inches stroke, and the third a twin cylinder in V. Out of three races the twin has been victorious in two, and finished with second place in the third one. Doubtless with their abnormal stroke and immense valve—three inlets and three exhausts for one cylinder—the singles were a trifle faster than the twin, but this latter possessed such qualities that the firm felt justified in adopting it as their standard model for next season.

The two cylinders are in a single casting, and are only very slightly inclined, the angle from the vertical being 20 degrees. They are set across the frame, and not lengthwise, as in the standard vertical twin cylinder engine, the valves, magneto, carbureter and pumps being in front. This construction allows of an engine so compact that it can be mounted on the same chassis as the one-lunger without any changes whatever. The



As seen from the front — A view from the side — As seen from the rear

Lion Peugeot Two-Cylinder Motor Which Has Created a Sensation in European Racing Circles crank case is of the single-cylinder type; that is, it is divided vertically, the two halves being united hy horizontal bolts. Interior flywheels are employed, with a built-up crankshaft, as in the singles, the two connecting rods being attached to one pin, one of the rods fitting on direct, while the other has a forked end.

Although the cylinders are inclined, the valves are vertical, and are all in one line, as will be seen from the illustration, at the front of the engine. The two exhaust valves are at the outside, while the two inlets are together in the centre. A single camshaft operates all the valves, and is fitted with a couple of supplementary sliding cams for relieving the compression in order to facilitate starting. A pinion on the camshaft meshes with a pinion on a secondary shaft, on which are mounted the magneto and oil and water pumps. The carbureter is also at the front of the engine and to the left of the magneto, in a thoroughly accessible position. There is a single length of intake piping for the two cylinders, entering the intake manifold cast with the cylinders midway in the block. As this "buried" manifold is heated by the circulating water, the mixture is warmed before entering the cylinders, thus avoiding any necessity for jacketing the carbureter.

One of the most interesting features of the engine is the ratio of bore to stroke. On this motor the cylinders are 75 by 150 millimeters (approximately 2.9 by 5.9 inches), which is a ratio of two to one. Certainly but for the experience gained in the limited bore races, such a long stroke would never have been adopted on a standard pleasure car. On their present single-cylinder models, indeed, Lion-Peugeot employs a "square" engine of 110 by 110 bore and stroke. The experience with their racers, where the stroke was carried up to a value two and a half times that of the bore, has led them to adopt the long-stroke engine for pleasure car models. This model would also appear to indicate a tendency to break away from the single-cylinder model which has been so strongly developed in France during the last two or three years, and has been brought to a wonderful degree of efficiency, making it far removed from the noisy spasmodic creations of a few years ago. There is now practically only one firm of importance producing single-cylinder engines only. On the other hand, there is hardly an important firm in existence in France which does not build, if not one-lungers, at any rate some two-cylinder engines. In the few cases where large four-cylinder engines are alone produced it is because of innate conservatism of the management, or for financial reasons that the company would not care to make public.

NEW FIRM GETS LARGEST TRUCK ORDER

Worcester, Mass., Aug. 2—Probably the largest truck order ever placed was that which General Samuel Pearson, representing the American-South African Commerce Company, Johannesburg, has just given the newly-formed R. L. Morgan Company, of this city. This is for 100 trucks, to cost $3,500 apiece, and be delivered, 20 per year, until the contract is filled, if it is not increased in the meantime. The first car is to be delivered on September 1 to the company, which conducts an immense mining and development business in South Africa. The trucks will be used for hauling ore and supplies to and from the mines. Previous to placing the order, the company's representative, General Pearson, known to fame as the Boer army purchasing representative, journeyed from the American headquarters, at Allentown, Pa., to the factory in Worcester, which latter was inspected in detail.

SIXTEEN AUTOMOBILES IN A SEWER

Baltimore, Aug. 2—Every day sees another most novel use for the automobile, and a "stunt" pulled off here lately ought to rank among the very novel. This was on the occasion of an inspection of the city's new trunk sewer. Preceded by Mayor Mahool in a Winton, no less than sixteen automobiles made the six-mile trip, the way being lighted by powerful searchlights.

WHEN A TIRE SHOULD NOT BE RE-TREADED

Chicopee Falls, Mass., Aug. 2—That 90 per cent. of the old tires that are re-treaded ought not to be, as far as the owner's interests are concerned, is the opinion of one of the Fisk Rubber Company's experts. An autoist may have a casing that has given him a few thousand miles of good service and is still apparently in good condition. He consults the manufacturer of the tire in regard to having it re-treaded, and is advised against it, on the ground that the inner fabric is weakened. The autoist, unheeding, goes to some alleged tire expert, who perhaps has served a few months in a garage before branching out in business for himself, and is told that the company is all wrong. When this repairer does the job, as a rule only the cheapest quality of scrap rubber is used and the crudest methods employed. Should the re-treaded tire last only a week or so, the autoist has no redress from the repair man, who does not guarantee his work, and coolly says, too late, that the tire "was no good in the first place." He has no reputation to lose and is not greatly worried.

The great essential point in the life of a tire is proper inflation. Users of Fisk tires who have driven them 5,000 miles or so properly inflated, frequently bring them back for re-treading, and in this case a serviceable job is possible and the tire will be good for a few thousand miles more. But if a tire has not been driven at the proper degree of inflation, it is almost certain that the fabric has been so strained that re-treading will be useless. A real expert knows what to advise in such cases. The ordinary garage or repair man goes ahead and re-treads, anyway—and collects for it.

MAXWELL TRANSCONTINENTAL TRIP ENDS

San Francisco, Cal., Aug. 2—After just 35 days of touring Mrs. John R. Ramsay, of Hackensack, N. J., drove her Maxwell car into San Francisco, completing the first transcontinental automobile trip ever made by a woman. Not only did Mrs. Ramsay successfully make the tour of nearly 4,200 miles, but she drove the car from start to finish, made all adjustments and changed the tires when necessary. From Laramie, Wyo., where their progress was last reported, the going was bad. Deep washouts, long since dried, some of them 10 or 12 feet deep, had to be traversed. When Salt Lake City was reached on July 19 a sight-seeing trip of several days was enjoyed by the ladies before resuming the journey westward. In some respects the trip to Reno, Nev., was the hardest part of the tour, for in addition to the hard climbs over the Sierra Nevada mountains, made doubly hard by the rough roads and underbrush, much loose shifting sand was met with. From Reno to Sacramento, Cal., there were some rather stiff grades to climb, but once in sight of San Francisco and the Golden Gate all difficulties were forgotten.

STEP TAKEN TO CHECK PRICE-CUTTING

Buffalo, N. Y., Aug. 2—Pursuant to their announced intention of reducing the objectionable price-cutting habit to its lowest possible terms, the Weed Chain Tire Grip Company, of New York City, announce that they have secured a restraining injunction in the Federal Court of the District of Western New York against the International Automobile League of Buffalo from selling Weed chain tire grips or parts thereof at lower prices than those marked on the bags containing the grips, or upon the Weed price-list.

The Weed people are the first to make successful fight against the International Automobile League, and their victory should receive the endorsement and support of every fair-minded motorist and accessory dealer. They have been uniformly successful in insisting upon fair business methods, have been pioneers in the struggle for the maintenance of prices, and their victory not only protects the trade in general, but makes for the betterment of every one interested in the automobile industry. Although price-cutting as a rule is objectionable, it must be admitted that many automobile accessories are listed at exorbitant prices.

WESTERN AUTOMOBILE BLUE BOOK

This week Volume IV of the Blue Book series, broadly covering the Middle West, is issued by the Automobile Blue Book Publishing Company, of New York and Chicago. Its routes begin at Buffalo and extend in a general way to the Mississippi and Missouri rivers.

By a far stretch this is the largest and most important route compilation ever attempted west of Pittsburgh, and the through lines of the route contain 20,800 miles of routes, nearly all of which were covered in the spring and early summer by the Blue Book cars. For every mile of travel, odometer measurements have been taken, and other data sufficient to enable the locally unacquainted tourist to travel the entire territory without trouble.

It is now possible for the owner of the Blue Books to leave almost any point in New England, New York State, Pennsylvania or New Jersey, and travel to Cleveland, Columbus, Cincinnati, Louisville, Indianapolis, Chicago, Detroit, Grand Rapids, South Bend, Madison, Wis.; Peoria, Galesburg, Davenport, Clinton, Cedar Rapids, Omaha or St. Louis, with facility. To further assist the tourist, 124 route maps and 79 city maps illustrate the 174 different routes. For the first time a general map has been made, giving in their proper geographical relation the main-traveled routes of Ohio, Indiana, Michigan, Illinois and portions of Kentucky, Wisconsin and Iowa.

By means of numbers placed clearly on the routes, it is possible for the user to find almost any route desired with a minimum of inconvenience, while initial and terminal points are cared for by an extensive "index of places."

The Automobile Blue Book Publishing Company has opened permanent headquarters at 1200 Michigan avenue, Chicago, where the full series of Blue Books will be kept permanently on file. They can also be had of the leading hotels, garages and booksellers in the principal cities, or from the Eastern office of the publishers, 239 West Thirty-ninth street, New York City.

BLUE BOOK ABSORBS N. E. RED BOOK

An important deal was consummated last week, when the publishers of "The Official Automobile A. A. A. Blue Book" purchased outright the entire route book and map business of F. S. Blanchard & Co., of Worcester, Mass., publishers of the "Red Book Automobile Guide of New England" and the "Pilot Maps." The "Red Book" will be consolidated with the New England section of the "Blue Book," and the information heretofore contained in the two volumes will hereafter be given in one.

Henry MacNair, the well known typographer, who prepared the routes and maps for the "Red Book," has joined the staff of the "Blue Book," and will continue his work in New England.

Tuesday of this week the New England road crew, consisting of E. R. Mixer and Mr. MacNair, started on the work for the "1910 New England Blue Book." Next week John Mixer and Robert Bruce will start in car No. 2 through New Jersey and the South, and car No. 3, in charge of John P. Dods, will leave Chicago to begin its work on the "1910 Middle West Book."

"El Toro: A Motor Car Story of Interior Cuba"—This is a story that is worth the reading, for, though it is written by E. Ralph Estep, advertising manager of the Packard Motor Car Company, and tells of a trip in a car of that make, the writer has not yielded in the least to the temptation to exploit the particular automobile in which he is naturally most interested.

Hence, he tells his story of Cuba brilliantly and interestingly, and it gives one the desire to tour in the "Gem of the Antilles." Of course, the book is profusely illustrated, and since no price is mentioned in its publishing, it is more than probable that the Packard Motor Car Company, Detroit, Mich., is prepared to supply a limited demand to those who may take the trouble to write and ask for the book.

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

Aug. 5-7.........Chicago, Midsummer Meeting Society of Automobile Engineers.
Sept. 21-23.......Cleveland, Good Roads Convention, American Automobile Association.
Nov. 6-13........Atlanta, Ga., Auditorium-Armory, National Automobile Show.
Dec. 31-Jan. 7....New York City, Grand Central Palace, Decennial International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
Feb. 5-12.........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.

Races, Hill Climbs, Etc.

Aug. 5...........Chicago, Fourth Annual Algonquin Hill Climb, Chicago Motor Club.
Aug. 7...........Richfield Springs, N. Y., Hill Climb, auspices of the "Earlington."
Aug. 26-27.......New York City, Brighton Beach, 24-Hour Race. Motor Racing Association.
Aug. 26-28.......Minneapolis, "Little Glidden Tour," Minnesota State Automobile Association.
Aug. 19-21.......Indianapolis Motor Speedway, First Race Meet.
Sept. 6-11........Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
Sept. 10-11.......Baltimore, 24-Hour Race, Motor Car Racing Association of Maryland.
Sept. 15..........Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Sept. 21..........Riverhead, L. I., Long Island Derby, Motor Contest Association.
Sept. 21-29.......Washington-Boston and Return, Munsey Reliability Run.
Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City M. C.
Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.
Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

FOREIGN

Races, Hill Climbs, Etc.

Aug. 22-29.......France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Aug. 24-29.......Belgium, Circuit des Ardennes, and Coupe de Liedekerke, Belgium Automobile Club.
Sept. 5...........France, Mont Ventoux Hill Climb.
Sept. 19..........Austria, Semmering Hill Climb.
Sept. 22..........Austria, Coupe Rochet-Schneider.

WASHINGTON-BOSTON PATHFINDER AT IT

WASHINGTON, D. C., Aug. 2—With entries coming in rapidly and the work of mapping out the route under way, the Munsey reliability contest is beginning to take definite shape. The following entries have been received during the week: Walter Cram, Mitchell; Carter Motor Car Corporation, Cartercar; Lambert Automobile Company, Maxwell; Olds Motor Works, Baltimore branch, Oldsmobile. This brings the total up to eleven.

The Chalmers-Detroit pathfinding car left Washington last Friday with the following party on board: Karl Schnorr, driver; Thomas S. Rice, George Deatel and D. E. Taylor. Rice will write the pathfinding stories, Taylor will do the picture work, and Deatel will arrange for hotel accommodations, gasoline supplies, etc. The pathfinders were given a great send-off. Before the start President Taft received them at the White House and was given a brief history of the car's achievements.

Charles J. Glidden, in a telegram to the managers of the tour, said: "I wish to extend my congratulations to Mr. Munsey for arranging a tour of this character, which will be of unusual interest. You are sure to have a large number of entries and can expect some from this tour after its finish in Kansas City."

AUTOMOBILE ENGINEERS MEET AT CHICAGO AUGUST 5

THE annual meeting of the Society of Automobile Engineers will be held at Chicago, August 5, 6 and 7, with headquarters at the Illinois Athletic Club, whose hospitality has been extended to all members of the society, with attending advantages. such as rooms for the members and living facilities. Members of the S. A. E. who are members of the I. A. C. will be the guests of F. J. Newman, chairman of the local committee of the S. A. E., and this, together with other calculating preparations at the hands of a very active local committee, must, as a natural sequence, result in an enjoyable visit of the members of the society.

Among other events of interest, to act as a magnet in drawing a large attendance, will be the annual hill climb, known as the Algonquin. This event will fall on August 5, and provision has been made for all members who may care to enjoy the ride. On Friday, when the members will be back from the hill climb, serious business and a fine selection of papers of a technical character will be presented. Visits to the shops of the industry in that locality will be made, and entertainment of a varied character is promised.

The society, now a four-year-old, has grown and prospered; its doings are heralded as of the greatest importance to the industry, and the membership is composed of the engineers and associates, who are largely responsible for the growth and stability of American-made automobiles. That there is a great advantage attending the Association of Automobile Engineers on a neutral basis is self-evident, and when standardization of parts is taken up at greater length it must be done under the direction and authority of just such a body, independently of any taint of trade affiliations.

That there is a demand for a society such as this is proven by the events in its history, dating from the struggle of its first president, A. L. Riker, whose privilege it was to wrestle with inertia which is bound to influence any new movement; after two years, Mr. Riker handed the reins to Thomas J. Fay, who, as second president of the society, held four meetings during that year and inaugurated a campaign of membership, ending in quadrupling the same. Henry Hess, the third and present holder of this important office, brings to bear a wealth of administrative ability and a zeal which promises to break all bounds. The committee work is in the hands of a band of workers of whom it may be said that failure is wholly unknown. The committee assignments, as promulgated by President Hess, are as follows:

Meetings—H. M. Swetland, chairman; H. E. Coffin, David C. Fergussen, A. L. McMurtry, F. J. Newman.

Finance—H. M. Swetland, chairman; B. D. Gray, W. S. Gorton, W. R. Wall, R. H. Whiting.

Membership—F. J. Newman, chairman; H. G. Chatain, James H. Herron, J. C. Perrin, John Wilkinson.

Publication—Prof. Rola C. Carpenter, chairman; H. F. Donaldson, Charles E. Duryea, E. A. Rutenber, E. T. Birdsall.

Papers—Prof. Rola C. Carpenter, chairman; H. F. Donaldson, Charles E. Duryea, C. B. Hayward, Herbert L. Towle.

Library—H. G. Chatain, chairman; Herold B. Anderson, J. M. Elsworth, Henry Souther, F. B. Stearns.

House—H. E. Coffin, chairman; A. C. Bergman, A. J. Moulton, Henry Souther, G. A. Wells.

In view of the large attendance, by the large Eastern contingent, the members concluded to engage a special car on the Twentieth Century Limited, over the New York Central & Hudson River Railroad, which left the Grand Central Depot at 3:30 P. M., on August 4. This contingent included many members from New England, although members from Boston, Worcester and vicinity preferred to go by a more direct route, by way of Albany. Buffalo is also well represented.

GOOD ROADS DELEGATES TO MEET AT CLEVELAND

CLEVELAND, Aug. 2—The large amount of road construction which is being done near this city gives it many advantages as a meeting place for the second annual National Good Roads Convention, which will be held here September 21-23 under the auspices of the American Automobile Association, the National Grange, the U. S. Office of Public Roads and the American Road-Makers' Association. The work of the convention in Buffalo last year attracted much attention among automobilists and engineers, and it is expected that as a result the delegates this year will be more numerous and more representative.

F. A. Pease, chairman of the Demonstration Committee, has made out a tentative plan of the exhibits of practical road work, and is now preparing a map of the city showing the different localities selected. Examples of almost every known sort of road construction are included.

East of Cleveland Heights the County Commissioners are building a brick road, the brick being four inches deep and laid on a four-inch concrete base, between Portland cement curbs that are molded in place. This stretch is about four miles long, and during the convention may be studied in all its stages, from sub-grading to completing the finished surface. Through the same village a new macadam road is being built, the surface being trap rock three inches in depth laid on a twelve-inch limestone telford base. Another extensive improvement is being made on Euclid Boulevard. Here the foundation is nine inches in depth, of crushed limestone, the surface to be filled with asphalt or coal-tar sufficient to render it impervious to water.

An illustration of economical work will be seen on Lee Road. The construction consists of six-inch blue sandstone, hammer-broken, and placed on the sub-grade as closely as possible. Stone screenings are scattered over the surface and thoroughly flushed in before rolling. After the sandstone is compacted a four-inch wearing surface of blue limestone is rolled on, the top layer being filled with coal tar as the work progresses. The cost of this construction is about 70 per cent. of that of the trap-rock roads.

The committee is also planning to give a very thorough illustration of culvert work, and A. Felgate, the Bridge Engineer of Cuyahoga County, will read a paper dealing with their construction. Examples will range from 36-inch box culverts to a magnificent concrete arch of a span of 280 feet now being erected over the Rocky River, west of Cleveland. Another question that will be taken up is that of the testing of materials, and the committee will emphasize the necessity for the careful inspection of such materials while also illustrating the methods by which accurate tests may be made.

The committee in charge of the tests and demonstrations includes, besides F. A. Pease, the chairman, L. W. Page of the Office of Public Roads, Washington, D. C.; J. C. Wonders, State Highway Commissioner of Ohio; Col. W. D. Schier, State Highway Commissioner of Massachusetts; Robert Hoffman, City Engineer of Cleveland; A. B. Lea, Engineer of Cuyahoga County; W. A. Stinchcomb, Park Engineer of Cleveland; G. T. Barnesley, Road Engineer of Alleghany County, Pa.; William Dilger, Detroit, Mich., Superintendent of Parks, and H. H. Johnson and E. A. Merritt, of the Cleveland Automobile Club.

Capitalist Edwards Delivers Deed to Manager Morris

Climax of the ceremonies attending the breaking of the ground for the new factory of the Model Automobile Company, at Peru, Ind., which will be devoted exclusively to the manufacture of Great Western automobiles.

MODEL BREAKS GROUND FOR NEW PLANT

PERU, IND., July 31—Wednesday was a big day for the industry in this city, as it was the day set for breaking ground for the new factory of the Model Automobile Company, makers of Great Western cars, which will total in length some 470 feet. The occasion took the nature of a civic holiday, and the parade was under the auspices of the Automobile Club of Peru. All makes and styles of autos were in the procession, but all paid courtesy to the home concern by carry streamers bearing the legend, "Great Western Building Celebration," and proceeded to Oakdale, the suburb where the new factory is to be located. A large platform wagon served as a stage for the ceremonies, which took place at three o'clock in the afternoon and consisted of songs by the Model male quartet, speeches by C. Y. Andres, president of the Commercial Club, and A. L. Bodurtha, vice-president of the Model Automobile Company; presentation of deed and abstract to ground, by R. A. Edwards, president of the Oakdale Improvement Company, and acceptance by E. Mack Morris, general manager of the Model Automobile Company. The first shovelful of dirt was turned by R. H. Bouslog, secretary and treasurer of the Model Automobile Company. Max Kraus officiated as chairman of the meeting, and the exercises were concluded with the national anthem by the Third Regiment band. Light refreshments were served to the crowd, the Model people acting in the capacity of hosts.

Model Automobile Company Using Tents to Finish Cars

So pressed for space have the makers of Great Western automobiles become that it was necessary during the past month to erect tents to carry on the construction work during the erection of the new plant.

REGAL FINDING GOOD ROADS IN WEST

RAWLINS, WYO., July 29—Good is the best word to describe the condition of the roads as the Regal transcontinental plugger is finding them West of Denver. Leaving there after a very hearty send-off, and on a perfect day, the trip to Greely, 57 miles out, was made in excellent time. The course pursued took the car over the course of the annual Rocky Mountain Endurance run. Not contented with Greely as a day's work, the run was continued to Pierce, a boom town, and beyond that to Carr. The riding between the last two towns was the best by far that has been encountered thus far.

North of Carr and approaching the Wyoming line, the country suddenly broke into a series of small, sharp, steep foothills. The road surface continued so good, however, that the first hundred miles out of Carr were traversed in three hours and three minutes. Just beyond this darkness fell and the car was obliged to "creep" into Cheyenne, having no gas tanks.

Thursday morning found the car facing the first real climb to the summit of the Great Divide, the day's program being something like 6,000 to 8,000 feet of climbing to be done in 14 miles. With a bright day, cold sharp air, and continued good roads, the "stunt" was accomplished before noon, a lucky shot from the tonneau near the top bringing down the first game, a wildcat. After a short stop to inspect the Ames monument erected at

Home of the Guide That Showed the Regal the Way

This shack is located on the plains about 50 miles from Denver, and is the home of the guide that escorts tourists across the desert stretches where the road is hard to follow.

the Divide by the Union Pacific Railway, the tourists pursued their onward course to Laramie.

This was reached in a short time, because mostly down grade, the trip down being characterized by but one incident, that of losing the road. Little time was lost in finding the trail, however, and the day was closed with a fast run into Rock River.

Starting early the next morning from Rock River, trouble was also met very early, the car accompanying the pluggers being found three miles West, hopelessly sunk into an irrigating ditch. With the aid of block, tackle and stout manilla line, the car was quickly extricated, and they went on their way rejoicing that the pilot was on hand to direct them to the right roads. With this aid, six hours of hard work saw them into Medicine Bow, where the night was spent.

To-day saw the long fight lasting from Medicine to Rawlins, 60 miles. Noon found them at Hanna for dinner, and beyond that, the Union Pacific had to be crossed, two hours being lost. Fort Steele was reached at 3 p. m. and finding the bridge down, it was necessary to cross on the rails and ties of the Union Pacific steel bridge. Permission had to be obtained first, which lost them several valuable hours. This having been obtained with only the loss of time and temper, the car proceeded to bump its way across the river on the ties of the railroad bridge.

After the climbing which has been undergone, the prospects for the immediate future are looked upon with equanimity.

WHY STUDEBAKER IS EXCEEDINGLY ACTIVE

DETROIT, MICH., Aug. 2—Is the automobile industry about to witness the formation of another "combine" that will combat the General Motors Company, at present holding the center of the stage through its acquisition of a string of factories in Detroit and throughout Michigan? Those actively identified with the latest move which is causing speculation, deny that there is any thought of a "trust." but wise ones shake their heads and opine that if nothing more tangible comes of it, a hot pace will be set for others as a direct result of the activities of the Studebaker E-M-F interests.

Following close in the wake of the E-M-F Company's purchase of the De Luxe Motor Car Company's plant, and the announcement of the Studebaker-Flanders "Twenty" for next season, comes the news that the same concern has bought outright the plants of the Western Malleable Steel and Forge Company adjoining the De Luxe property, and the Monroe Body Company, of Pontiac, Mich., consideration for both being in the neighborhood of $500,000.

Where the Studebaker-Flanders "Twenty" Will Be Built at Detroit

The acquisition of these plants puts the E-M-F Company in a position where it is practically independent in the matter of drop forgings (in the manufacture of which, on an immense scale, the Western Malleable Steel and Forge Company has been engaged) and in bodies.

Not content with what has already been accomplished, permits have been issued to the E-M-F Company for two new structures it will erect, on land adjoining the De Luxe plant, and which will cost $75,000. Both are to be three stories in height, one 460 x 56 feet on the ground, and the other 240 x 60 feet. It is this rapid expansion on the part of the E-M-F Company and its alliance wtih the Studebaker Company (which will market the entire output of the two local factories in addition to the Studebaker-Garford car) that has set tongues wagging anent the possibility of a "combine" to oppose the General Motors Company.

"Nothing to it," says Walter E. Flanders, president and general manager of the E-M-F Company. "We will be too busy the coming season producing 15,000 Thirties and 25,000 of the new Twenties, to bother about what the other fellow is doing. In order to manufacture cars on such a hitherto unheard-of scale, and turn them out on time, we must have sources of supply that will absolutely insure against anything going wrong. That has been the reason prompting us to acquire these additional properties—that and nothing more. We wanted to be independent. Within a few months, with the additions now being made to the E-M-F plant and the new structures that will shortly be commenced on the property just acquired, we will be in that position."

Fairview's Relations to Chalmers-Detroit

DETROIT, MICH., Aug. 2—The Fairview Motor Company, recently incorporated, is virtually a part of the Chalmers-Detroit Company, organized for the purpose of manufacturing and putting on the market a motor truck (with which experiments have been conducted for some time with success), taxicabs, and other vehicles of a business class. Plans are being prepared for a new $150,000 plant, to be erected near the Chalmers-Detroit buildings.

Rumors to the effect that the E. R. Thomas Motor Company of Buffalo was about to be merged with the Chalmers-Detroit Company gained wide circulation and were given some credence. Hugh Chalmers brands such talk as idle, declaring that a move of this nature is not contemplated. E. R. Thomas also is emphatic in declaring that no negotiations are pending, and that none have been started.

Timken Learns Detroit Is Growing

DETROIT, MICH., Aug. 2—The Timken-Detroit Axle Company has received a forceful but by no means welcome demonstration of the fact that, thanks in a large measure to the automobile industry, Detroit is growing by leaps and bounds. Upward of 300 employes were brought here from the parent plant at Canton, Ohio, when the local factory opened a month ago. Many of the imported men were unable to find houses for their families and returned to Canton. The shortage of houses still continues, and the firm is at a loss to know how the men and their families are to be housed that a sufficient supply of skilled labor may be kept on hand until new houses are erected.

SATISFACTORY END OF POPE RECEIVERSHIP

NEWARK, N. J., Aug. 2—More details of the wind-up of the Pope Manufacturing Company's receivership have been made public since the first announcement last week. According to the final report filed by Sherrerd Depue, representing Albert L. Pope, Egbert J. Tamblyn and George A. Yule, the receivers, 23,714 and a fraction shares of first preferred stock are involved in the reorganization scheme, and there are sufficient assets remaining to pay a dividend of 41.28 per cent. The receivers asked permission to pay into court $8,061.42, representing the dividend on the 195 shares of stock not included in the reorganization, for ultimate distribution among their holders. The report also indicated that the receivers paid to general creditors claims amounting to $1,505,798.30, with interest.

Vice-Chancellor Howell directed the receivers to turn back the plants of the company at Hartford, Conn., and Westfield, Mass., to the reorganization committee, composed of Harry Bronner, F. H. Ecker and Harry Hecksher. This committee further offered to pay all the expenses of the receivership. Mr. Depue also acted for the receivers of the Pope Motor Car Company, and in his report declared that all commissions of the receivers in the various jurisdictions, remuneration for receivers' counsel and all other charges pertinent to the receivership had been settled.

Told in the Progress of the Industry

Longest Trip on a Moon Car—Very recently a long tour, started on the spur of the moment, was taken by a Western man without any necessary repair or replacement to spoil the continuous pleasure of the trip. Starting from Chicago immediately after the Cobe and Indiana Trophy races, A. M. Robbins, manager of the Centaur Motor Co., of Illinois, drove to Jackson, Mich. The next day he drove to Detroit and, putting the car on a boat, he shipped it to Buffalo, running to Geneva, N. Y., that afternoon in a heavy rainstorm. Syracuse was made the next noon and Albany was reached that night, 168 miles in 6 hours and 15 minutes. The next day Robbins made 198 miles to Boston in 10 hours. After driving 700 miles around Boston he came back over the "scenic" route through the beautiful Berkshires and northern Massachusetts—Old Concord, Fitchburg, Brattleboro, Vt., Bennington and Troy. From Albany he drove through Canandaigua, Seneca Falls, Buffalo, Toledo and South Bend. Not once on the trip of 3,000 miles did he touch a tool to the car, not even to replace a spark plug. The day of his return the car went into demonstrating service without being even looked over.

For Premier Owners in Philadelphia—For the entertainment of its numerous patrons, the Motor Company, of Philadelphia, which handles the Premier car in the Quaker City, has promoted a roadability run to Cape May for September 11-12 next. Only owners of Premier cars will be eligible, and the first prize will be a solid silver punch bowl, which will go to the owner of the car who covers the route of upward of 90 miles, nearest to the secret official time. On arrival at Hotel Cape May, all the participants, drivers and friends will become the guests of the motor company, one whole floor of the hotel having been reserved for them. After 6 o'clock dinner there will be dancing in the ballroom, presentation of prizes by President H. O. Smith, and a late supper in the grill room. Sunday morning will be spent in the surf. sailing and fishing and, following midday dinner, the start for home will be made at about 2 o'clock. The company has made arrangements for stops for refreshments at Egg Harbor and Tuckahoe on the downward trip. Thirty-seven entries have already been received.

Injunction Granted to Mezger—In the past the automobile business has been famous for the ease and freedom with which ideas were borrowed bodily, patented ideas being no more sacred than others. Now the situation is beginning to improve, because owners of patents are beginning to fight to retain their rights under the government papers granted them. Thus, the C. A. Mezger Department of the United Manufacturers announces that it has secured an injunction against the New York Sporting Goods Company in the Circuit Court for the Southern District of New York, restraining the latter from selling imitations of the "Automatic" wind shield, or in any way infringing upon the patents controlling the same. Moreover, the Mezger Department announces that the future policy will be to protect itself under all of its patents.

Rambler Winning Honors on Coast—Four hundred and eighty-seven miles, the distance between Los Angeles and San Francisco, in 16 hours 46 minutes and 30 seconds is the new record established last week by L. B. Harvey, of San Francisco, in his new Rambler Close Coupled Model Forty-Five. Harvey left Los Angeles at 3 in the morning, reaching Santa Barbara in 4 hours and 55 minutes. Between Los Olivas and Santa Maria time was lost because of washouts on the road. A puncture delayed the trip at San Luis Obispo, and at one point the driver lost the road, thereby losing half an hour. This Rambler also holds the record for the round trip between Los Angeles and San Diego, winning the Chanslor-Lyon trophy in that run in December of last year. Three hundred and thirty-one miles in 10 hours and 32 minutes, over roads not prepared or patrolled, is the record in this contest.

Automobile Parts Business Expanding—Among the newcomers in Detroit, indirectly connected with the automobile business, is the firm of Schweppe & Wilt, of which W. H. Schweppe is president; A. D. Wilt, Jr., vice president and general manager; Marvine Gorham, secretary and treasurer, and F. R. Heym, factory manager. Starting about two years ago to manufacture steering gears, the growth has been so rapid that incorporation was deemed necessary. Recently the firm has moved into larger quarters on the corner of Meldrum and Champlain streets. In the new building many additions have been made to the equipment, including a large number of automatic and screw machines. With improved factory facilities and a highly specialized personnel, the business is growing by leaps and bounds.

Big Implement House Buys Ramblers—Within the past two or three years, implement dealers all over the country have taken to watching with careful eye the progress of the automobile. In this connection, it is significant to note that one of the largest, located in the middle West, has just completed arrangements to handle the Rambler. This is the Kingman St. Louis Implement Co., St. Louis, and the territory assigned to it is Arkansas, eastern Missouri and southern Illinois. Before selecting this car the implement company satisfied itself as to the selling merits of the same in competition with several well-known makes. The choice of the Rambler is then very gratifying to its makers, the Thomas B. Jeffrey Co., Kenosha, Wis.

Rider-Lewis will Build 3,000 Cars—Attention is called to the fact that when it was stated that the Rider-Lewis Motor Car Company would produce "a small but nearly perfect" number of machines, the word small was used in a relative sense. It develops, however, that this number has been increased to no less than 3,000 cars for the balance of 1909 and the year 1910. In the description of the output of this company in the July 22 issue of THE AUTOMOBILE, it was erroneously stated that the four-cylinder car was equipped with 2 1-2-inch tires. This was a typographical error for 3 1-2-inch tires, the actual size fitted.

Couldn't Have Won Without "Gobbo"—Of the eight starters in the last Brighton Beach 24-hour race, six were equipped with the god of luck, "Gobbo," showing that even the nerviest and most daring of drivers are superstitious. This was distinctly a "Gobbo" victory, as was also the 100-mile race at the same race meeting, in which the S. P. O. car went through the entire contest without tire or other trouble, due to the presence on the radiator of the good luck bringer. Its makers, the Motor Car Equipment Company, New York City, report a very large and growing demand for this and similar emblems.

E. & J. Build in Detroit—The Edmunds & Jones Manufacturing Company, makers of E. & J lamps, are building a new plant which will quadruple their present capacity. It is located at Lawton street and the Michigan Central Railroad. The building is to be three stories high and will be in two wings, 215 feet long and 6c and 90 feet wide. This will give the company a floor space of over 60,000 square feet. In addition there will be a power plant 40x60 feet. Connection will be made with the railroad by a private spur track The factory will be in operation in time to assure prompt deliveries in 1910.

Michelins "As Usual" at Brighton—After the recent Brighton Beach race were over, Wilbur Hobbs, manager o the New York branch of the Micheli Tire Company, although he had been o duty steadily, was not too tired to tal about its victories. "Michelins, 'as usual won first, second and third in the 24 hour contest," he said, "as well as in th 100-mile, and in addition we took fir in the 50-mile, the 5-mile and the mi events. In fact, we secured first pla in every event on both days except in a uncontested 5-mile race and the moto cycle races. That's going some."

Automobile Parade for King Wamb—One of the spectacular features of t King Wamba festival, which is to be he at Toledo, O., late in August, and whi has been extensively advertised througho the country, will be an automobile para It will take place at night, and handso and valuable prizes will be given for t winners in three classes, into which t kinds of decoration are to be divided, vi handsome, grotesque and mechanical. each class the winner is to receive a f silver loving cup with corresponding pri for secondary winners.

Glove Makers Have High Old Tim—On Saturday of the coming week th will be "nothing doing" at the plant the Fried-Ostermann Company, at Ro ford, Ill., since this is the day set as for the employees' outing. Taking steamer to Brown's Creek, the day be spent in having a high old time. elaborate program has been arran including athletic games, baseball gan together with much vocal entertainm An orchestra will be taken along, w the men and women have both for quartets.

Tire Prices Not Increased Proportionately—While the price of all makes of tires has been increased very recently, the manufacturers of Continental tires give it as their opinion that the prices have not gone up as much in proportion as has the price of raw rubber which tire makers are obliged to pay. Attention is also called to the new Continental list, No. 12, and a booklet that has been recently published entitled "Continental Ready-Flated Tires," which is now available for free distribution.

1906 Loco "on the Job"—George T. Lincoln, a Boston automobile enthusiast writes that his 1906 Locomobile has just finished a tour of 1,100 miles in England and Wales. He says the car is evidently determined that no Englishman shall suspect that it has already some 50,000 miles to its credit in the United States. It is running as well as a new car and much quieter than the English cars met on the road. Mr. Lincoln is now in France, where he expects to make a long tour.

Timken Axle Makers' Banquet—The Officers of the Timken-Detroit Axle Company tendered a banquet to their president, William R. Timken, at the Hotel Pontchartrain, Detroit, last week. Among those present were Mr. and Mrs. A. R. Demory, Mr. and Mrs. E. W. Lewis, Mr. and Mrs. H. W. Alden, Mr. and Mrs. F. C. Gilbert and Mr. and Mrs. W. H. Hutton, all of Detroit, and Webb Artz, of Cleveland.

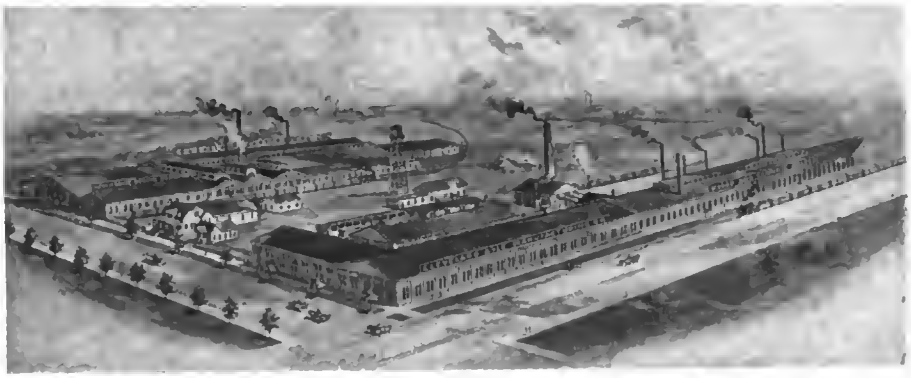
Ajax Shows Well in Glidden—Reports from Denver show that the pairs of Maxwells and of Brush runabouts in the Glidden tour have had remarkably little trouble with their Ajax tires. The Maxwells traveled from the factory, at Tarrytown, N. Y., to Denver, a distance of 2,700 miles, on the original air, and the Brushes would have made a similar record were it not for a single puncture on a rear tire.

PERSONAL TRADE MENTION

D. B. Marwick, formerly superintendent of the Columbia Steel Company, and more recently special steel export with the A. O. Smith Company, has been appointed general manager of the Stanley Steel Works, New Britain, Conn.

R. H. Williams has joined the ranks of the F. B. Stearns Company, of Cleveland and will represent it upon the road in the southern section of the country. He was formerly identified with the retail trade.

William S. Eaton, who, until lately, was with Burr & Co., New York City, has accepted the position of superintendent with James Cunningham, Son & Co.



Cleveland-Canton Spring Company's Factory As It Appears with the Latest Addition

CLEVELAND-CANTON SPRINGS

CANTON, O., Aug. 2.—The Cleveland-Canton Spring Company is now occupying a large addition to its factory, which was recently added to keep pace with its growing trade in automobile springs. It was not until about a year ago that this company seriously engaged in the manufacture of springs for automobile use, but it has met with remarkable success, and is now supplying a number of prominent manufacturers.

The company has spent considerable time and money in experimenting, and has decided that, aside from the proper quality of steel, the most important factor in the production of a spring to meet the exactions of automobile usage is the heat treatment. To carry out its ideas in this respect the company has installed special gas-heated kilns which can be kept at a constant known temperature, and in which the steel bars never come in direct contact with the flame. Supplementing these kilns are a series of oil baths kept at certain degrees of heat to assist in tempering.

The springs in different stages of development are put through many different tests. First is a chemical analysis of the steel bars, showing whether they come up to the specifications. Next are the tests for crystallization and permanent set. Finally the springs are tested for mechanical construction and for carrying capacity, and then, after the final grinding and polishing, they are ready for use.

The exclusive devotion of such a large plant to the manufacture of a single part is one of the best instances of the specialization now characteristic of the automobile industry. That it is a change for the better no one can doubt, as few car manufacturers could afford such scientific methods.

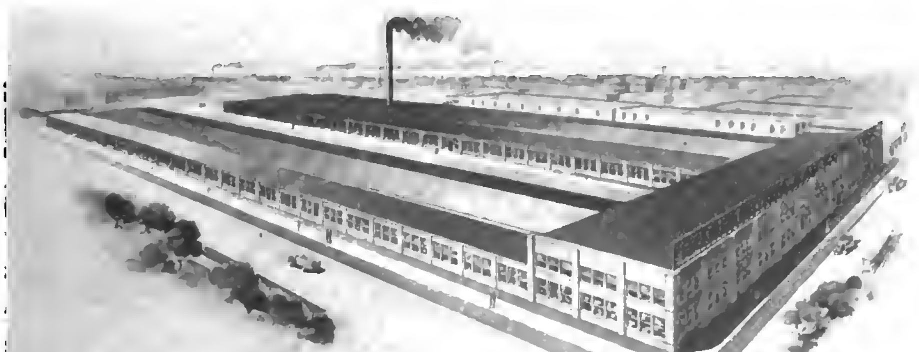
CHICAGO DEALERS' FIELD DAY

The second annual field day of the Chicago "automobile row" was held last Thursday at the Fox River Country Club. More than a hundred dealers, with their employees and friends, made the fifty-mile trip in automobiles and enjoyed a day out of doors. The program included all sorts of athletic and other events, and although no world's records were broken everyone seemed well satisfied. Henry Paulman, the Pierce-Arrow representative, won the golf championship; the bicycle race was taken by Harry W. Cooper, manager of the Excelsior Supply Company's branch; the 100-yard dash went to Harry Watts, of the United Manufacturers; the trap shooting to Thomas J. Hay, manager of the Ford branch; the pool championship to F. E. Sparks, of the United Manufacturers; the swimming race to George Gaidzik, of *Motor Age*, and the bowling to C. G. Sinsabaugh, also of *Motor Age*. Harry Watts took the Paulman trophy for the all-round championship by his victory in the sprint and second place in the swimming race. The roll of the dealers includes some real athletes, too, for George Gaidzik is the Olympic swimming champion.

IN AND ABOUT THE AGENCIES

Thomas, Boston—At the dealers' convention of the E. R. Thomas Motor Company, at Buffalo, last week, it was announced that Charles S. Henshaw has been engaged to open and manage a Boston branch for the sale of the Thomas line. The new arrangement took effect on August 1, and it is the company's intention to establish one of the finest branch houses in the East. Until the new location is decided upon, the Boston headquarters will be at 288 Columbus avenue, where Mr. Henshaw sold Thomas cars successfully for a number of years.

Pullman Agencies—The York Motor Car Company, of York, Pa., announces the following 1910 agencies for the Pullman: L. M. Alleman, Littlestown, Pa.; Longstreth Motor Car Company, Philadelphia; B. F. Futer, Lancaster, Pa.; Hamilton Auto Company, Allentown, Pa.; D. B. Hoffer & Sons, Reading, Pa.; V. A. Simrell, Scranton, Pa.; Syracuse Motor Car Company, Syracuse, N. Y.; Pullman Motor Car Company, Cleveland, O.



Extensive Plant at Detroit, Where the Hupmobile Cars Are Built

Recent necessary additions to the factory where the Hupp Motor Car Company holds forth have brought the size of the plant up to the present imposing appearance as shown in the illustration above.

RECENT BUSINESS CHANGES

King Leather Tire Company, of Milwaukee, Wis., on and after August 1, will occupy new quarters at 3417-3419 Vliet street. The large volume of business done forced the company to make this change.

Information for Auto Users

New Eames Socket Wrench—A socket set which looks as though it might earn its keep in automobile work, is that brought out by the Eames Manufacturing Company, 44 Broad street, Boston. The handle is hinged just above the socket holder, and may be used at any angle; it also has a removable T-head. Twenty-two sockets are furnished, including a special long one

FULL CASE OF EAMES SOCKET WRENCHES

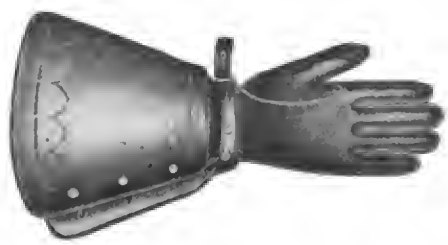
for spark plugs; they are of pressed steel, thoroughly annealed, and are held in place by a friction grip. All common sizes of hex and square nuts and cap screws are provided for. The case consists simply of a heavy wood block bound with brass, with a sheet of oak-tanned leather as cover. There are no hinges or catches to break and no thin wood cover to smash. The leather also keeps the wrenches from rattling. The entire set weighs only five pounds.

Veeder New Small Odometer—The Veeder Manufacturing Company, of Hartford, Conn., recognizing the fact that the small attachments on motorcycles are subjected to very hard usage, has brought out a special type of small odometer or cyclometer for this work. The case is larger in size than in the regular bicycle cyclometer, the gearing is heavier and it is equipped with a larger star wheel. A feature deserving special mention is the adjustable bracket, which can be adapted to any American or foreign motorcycle by adjusting a single nut. The instrument has both trip and season dials, with the mile figures in white and the tenths in red, on a black background. The figures are large enough to be easily read from the seat of the machine. The cut, about two-thirds full size, gives a very good idea of the neat and compact appearance of the instrument in its entirety.

SMALL VEEDER ODOMETER

General Accumulator Company Specialties—A good line of automobile specialties has been put on the market by the General Accumulator and Battery Company of Milwaukee, Wis. One of these is the "Radium" battery, of which the distinctive feature is the gauge, which tells the available charge at any time, and obviates the possibility of running out of current on the road, as well as the danger from overcharge. This company's decarbonizer has been on the market for four years, and has found a wide recognition among autoists who tried its use in cleaning their cylinders. The advantages of the chemical method of removing carbon over the mechanical method are now widely admitted. A third specialty is a new spark-plug, which is doubly insulated. All the lower inside walls are lined with durable fireproof porcelain, in addition to the usual porcelain insulation, so that short-circuiting is practically impossible.

New Price Automobile Gauntlet—A new style of the Price gauntlet has been put on the market by the makers, the Fried-Ostermann Company of Rockford, Ill. Many autoists will find this gauntlet very convenient, as its construction permits either a broad, flaring cuff, as in the familiar non-adjustable types, or one

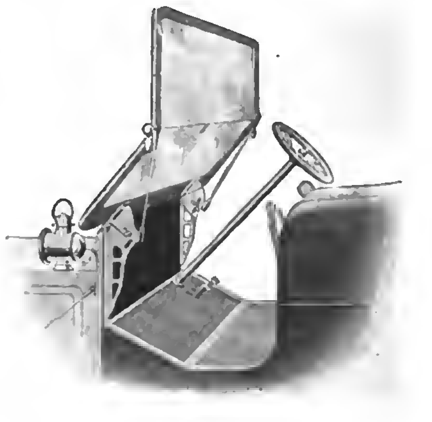


NEW STYLE PRICE GAUNTLET GLOVE

that will fit the sleeve of a light-weight coat snugly, keeping out the dust. The adjustment is accomplished by means of snap buttons and requires only a few seconds' time.

Perry Non-Skid Tire Chains—This new device, marketed by the Perry Chain Grip Company, of Lansing, Mich., differs in several respects from the usual type. All the cross chains are swiveled, so that they wear on all sides equally. Then, too, each cross chain has a spring tension hook, which keeps it tight and prevents rattling. Should one break, there is no need to go on with the ends rattling against the fenders, as a new one can be snapped in place in a few seconds. The separate cross chains are sold at a nominal price and a few of them can be kept in the tool box.

The Burrowes Wind Shield—The Burrowes wind shield, made by the E. T. Burrowes Company of Portland, Me., is of the divided type, but differs from the usual construction in that the angle of both the upper and lower portions is adjustable. It may thus be placed in half a dozen different positions to suit the driver's convenience. It may be set with both sections vertical, in line with the dash, in the usual position; or the upper section may be folded down on



DIVIDED TYPE OF BURROWES SHIELD

the lower, and both tilted back, so that their upper edge is well below the driver's line of vision. For work with a cape top in stormy weather it may be set with the lower section tilted back and the upper vertical; in this position its upper edge is far enough below the top to allow a ventilating current of air to pass, while at the same time it is far enough behind the front edge of the top to keep out the rain. Another desirable feature is that there is no horizontal brass bar on the dividing line to obstruct the driver's view. The frame of the shield is made in wood, either birch or mahogany, reinforced with metal. A rain-drip extends over the joint with the dash, thus preventing water from running down on the inside. The plate glass of the top section is 3-16 inch thick and that of the lower section 1/4 inch; the upper overlaps the lower 1/2 inch, thus making a rain-proof joint. When adjusted and locked in any position the shield will not rattle, and, in fact, is said to be more rigid than most non-adjustable screens.

Stamped Aluminum Floor Covering—The Factory Sales Company, 1438 Michigan avenue, Chicago, announces a new automobile floor covering, for which is claimed many points of superiority over rubber, corkaline and other materials. This flooring is stamped from an aluminum alloy into pyramid shape, and is afterward sand-blasted to give a uniform rough finish. It is designed to lay over the regular floor boards, secured in place by special binding strips. The metal is much harder than ordinary aluminum, making it very durable. Its most attractive feature, of course, is its cleanliness. It is furnished in sheets 36 x 85 inches, and as it is finished clear to the edges there is no waste. This flooring is being adopted by several makers, and will be found especially helpful to those who are rebuilding or remodeling old cars.

To Keep the Machinery Clean—The Auto Waste Company, of Hartford, Conn., has placed on the market a high-grade Sea Island long-fiber waste, especially made for automobile use. The same company also makes a line of wiping cloths of all sizes.

VOL. XXI NEW YORK—THURSDAY, AUGUST 12, 1909—CHICAGO No. 7

THE AUTOMOBILE

VICE-PRESIDENT HONORS RICHFIELD CLIMB

Vice-President Sherman Presenting Trophies to "Billy" Bourque

Bourque, Knox Three-Time Winner In Action

RICHFIELD SPRINGS, N. Y., Aug. 7—Never before, in these United States, has one high in the councils of the nation favored an automobile event with his presence. Today's hill-climb had as its chief attraction, James S. Sherman, Vice-President of the United States, whose home is in Utica, not many miles from this delightful pioneer resort among the Otsego hills. Vice-President Sherman toured here from home in his own car, enjoyed a fast canter over the course in an ex-Vanderbilt race participant, and then graciously presented the prizes to the winners, punctuated more or less with the famous smile which has won for him the sobriquet of "Sunny Jim."

"Billy" Bourque, driving a pair of 1910 Knoxes, was the substantial winner of the meet, for his victories were gained with stock cars similar to those anyone may purchase from the factory in Springfield, Mass. Of course, the spectacular feature of the climb was contributed by Fred. K. Burnham at the wheel of the 120-horsepower Fiat racer which Lancia piloted in the Vanderbilt Cup race of 1906. But when one realizes that the car from Italy is rated at 120-horsepower, while the American stock contestant only boasted of 40-horsepower, the real honors belong to the latter, even in the free-for-all; for Bourque first tied Burnham in :47 2-5, though in the run-off the American fell back :48, while the foreigner cut its time to :45 4-5, which was a mile-a-minute for the nearly three-quarters of a mile course.

It so happened, in order to get the starting place in front of the Hotel Earlington (whose proprietor, Gasherie DeWitt, was responsible for the holding of the climb) that the distance was just twenty-seven feet more than the three-quarters, allowing for a flying start and plenty of room in which to slow down after passing the finishing mark. A most convenient road in the rear

Burnham, Driving ex-Vanderbilt Cup Fiat, Winner of Free-for-All

provided a return to the starting point without utilizing the course, thus preventing delay in running off the events. While the surface of the road was rather rough, it had been carefully prepared for the day, with dust practically eliminated. The arching shade trees added much to the natural beauty of the picturesque course.

Although there were some scratches in the entry list, the fifteen cars participating appeared several times, which, together with the practice spins, gave the spectators a sufficiency of sport. Next to the ex-Vanderbilt racer and the star Knox performer, the fastest car was a 90-horsepower Simplex, in which amateur Burnham again figured as the steersman. Its winning of the $4,000 and over class was accomplished in :52. The two Knox cars have new engines in which the bore has been increased an eighth of an inch for the 1910 season, one being equipped as a runabout and the other contesting in stripped form. Two of the new four-cylinder model Q Maxwells appropriated honors in the small-car class, with Arthur See at the wheel of the faster one, which made its climb in 1:13 4-5. The Pierce Arrow, with "Tony" Ledermann driving, had an unopposed victory in the six-cylinder class, and the Buick also took two events with nothing to compete against except the electric timer.

The clocking was attended to by P. A. Sayles and George McGraham, of the Timers Club, of New York. They had the device on hand which has been used at all of the prominent automobile race meets, and it gave the usual complete satisfaction. McGraham took care of the start, being on the line with Vice-President Sherman, and as each speeding contestant passed he pressed the key, which did the work at the business end of the instrument—at the top of the hill. Three stop watches were started, when the circuit was closed at the foot of the climb, and Sayles presided over them at the finish.

With Fred Wagner's characteristic celerity as starter all the events were run in slightly over an hour, with no waits except when the Chalmers-Detroit was stripped for the free-for-all, and when another car had to go down the back way to take part in the next class. The contestants were always lined up in readiness for the signal, securing a run of about 100 yards from the center of the town before crossing the tape. There is a slight dip just over the starting line and then the grade commences, so that the machines attained a considerable speed before beginning the ascent. The course itself is nearly straight, there being one slight curve to the left half way up, but this was not enough to cause skidding or any sensationalism. The roughness of the surface, however, caused some pronounced swerving when speeding towards the finish, and Bourque's stripped Knox did some jumping as it flew alongside a white fence at the roadside.

Competition opened with an event for the smallest cars admitted, those selling from $851 to $1,250, and this was taken handily one, two, by the new Maxwell runabouts of 22.5 horsepower. The Hudson was a close third, however, for its time was but four-fifths of a second more than the 1:13 4-5 of the winner.

A Chalmers-Detroit 40 was a splendid runner-up to Bourque's Knox in two classes, the cars being evenly matched in regard to engine size, and the Chalmers might have done better than its :54 3-5 in the free-for-all if its seat had not slipped off.

Burnham, with a Simplex, won the event for the four-cylinder general selling for $4,000 or over, his time being :52. Unfortunately, his machine was placed out of running order soon after passing the finish line by hitting a concrete culvert at the turn to the back road. Here he left it and jumped another car to get to the starting line for the free-for-all, in which he drove his big Fiat. Tony Ledermann, unopposed, took the

"Tony" Ledermann and the Pierce Six Which Had a Walk-Away class for sixes with a 48-horsepower Pierce Arrow.

Just after the finish of the contest the crowd at the hotel was given a real scare and only quick action averted an accident. Vice-President Sherman had been given his ride over the course, holding the prize won by Burnham in the free-for-all, and had been safely deposited at the starting line. Then Burnham started to turn to go to the garage, but his steering gear jammed and the big car, going at a 20-mile-an-hour clip, leaped for the sidewalk and the crowd. Brakes held, however, and the people scattered very quickly, so that when the machine stopped on the sidewalk no damage was done. It was considered particularly fortunate that the derangement occurred after Mr. Sherman had disembarked.

Burnham at Wheel of the 90-H.P. Simplex, Winner of Its Class

The day was truly a gala one for this part of the country, and hundreds of automobile touring parties arrived during the morning, parking their cars along the route of the climb or leaving them at the bottom and walking up. It was estimated that about three or four thousand people were on the roadside, and the course was kept clear by local police and firemen in uniform. Automobile clubs in neighboring cities had planned organized runs, but this idea gave way to the separate party method, and from Syracuse, Binghamton, Oneonta, Utica, Rome, Herkimer and even Buffalo and Albany the tourists came. The result was that all roads led to Richfield Springs yesterday and to-day.

The officials of the hill climb were as follows: Referee, Samuel B. Stevens; honorary referee, F. H. Elliott; clerk of course, Thomas J. Wetzel; starter, Fred J. Wagner; judges, H. W. Smith, president Automobile Club of Syracuse; George A. Frisbie, president Automobile Club of Utica, and George W. Baird, president Automobile Club of Oneonta; timers, P. A. Sayles, George McGraham; technical committee, C. H. Norris and C. A. Benjamin, of Syracuse, and Frank Miller of Utica; observers, G. H. Norris, H. L. Conde, M. W. Kerr.

The contest committee was composed of H. N. DeWitt, chairman; Fred Bronner, F. E. Munger, C. B. Conrad, I. J. Kent, Thomas J. Wetzel, W. H. Keller. The local committee included J. D. Cary, chairman; Gasherie DeWitt, W. T. Johnson, Otto Singewald, W. T. Welden, Richard Purcell, Frank Roff, G. W. Hyde, S. H. Conklin, A. J. Bloomfield, George Tunnicliffe.

Handsome silver loving cups were presented to the winners of the various classes, and in the free-for-all there was a second prize also. The DeWitt trophy for the open event was presented by Proprietor DeWitt, who was responsible for the day of sport, for which came automobilists from a large section of the Empire State.

Herewith are the summaries of Richfield's first hill climb:

Pos.	Car	H.P.	Bore	Stroke	Driver	Time

Automobile Club of Richfield Springs Organized

There were a large number of automobilists around Richfield Springs who have long wanted an organization to aid the good roads movement, to hold climbing contests and to facilitate the spread of touring information. This evening Mr. DeWitt of the Earlington; his son, H. N. DeWitt, who is chairman of the contest committee, which was formed temporarily for this meet; William T. Johnson, proprietor of the Hotel Berkeley-Waiontha; Fred Bronner, the postmaster, and a number of others formed the Automobile Club of Richfield Springs. There are about fourteen charter members, and many more have promised to join. The following officers were elected: President, William T. Johnson; vice-president, Thomas J. Wetzel; secretary, Fred Bronner; treasurer, John D. Cary. A committee on by-laws and constitution was appointed as follows: G. DeWitt, A. J. Bloomfield, G. E. Tunnicliff.

Four honorary members were elected—Hon. James S. Sherman and three Freds—Fred J. Wagner, Fred H. Elliott and Fred K. Burnham. Mr. Elliott represented the A. A. A. at the meeting, and assisted in the formation of the definite rules and plans of the organization.

The local club, supported by the hotels and townspeople, will endeavor to secure the first convention of the New York State Automobile Association, which will be held next July, with a large hill-climb at the same time.

Secret Time Run Round Canadarago Lake

Friday afternoon there was a "sociability run," the route being twice around Canadarago Lake, and the time was a secret held by William T. Johnson, who marked off the distance and set the schedule. Thirteen cars started, but one, Mr. Kent's, was unlucky and had a puncture and withdrew. The time which Mr. Johnson had decided upon was two hours, and the nearest to it was Adolphus Fiegenheimer, in an E-M-F, who consumed 1:29:31¼. The farthest from the guess was C. B. Conrad, who drove his Pope-Hartford around in 1:13:06 3-4, winning the consolation prize. C. W. Root drove his Haynes over in 55 minutes 8 seconds, but this was greater than the legal speed limit, and so the consolation did not go to him.

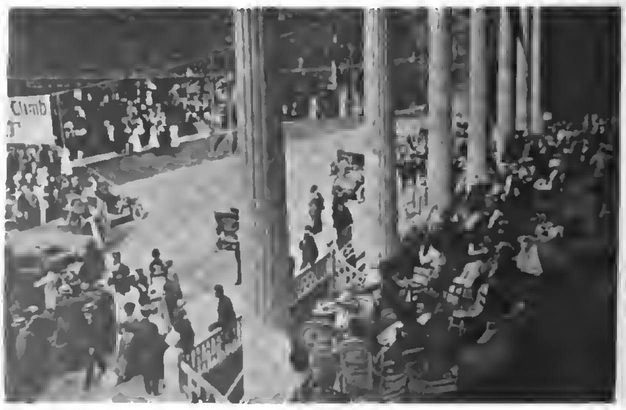
The following is the result of the run, with the time of each contestant:

Entrant	Car	Time
A. Fiegenheimer	E-M-F	1:29:31 1-4
Dr. C. C. Ransom........	Elmore	1:24:22 1-2
Percival Jones...........	Knox	1:21:15 3-4
H. L. Conde.............	Thomas	1:21:14 1-2
A. M. Zabriskie..........	Knox	1:20:21 1-2
Joseph Kaeslin	Ford	1:18:35
H. F. Mansfield..........	Stevens-Duryea	1:18:27 1-2
H. H. Cooper............	Stevens-Duryea	1:18:04 1-4
T. J. Wetzel.............	Selden	1:17:58 1-2
Oliver Drake-Smith	Cadillac	1:13:39 1-2
C. B. Conrad.............	Pope-Hartford	1:13:06 3-4
C. W. Root...............	Haynes	:55:08

The officials were: Judges, J. W. Ward, Benjamin Brown, C. H. Lang; starter, William T. Johnson; clerks, Richard Cary, L. G. Foster; timers, C. E. Caney, F. E. Mungor.

From the popularity of this little run, and the puzzle accompanying it, it is likely that a repetition will occur at an early date. A number of autoists who are spending the Summer in this locality have promised their support with entries.

Line-Up in Front of the Roomy Earlington



From the Hotel's Capacious Colonial Veranda

M. C. A. WILL HAVE RULES CONFERENCE AT INDIANAPOLIS

HOWARD E. COFFIN, chairman of the general rules committee of the Manufacturers' Contest Association, outlines most interestingly the matters which will call for consideration at the session of the committee to take place at Indianapolis, August 19, 20, 21, at which time the new Indianapolis Motor Speedway will have its dedicatory race meet. Unquestionably, the manufacturers who support racing should concern themselves in the framing of the rules, and while the regulations for 1909 have not met all the requirements, at the same time a big step was made in the right direction.

The M. C. A. leaves to the contest board of the American Automobile Association the final adoption and enforcement of the rules recommended by the M. C. A. Chairman Coffin, in outlining the work to be taken up at the Indianapolis meeting, has the following to say:

CONCERNING INTERNATIONAL COMPETITION—To a lack of proper preparation, rather than to an inferior mechanical excellence, can be ascribed nearly all the humiliating performances of American-built cars when entered in international contests. All of us, importers and American manufacturers as well, are prone to excuse a poor performance upon the part of our cars, whether the event be local, national or international, on the ground that we did not have sufficient time at some stage of the game to get either our organization or our cars into proper shape for the competition. This condition of chronic "unpreparedness" can, in the case of the American manufacturer, be partially ascribed to a lack of attention given to such matters on account of the prossure exerted in other lines directly associated with the producing and commercial ends.

Many times in the past, particularly in the case of events of national or of considerable local importance, insufficient notice as to date and conditions upon which and under which a contest is to be run has been given to those who have been asked to support the event with entries. An important bit of work which is now being pushed by the M. C. A. will certainly go far toward putting an end to this kind of trouble, with a result that the average car entered in 1910 competitions should make a much better showing before the public than in the past.

WHAT M. C. A. HAS ACCOMPLISHED.—The Manufacturers' Contest Association, embracing within its membership those American manufacturers and American importers of foreign cars who firmly believe in the value of that class of publicity which may be obtained from competition in properly governed and properly conducted motor car contests of every kind has, since its foundation in Chicago last February, taken many steps toward the elimination of the chaotic conditions pertaining to contest matters.

From the beginning the work of this organization has been aimed toward an elimination of the causes of the trouble rather than toward the application of a cure to each individual complaint. The removal of the causes that have gone to encourage the old excuse of "If we had only had another week's time," is certainly not the least of the several lines of work mapped out by the M. C. A.

The constitution and by-laws of the organization call for a meeting of the general rules committee each year in August. On this general rules committee are the representatives of twenty-five of those concerns—manufacturers and importers—who have shown the most activity in contest matters during the past two years. This meeting is scheduled this year at Indianapolis, Agust 19, 20, 21, at the time of the opening and initial race meet of the Indianapolis Motor Speedway—the first of the several great speedways that are being built or will be built in America on the plan of the famous Brooklands track, near London.

At this meeting will be discussed all recommendations regarding the rules, changes in rules, classification, etc., for 1910. All changes suggested by the actual experiences of the present season will be considered.

It is unfortunate that the incorporation of the M. C. A. occurred so late in the spring of this year that the revised classifications and rules could not be announced at the beginning of the season. Otherwise there would have been avoided much of the uncertainty that has existed in contest matters the early part of this year.

Plans for 1910—In September, immediately following the August meeting of the general rules committee, and as a direct result of the findings of this committee, announcement will be made as to the changes in the present governing rules and classifications, accompanied by the publication by the contest board of the A. A. A. of the annual rules book, wherein will be covered all conditions governing motor car events to be held between the dates of January 1 and December 31, 1910. At the same time will be published a complete schedule giving the approximate date and all necessary information pertaining to each and every contest of importance which is to be run during the season of 1910.

With such an announcement made in September, coupled with the publication of the rules and conditions, which become effective January 1, there can be little reason or excuse for a lack of preparation on the part of any manufacturer or importer who proposes to make entry in contests of any kind.

The M. C. A. does not control contests, local, national, or international. In all national affairs this association recognizes the direct and supreme control of the contest board of the American Automobile Association.

All international matters clear through and are handled by the Automobile Club of America. The exact relations existing between the M. C. A. and the other two organizations mentioned are outlined in formal contracts which have been or soon will be executed in due form.

Printed blanks have already been sent out from the secretary's office of the M. C. A. to those manufacturers and importers enrolled as members, and on these blanks are being sent in the suggestions which will outline the attitude of the majority upon all items of national and international importance. All recommendations on international matters will, after discussion at the August meeting, be formally transmitted to the Automobile Club of America, and will later, through its delegates, be presented at the international conference abroad.

Things to be Discussed.—Among the more important subjects to be discussed in Indianapolis are the following:

1. Recommendations as to changes in the classifications and weights for 1910 season.
2. Changes to be recommended to the contest board for the American Automobile Association rules of 1910.
3. The possibility of the support by the M. C. A. of an impartial and thoroughly capable technical committee, which shall serve at all competitive contests.
4. The arrangement of a definite and logical schedule of all important contests for the season of 1910, with a view to the announcement in September of this year of the approximate dates, character and general conditions governing all such events. (From information at hand it is a certainty that the promoters of all annual events will for 1910 be very glad to cooperate, as may be suggested by the M. C. A., in so scheduling these contests as to avoid interference of dates. The interests of the promoter and of the manufacturer who is asked to support the contest with entries are mutual.)
5. National events. How many shall be supported and of what character?
6. International events. How many shall be supported and of what character?
7. Endurance contests. Action to be taken upon the recommendation made by the National Association of Automobile Manufacturers, that only one endurance contest be scheduled for any one section of the country and not more than four be supported by manufacturers' entries.
8. Road racing versus track events upon specially constructed speedways of any less than two miles in circumference.
9. Shall racing on existing mile and half-mile horse tracks be countenanced or supported in any way?
10. A standard electrical timing device for the elimination of human error in the timing of all important speed events.
11. A satisfactory definition of the term "Stock Car."
12. Steps to insure the enforcement of the rule governing the character of the publicity matter employed by any maker concerning the performance of his cars in any contests. All such publicity must be in accordance with the facts.
13. A formula for the proper comparison of the performances of steam and gasoline automobile motors.

LIGHT CAR INNING WITH NEXT "24"

NEW YORK, Aug. 9—Light weight and medium priced automobiles will have a grind of their own in the race meet scheduled for the Brighton Beach track for August 27-28. The popular interest in long-time contests has proven so great that the Motor Racing Association has decided to allow the smaller class machines to race for six hours on the first day, so that a contest longer than any light car road race will result. The dividing line will be $2,500, and those above that price will be eligible for the 24-hour contest which will start in the evening as usual. The six-hour run will commence at 11 o'clock on Friday morning, and there will then be continuous racing throughout the afternoon. The entry fee for the small machines has been set at $75, and the prizes will amount to $50 in cash or plate, the first prize being $30. The amounts for the big fellows remain as previously—$500 entry fee, and prizes totaling $2,100.

Between the two long races there will be three short ones, a five-mile free-for-all, mile time trials, and a 25-mile event for cars costing from $1,201 to $3,000.

Chadwick Six Climbed Fastest at Algonquin

Zengle's Chadwick Six in Its Free-for-All Flight in Pursuit of the Famous Algonquin Cup

CHICAGO, Aug. 7—Excelling in perhaps the most brilliant hill-climb field of the season, Len Zengle's Chadwick Six captured the Algonquin cup in the fourth annual event of the Chicago Motor Club, held at Algonquin on Thursday. To get a "leg" on the trophy in which Frank Leland and the Stearns have an interest, Zengle had to break records on the two hills ascended, his margin of victory being 2 4-5 seconds.

The Algonquin cup, now a classic, was put up by the residents of Algonquin, and the conditions are that it goes to the car making the fastest total time on the two hills, regardless of class. The first winner was Frank Leland, who had the fight of his life to get it, there being only three-fifths of a second between him and George Salzman in the Thomas Six. The same car figured in the battle of Thursday last, and it was Greiner in this same Thomas that was the runner-up.

Eighty-five entries were made in 22 class events; 71 started and 67 climbed both hills. As usual, the meet was well handled, the only difficulty being to clear the hill of sightseers and vehicles, which delayed the start both morning and afternoon. It had been planned to have militia guard the course, and soldiers would have been available had it not been for the objection of a neighboring village, which evidently did not like to see Algonquin get so much of the limelight. However, local marshals did very well, and the whole card was run off without a mishap.

Only once was there the slightest accident, that occurring when Shetnitz, an amateur driving a Chalmers-Detroit, had his steering gear go wrong while climbing Phillips Hill in the afternoon. The tie-rod between the knuckles pulled out at one of the joints. It was near the top, and for a moment it looked as if disastrous consequences would result. But the amateur pluckily brought his car to a stop just before the tape was reached.

This year's climb differed somewhat from previous ones. The old system of classification by means of piston area was abandoned because it conflicted with the new scheme devised by the Manufacturers' Contest Association and adopted by the American Automobile Association for uniformity's sake. The field was, therefore, classified by piston displacement and also by price. Time decided the winners in all but class A 2, in which the results were reached by means of the club's formula, in which the piston area is multiplied by the time and the result divided by the weight of the car with its load. In addition to the regular A. A. A. card, there were added events for motor buggies and electrics, and the amateurs were also cared for. The owners competed with the tradesmen, but their time figured in deciding the amateur championship.

As in previous years two hills were used. In the morning Perry Hill, about a quarter of a mile in length, was tackled from a standing start. In the afternoon the contestants went up Phillips Hill, half a mile in length, and from a standing start. The time made on both hills was used in deciding the winners. Both hills were in the best of condition.

Father Time suffered most on Perry Hill, where four cars beat the old record of :24 1-5 and two others tied it. On Phillips Hill the Chadwick was the only one to get inside of Leland's :29 2-5, registering :28, whereas Greiner in the Thomas tied the record.

When the program was first announced, everyone looked for a speed battle in the free-for-all, for undoubtedly it was one of the best fields of the year. Denison in the big Knox was the first one to make the spectators sit up and take notice. Denison had made a good climb in the morning, and when he negotiated Phillips in :30 1-5 one hardly looked for him to actually lift the cup. Then Greiner shot his bolt, and tied the old record. With the shade he had over the mark in the morning it looked as if an amateur might reap the honors of the day.

But the Chadwick had yet to come up, it having been given the last number in the bag. So the crowd settled back for the grand finale, and it was not disappointed, for Zengle came up old Phillips with a roar and dash that made it clearly apparent even before he had crossed the tape that the cup belonged to him. And so it proved, for he had done :28, lowering the record 1 2-5 seconds and making his total time :50 3-5 as against :53 2-5 for Greiner.

Class F, division 1, limited to cars with displacement not exceeding 390 cubic inches, was styled the little free-for-all, and proved to be a classy event which attracted the Stoddard-Dayton, Buick, Knox, National, Corbin, Marion and Kisselkar, some of them having in two cars. The Stoddard driven by Bert Miller had the speed of the party, getting first place by one-fifth of a second over the Buick driven by Burman, the total times of the two leaders—:56 2-5 and :56 3-5, respectively—comparing most favorably with that of the cars in the big class.

The Knox drew first blood in division 1 of class B, for cars from 451 to 600 cubic inches of piston displacement. It was the big Knox, and Denison drove. Its time was :53 3-5, with Englebeck the runner-up in the Stoddard-Dayton, and he was only two-fifths of a second faster than his teammate, Miller.

Burman in the Buick was the top-liner in division 2 of this class, which was for the 301-450 class. In this Burman beat Miller in the Stoddard Dayton, who, however, evened up the score in the little free-for-all, where the positions were reversed. Denison in the little Knox was third, but 2 2-5 seconds slow.

The Corbin won in the third division, the 231-300 [illegible], its nearest competitor being the Moon, driven by Phil Wells. Both these cars were in the Indiana trophy road race last July. In this class the Falcar, also a reminiscence of the Crown Point races, made a good run into third place.

In division 4, from 161 to 230 cubic inches, the Velie, Chalmers-Detroit, Mason and Moline battled, and it was the Velie, a newcomer in competition, that won handily, beating the Chalmers driven by Knipper 1:03 4-5 to 1:06 1-5. A surprising climb was made by the two-cylinder Mason, which was only three-fifths of a second slower than the Chalmers. Earlier in the day the Mason had given indications of its speed when it tied the Velie in division 2 of class F for cars not exceeding 202 cubic inches piston displacement. In this each did 1:00, but the Velie improved on this in the event which it won.

In the motor buggy division two Holsmans and a Schacht fought it out, with the Holsmans running one, two. In the electric division the Babcock won with :34 1-5 on Perry and :47 on Phillips, a big cut of the records made two years ago.

There were six divisions in class A, in which the classification was made by price. In conjunction with this were run the formula events of class A 2, one climb sufficing for both. In division 1 Greiner, in the Thomas six, had a walkover. In division two just the two Stoddards ran, Englebeck winning in :59 and Miller being second in 1:00 1-5. The Knox had five seconds the advantage over the Kisselkar in division 3, with the Grout third. In division 4 seven cars started and the Oakland, driven by Howard Bauer of Buffalo, trimmed the Velie.

The two-cylinder Mason was the winner in division 5 of class A, the defeated being the Maxwell and Buick. In this event there was a difference between first and second of 13 1-5 seconds.

The card had been opened by a duel between the little Hupmobile and the Maxwell Junior, in which the latter scored.

How They Finished in the Formula

One of the closely-watched phases of the climb was the performance of the cars in six events, in which the winner was not necessarily the fastest car up the hill, but rather was determined by formula, in which the car weight with driver was divided into the product obtained by multiplying the piston displacement of the motor in cubic inches by the time in seconds required to climb the hill, the lowest result being the winner. The formula is intended to allow for the varied differences in car weight and motor sizes, and is really a motor efficiency test. The tabulation shows how closely the work of each car is covered. In division 4 premier honors would have gone to No. 8 Velie, but its disqualification for not carrying a muffler gave No. 10 Kisselkar the prize, on a percentage of 7.86. This was not so low a percentage as that made by the Apperson last year, which set a mark of 6.42, the best percentage ever obtained by any car in the climb. Second honors this year went to the No. 5 Mason and third honors to No. 10 Kissel. The summary:

No.	Car	Driver	A.M. Time	P.M. Time	A.M. %	P.M. %	Total %
	Division 6—$850 and Under						
1	Maxwell	Smith	42 3-5	64 3-5	3.89	5.89	9.78
2	Hupmobile	Hearne	46 3-5	75	3.86	6.22	10.08

*Amateur.

This year's was the fourth annual Algonquin hill-climb, and was in charge of the Contest Committee of the Chicago Motor Club, consisting of Charles P. Root, chairman; Frank H. Trego, secretary; C. A. Tilt, Bick Edwards, Frank H. Martin, H. P. Branstetter, J. B. Diebler and Oliver G. Temme. The officials were F. C. Donald, referee; David Beecroft, chairman; F. E. Edwards and Berne Nadall, judges and technical committee; Oliver G. Temme, starter; Frank H. Martin, clerk of course, and Walter F. Zimmer, his assistant; Frank H. Trego, chief timer, and Bick Edwards and A. Adams, assistants; Frank E. Sparks, chief observer; Thomas J. Hay, marshal; L. H. Jackman, announcer, and C. G. Sinsabaugh, in charge of the publicity. Many names well known in automobile sporting circles will be recognized in the list. Their efficiency received the best possible endorsement in the smoothness which distinguished the trials.

BLUE GRASS MEET

LEXINGTON, KY., Aug. 9—At the opening of the Blue Grass Fair in this city to-day James B. Ryall, John Aitken, and Louis Strang furnished some of the best automobile racing ever seen upon the fast Fair Grounds track. A number of track records were lowered, among them being the mile held by Barney Oldfield. Aitken, driving a 60-horsepower National, clipped one-fifth of a second from the old mark, setting the record at 58 3-5 seconds. He also won the 50-mile race against Strang, the time being 53:28 3-5. Tom Kinkead, driving another National, won the 10-mile handicap, with one minute allowance, Aitken being second and C. C. Merz in a four-cylinder National third. Ryall drove a Buick, and won the five-mile event in 4:52 1-5.

CANADIANS TOUR

FARGO, N. D., Aug. 9—Preparations are being made to give the members of the Winnipeg Automobile Club a hearty welcome when they arrive here on their tour. It is said that 150 cars are being made ready. Their tour will last three weeks, during which they will cover about 500 miles. They will pass through Moose Jaw, Saskatchewan, then southward to Devil's Lake, N. D., and Fargo, with a side trip to Minneapolis, Minn.

WHAT OF THE BIG ENDURANCE TOUR FOR 1910?

NEW YORK, Aug. 9—While the gathering at Indianapolis next week of the general rules committee of the Manufacturers' Contest Association may result in some discussion of the conditions for the 1910 annual endurance tour of the A. A. A., it is not anticipated that anything definite will be reached at this particular time. Even those who are firm in their belief that an event of this character is a good asset for the industry are divided among themselves as to what should be done another year, and many are not yet sure in their own minds as to definite revisions of the 1909 rules, which left much to be desired in various directions.

There is a growing impression that in the effort to obtain prize-winners, the penalizing business is being carried to an extreme; in other words, this insistent demand for possessors of the trophies has led to the punishment of cars in such manner as to give the general public a very false impression.

One well-known New Yorker representing a car which has been in the tour several times, summed up the situation in this vein:

"Supposing the excessive vibration over roads undeserving of the name should loosen a mudguard, or perhaps shake off a tail lamp. Is that any reason why the running qualities of a car should be subjected to penalization? For it is almost an utter impossibility to make clear to the general public the relations which different forms of penalization bear to the quality of the car itself. The average man simply knows that a car didn't win a trophy and that it was penalized a certain number of points. While every man is not influenced in his buying of a car by results obtained in competition, it is, nevertheless, a fact that many a man is influenced against buying a car because it may have met with penalization in some form or other in a big contest. Until the rules are made more explicit and sensibly applicable than was the case this year, there will not be in 1910 any large field of participants."

It is not likely that a meeting of the contest board of the A. A. A. will take place until early next month, which means that the protests filed by H. O. Smith, of the Premier Motor Car Company, and W. H. Van Der Voort, of the Moline Motor Company, will remain unanswered for the present. It will be remembered that these two protests were leveled against Pierce cars Nos. 9 and 108 for failure to finish with tail lamps.

There is some discussion among automobilists generally, as to the chairmanship of next year's tour, and while Frank B. Hower stated that this year was the last one for him, it is said that his friends will urge him to seek a continuance in office. Whoever tackles the job is certain to know that there is some work connected with it. To satisfy all participants is impossible.

A MAKER'S IDEA OF THE GLIDDEN TOUR

Editor THE AUTOMOBILE:

Now that the Glidden Tour is over and the manufacturers and contestants have had an opportunity to view the event from a commercial as well as a sporting standpoint, they cannot help but arrive at two conclusions.

First, that the tour was a great success in the development of the business in the section of the country through which it passed; and second, that for the coming season the rules should be more strictly and scientifically drawn than they were this year.

For instance, in this year's run, cars which experienced considerable difficulty could still make a perfect score, as there were no penalizations for adjustment of carbureters, ignition troubles, oiling or adjustment of brakes, and cars were allowed to be towed. Had the rules taken these matters into consideration there would have been a very different ranking of the cars at the end of the run. We believe that ignition trouble to the average automobilist is one of the most serious difficulties he experiences, and is the cause of more troubles and stoppage than any other one thing. The oiling system is undoubtedly of the utmost importance to the life of a car, and should be put to the most severe test. Dependable brakes are a necessity, and it does not seem that cars should be allowed to make repeated adjustments to them without penalization.

We wish to call attention to the fact that the Maxwell cars made the entire run without adjustment of carbureter, ignition or oiling system, and were not towed up any hills. Their tire troubles were a minimum—but two punctures—and the same casings were used through the entire trip.

We trust that next year you will use your influence to make the run even more strenuous than it was this year, and to have the rules made up in a way that would give the low-priced cars equal footing with the high-priced ones. We believe that the most suitable route would be from the Atlantic to the Pacific.

MAXWELL BRISCOE MOTOR COMPANY,
Tarrytown, N. Y. C. W. Kelsey.

NORTHWEST TO HAVE "LITTLE GLIDDEN"

MINNEAPOLIS, MINN., Aug. 9—A "Little Glidden" tour under the auspices of the Minnesota State Automobile Association has been arranged for August 27-September 1, the course to be between Minneapolis and St. Paul and Fargo, N. D. The distance is a little over 600 miles. Each car will carry an observer, and Glidden rules will hold, with the exception of the technical examination at the end of the run. Three trophies have been put up for the owners of the cars, and the Minneapolis *Tribune* has offered an additional one for the county commissioner of the county which has the best roads on the course. Since the announcement of this trophy a *Tribune* car carrying members of the state highway commission has been going over the course holding meetings with the county officials and the commercial clubs and other civic organizations. The route lies through St. Cloud, Alexandria, Fergus Falls and Pelican Rapids to Fargo, and return via Wahpeton, Wheaton, Benson and Litchfield.

AUTOISTS TO MANAGE HORSE SHOW

CHICAGO, Aug. 9—A most peculiar situation has arisen in regard to the horse show held annually by the Oak Park Horse Show Association. This is a fashionable suburban event of importance among western horsemen, but this year it will be conducted by a body of directors, each one of whom owns from one to five automobiles, but no horses.

PULLMANS LATEST TO ENTER MUNSEY TOUR

WASHINGTON, D. C., Aug. 9—While the Frank A. Munsey reliability tour project from Washington to Boston and return is just a month old, it has "caught on" in great shape. Several hundred columns of matter have been published about the tour in papers all over the country. During the first month fourteen entries were secured, the two latest being Pullmans, which were entered by the York Motor Car Company of York, Pa.

The work of blazing the route is well under way. All along the route the pathfinders have been received with the greatest enthusiasm, the automobile clubs in the various cities vying with each other in entertaining the Munsey scouts.

MINNEAPOLIS AWAITS A.A.A. SANCTION

MINNEAPOLIS, MINN., Aug. 9—Everything is in readiness for the annual reliability run conducted by the *Tribune* except the A. A. A. sanction, which Chairman Hower has not yet issued. The date is but a week off—August 17-18—and meanwhile the rules and entry blanks are held up. The route chosen this year by the officers of the Minneapolis Automobile Club takes the cars to Duluth and return, 186 miles each way, in two days. The roads afford all sorts of going, from good dirt to clay hills, deep sand and corduroy. The Minneapolis dealers are preparing for a strenuous test.

Interesting Summer Session of the S·A·E·

President Hess Led in an American Locomotive

A Studebaker Contingent.

Winton Six Had a Load

Among Those Present

CHICAGO, Aug. 7—The Summer convention of the Society of Automobile Engineers concluded at two o'clock this afternoon after a two-day session particularly valuable because of the nature of the papers read and the discussions which followed their reading. It was impossible to reach the paper on the testing of a 20-horsepower Franklin air-cooled motor, and this has been held over until the next meeting, as was also a paper by President Henry Hess.

Thursday morning the fifty-odd members soon adjourned and made the 51-mile trip to the Algonquin hill-climb, the engineers being among the most interested spectators of the event.

Friday morning the real convention opened, President Hess reading an invitation from John O. Heinze, inviting the society to Lowell, Mass., during the stock chassis races.

The first paper considered was entitled "Commercial Test of a Pierce Water-Cooled Motor," and was read by Prof. R. C. Carpenter, of Cornell University, though prepared by J. A. Luhrnan and J. G. Woodworth, of Cornell, under the supervision of the professor. The reading was prefaced by a series of screen views showing the construction of the Pierce six-cylinder motor, and was followed by an illustration of the manograph and a brief description of its advantages and shortcomings.

An equally interesting paper was "Some Points in the Operation and Care of Vehicle Batteries," by H. M. Beck; this paper included information about the ampere-hour meter which has been introduced during the present season and is meeting with much favor as an adjunct to the meters on an electric vehicle. The focal point of the paper consisted chiefly in the attention that should be given to a battery before it finally collapses, which is of paramount importance in that it is difficult to detect the ills of a battery because of its apparent simplicity. The discussion on the paper was particularly interesting, Frederick J. Neuman of the Woods Company, Chicago, taking the view that the testing of storage cells by the hydrometer is more reliable than that of the ampere-hour meter. Mr. Neuman, while recognizing the benefits of the ampere-hour meter, was afraid it might be too generally depended upon to the damage of the battery. Mr. Beck, in reply, took the stand that the ampere-hour meter was not looked upon as a cure-all for storage battery conditions, but served a useful purpose in that it is a quick method of knowing the exact charged or discharged condition of the battery.

Frank H. Lloyd read a short paper on "Lubricating Oils," in which attention was drawn to the vast varieties of oil. He compared the crudes of the different states and drew attention to the different qualities possessed by each one.

Secretary Alex Churchward's paper on "Energy and Consumption of Commercial Vehicles," consisted of a vast amount of invaluable data on the loss of power due to tires, transmission losses, road resistances, wind resistance, grades, springs, using direct gear ratios, stops made during the day and the methods of acceleration. Secretary Churchward also read a paper prepared by H. S. Baldwin on the "Electric Cradle Dynanometer" used for testing gasoline engines.

During the stay of the engineers in this city they were entertained by F. J. Neuman, of the Woods Vehicle Company. The majority of the members made their headquarters at the Illinois Athletic Club, where the Friday morning session was held. In the afternoon upwards of a score accepted the invitation of the Pullman Palace Car Company to visit the factories at Pullman, Ill. Saturday morning the sessions took place at the South Shore Country Club in Jackson Park, one of the show places of the city. After the adjournment at this afternoon a luncheon was served at the club by the Woods Company.

OPERATION AND CARE OF VEHICLE BATTERIES*

By H. M. BECK

WITH the rapid increase in the number of electric vehicles, the question of the proper operation and care of the storage battery becomes one of increased importance, as the best vehicle will not run if the battery goes wrong. While under normal conditions, the care of a battery is a comparatively simple matter, it must not on this account be entirely overlooked, and unfortunately, there has been some tendency recently, to minimize the actual attention required. This policy is not new, having been tried in other lines of battery work and, if continued, is sure to result disastrously. Why not rather admit that a certain amount of attention is required and insist on it? The best battery can be ruined in a comparatively few charges or discharges, where it would have given a long life with proper treatment!

The instruction books furnished by the manufacturers go into the operation and care of vehicle batteries very completely, and as they have been revised from time to time, one of them now being in its sixteenth edition, they are up to date. It will not be necessary, therefore, to go into many of the details of operation, but there are certain points which are either frequently misunderstood, or else on which it would be well to lay special emphasis, as their importance has apparently not been appreciated.

A storage battery is chemical in its nature, rather than mechanical, and must not, therefore, be confused with mechanical apparatus. The latter gives much more marked warning when it requires attention, and the fact that a battery may be apparently operating perfectly when it requires attention, is responsible for a great deal of battery trouble. When a battery finally breaks down, permanent injury has been done, and while it can generally be doctored back into shape, it cannot be made to give the life it should have given. In probably no line of technical work is prevention rather than cure of so vital importance.

Unfortunately the chemical theory of the storage battery has never been definitely settled, but an approximate idea of what goes on during charge and discharge can be easily stated.

A storage battery from an elementary standpoint consists of two or more plates, positive and negative, insulated from each other and submerged in a jar of dilute sulphuric acid. The plates consist of finely divided lead known as the active material held in grids which serve both as supports and as conductors for the active material. The active material being finely divided, offers an enormous surface to the electrolyte and thus electro-chemical action can take place easily and quickly. Two plates such as described, would have no potential difference, the active material of each being the same. If, however, current from an outside source is passed between them, one, the positive, will become oxidized, while the other remains as before, pure lead. This combination will be found to have a potential difference of about two volts, and if connected through an external circuit, current will flow. During discharge, the oxidized plate loses its oxygen and both plates will become sulphated until, if the discharge is carried far enough, both plates will again become chemically alike, the active material consisting of lead sulphate. On again charging, the sulphate is driven out of both plates and the positive plate oxidized. This cycle can be repeated as often as desired until the plates are worn out. Thus charging and discharging simply results in a chemical change in the active material and electrolyte, and the potential difference between the plates and capacity is due to this change.

In taking care of a storage battery, there are four points which are of the first importance:

1st—The battery must be charged properly.

2d—The battery must not be overdischarged.

3d—Short circuits between the plates or from sediment under them, must be prevented.

4th—The plates must be kept covered with electrolyte and only water of the proper purity used for replacing evaporation.

While as already stated, it is impossible to give an accurate formula for the chemical changes which take place in a storage battery during charge and discharge, certain facts dependent upon these are well established and are used as a basis for operation. These are the following:

Voltage—During charge, the voltage of a battery gradually increases until the cells are fully charged, but it will then come to a standstill and will not rise any higher, no matter how long the charge is continued. The maximum voltage thus reached is not a fixed point, varying widely at different times, depending upon the age of the battery, the temperature, the strength of the electrolyte and the charging rate.

During discharge the voltage falls, and if the discharge were carried far enough, it would reach zero, but experience has shown that this point is much too low for safety, resulting in the rapid destruction of the plates.

Specific Gravity—Due to the fact that during discharge the active material of both plates becomes sulphated, the specific gravity of the electrolyte falls. During charge the reverse process goes on, the sulphate is driven out. and the specific gravity of the electrolyte rises. As with the voltage, the gravity will rise gradually during charge until all the sulphate is driven out of the plates, but will then show no further increase, no matter how long the charge is continued. The maximum gravity thus obtained is also a variable figure, depending upon the temperature of the electrolyte as well as upon the actual amount of acid and water present in the cell.

The fall in gravity is almost proportional to the ampere hours discharge. In other words, specific gravity readings can be used as an ampere hour meter, but unfortunately, gravity readings are difficult or disagreeable to obtain in the case of vehicle batteries, so that this check on the discharge is not frequently used.

Gassing—Until nearly charged, the plates in a storage battery should absorb the energy put into them with little or no gassing. When they are nearly charged, the energy instead of being stored, shows itself in the form of more or less gassing, the amount depending upon the rate of charge. During discharge a cell should never gas. If it does so, it is an indication that it has been run down much too low and needs immediate attention.

Of the above indications, the first two, voltage and gravity, are those most commonly employed in operating. Gassing, while of great assistance as a guide or warning, cannot be depended upon for accurate results, and is only used when nothing but the most crude methods of operation are practical.

Either voltage or gravity readings alone could be used, but as both have advantages in certain cases, and disadvantages in others, it is advisable to use each for the purpose for which it is best fitted, the one serving as a check on the other.

Voltage has the great disadvantage in that it is dependent upon the rate of current flowing. Open circuit readings are of no value, as a cell reads almost the same discharged as it does charged. On the other hand, a voltmeter is a very easy instrument to read and may be located wherever desirable.

Specific gravity readings are almost independent of the current flowing, but the hydrometer is difficult to read, not very sensitive and the readings must be taken directly at the cells.

Charge—In the case of the pasted type of plates used almost entirely in vehicle service, experience has shown that the manner of charging has much to do with the life of the plates, and on this account it is sometimes stated that the life of a vehicle cell is proportional to the number of charges, rather than the number of discharges. On this account, it is wise to charge the cells as moderately as practical. On the other hand, it has been found that if the plates are to be kept in good condition, it is necessary to occasionally charge them to a maximum,

*Paper presented at the semi-annual meeting of the Society of Automobile Engineers, Chicago, Aug. 5-7.

thus reducing all the sulphate. Also, the different cells of a battery work as independent units, and while their efficiencies are approximately the same, there is generally some slight variation, which, if the cells are charged on a very efficient basis, will sooner or later cause irregularity, the cells with the lowest efficiency dropping behind. It is necessary, therefore, occasionally to even them up or the low cells will get in trouble. To meet these conditions, charges are divided into two classes—regular charges which should be as efficient as possible, and overcharges given at stated intervals, which are carried to a maximum voltage and gravity, and intended to reduce all the sulphate in plates and even up any irregularity in the cells.

Initial Charge—New batteries are usually received in a charged condition, but when this is not the case, the plates being shipped dry, or where the battery has been taken out of commission, it requires an initial charge before it is ready for service. This charge is not a complicated matter, but requires considerable time, frequently over 100 hours, and there is a very general tendency to cut it short. When the initial charge is not complete, the plates will not be properly formed, a certain amount of sulphate will remain in them which will produce local action and the capacity and life of the cells will be materially reduced.

In regular operation it is well to charge at the lowest possible rate. A large part of the wear on the plates is caused by the gassing, and the amount of gassing is reduced by a lower rate of current. Since the gassing occurs almost entirely near the end of the charge, it is especially important that the charging rate be low at this point, so that when the available time is limited, the necessary number of ampere hours can be gotten into the battery with the least possible wear by having the current rate high at the beginning of the charge and low at the end.

There is one point in connection with the charge which should be especially emphasized, namely, that the final voltage corresponding to a full charge is not a fixed figure, but varies widely, depending upon the charging rate, the temperature, the strength of the electrolyte, and age of the battery. For this reason, charging to a fixed voltage is unreliable and likely to result disastrously. The charge should be continued until the voltage or gravity cease rising, no matter what actual figures are reached. Old cells at high temperatures may not go above 2.4 volts per cell, whereas if very cold they have been known to run up to three volts.

The points to be especially emphasized in connection with the charge are:

First—On regular charges keep the rates as low as practical and cut off the current promptly. It is preferable to cut off a little too soon rather than to run too long where there is any question.

Second—Overcharges must be given at stated intervals and continued to a complete maximum. They should be cut off at the proper point, but when in doubt it is safer to run too long rather than to cut off too soon.

Third—Do not limit the charge by fixed voltage.

Fourth—Keep the temperature within safe limits.

Discharge—The discharge largely takes care of itself, except that a battery should not be run down below its voltage limit. The rate of current has very little effect upon the life of the plates, provided the discharge is not carried down too far. Where a battery is completely discharged, it should be charged as soon as possible, and if it has been run down too low, the charge should be continued to a maximum similar to the overcharge.

Ampere-Hour Meter—Many attempts have been made to develop apparatus which would automatically show the charge and discharge of a storage battery, but these have either been based on the wrong principles, or else the instruments would not stand the wear and team to which they were subjected, and they have therefore not proved satisfactory. Within the last year or so, however, a mercury type ampere-hour meter has been placed on the market, designed especially for battery use, and so far the results obtained have been very promising. This meter is equipped with a large dial and a pointer which can be set by hand to any point desired. This pointer revolves in one direction during charge and in the opposite direction during discharge, and registers directly the ampere-hour output or input to the battery. The mercury in which the armature disk is submerged acts as a dash-pot, and seems to be very effective in damping the vibrations and jolts which such a meter has to stand.

During discharge the meter shows directly what capacity has been taken out, so that it is a simple matter to determine what is left in the battery. For charging the procedure is somewhat more complicated, although not seriously so. It is necessary to charge a battery for from 15 to 20 per cent. more ampere hours than are discharged in order to make up for the losses in the battery. The method used to accomplish this is to move the pointer ahead the proper number of ampere hours just before charging, then charge until the pointer comes back to zero. The meters are equipped with an electrical contact at the zero point, which can be made to automatically open the circuit if desired. As will be seen, this considerably simplifies the handling of the charge, but there is one point which must not be overlooked, and which should be strongly emphasized, namely, that the efficiency of a battery varies with the amount of work it does, being much lower for light work than heavy. In fact, as long as in commission, the battery needs regular charges, even if it does no work at all; in other words, its efficiency would then be zero. This condition can be handled in several ways. Under average conditions, it is probably safe to charge by the ampere-hour meter for a set period, say two weeks, provided at the end of this period the battery is given a regular overcharge. An alternative method is to give an additional charge once a week by the meter of whatever number of ampere hours is found necessary to keep the battery up. The regular bi-weekly overcharge will probably be found to be the safer method, especially in private service where the conditions are so variable, but whatever method is used, too much emphasis cannot be laid upon the fact that if a battery is to be kept in good condition, in addition to the ordinary charges with the ampere-hour meter, regular overcharges must be given. The meter certainly gives promise of reducing the amount of attention a battery requires, but the danger is that it will, therefore, be assumed that it will eliminate all of it.

Short Circuits—Short circuits between plates are largely eliminated through the use of the wood separator. This point, therefore, does not need any special attention beyond that of seeing that the separators are in good condition when installed. With the sediment under the plates, however, the case is different. It is a natural tendency to wish to run a battery as long as possible before putting it out of commission for overhauling. The result is that very generally the sediment is allowed to get up to the plates before the battery is washed. When the sediment reaches the plates, there is a discharge of wasted current through it, which in turn necessitates that the cell be given more charge in order to hold it up, and the extra charging again throws down still more sediment. Further, the sediment become sulphated and, by local action with the active material of th plates in contact with it, causes the active material to become sul phated, which again increases the tendency to washing out The result is that the plates begin to lose their active materia rapidly if the sediment is allowed to collect until it reaches them and it is, therefore, evident that if a battery is to give its norma life, it is absolutely essential that the sediment be cleaned out before, and not after, it reaches the plates. The rate at which th sediment collects, depends largely upon the way a battery i handled, and it is, therefore, necessary to determine this rate fo each individual case. A cell should be cut out after, say, fift charges, the depth of sediment measured and the rate so ob tained used to determine the time when the battery will nee cleaning. As there is apt to be some variation in the amount c sediment in different cells, and as the sediment is thrown dow more rapidly during the latter part of a period than at the h ginning, it is always advisable to allow at least ¼-inch clearance. If the ribs in the bottom of the jars are 1¾ inches high, figure on cleaning when the sediment reaches a depth of 1½ inches.

Before dismantling a battery for "washing," if practical, have it fully charged. Otherwise, if the plates are badly sulphated, they are likely to throw down considerable sediment on the charge after the cleaning is completed.

There have been a great many complaints of lack of capacity from batteries after washing. Almost without exception this is found to be due to lack of a complete charge following the cleaning. The plates are frequently in a sulphated condition when dismantled and in any case are exposed to the air during the cleaning process, and thus lose more or less of their charge. When reassembled, they consequently need a very complete charge. and in some cases the equivalent of the initial charge. and unless this charge is given the cells will not show capacity and will soon give trouble again. This charge should be as complete as that described elsewhere in connection with the initial charge.

"Flushing," or replacing evaporation in cells with electrolyte instead of water, is a most common mistake. The plates of a storage battery must always be kept covered with electrolyte, but the evaporation must be replaced with pure water only. There seems to be more or less general tendency to confuse the electrolyte of a storage battery with that of a primary cell. The latter becomes weakened as the cell discharges and eventually requires renewal. With the storage battery, however, this is not the case, at least to anything like the same degree and unless acid is actually lost through slopping or a broken jar, it should not be necessary to add anything but water to the cells between cleanings. Acid goes into the plates during discharge. but with proper charging it will all be driven out again so that there will be practically no loss in the specific gravity readings, or at least one so slight that it does not require adjustment between cleanings. Thus, unless some of the electrolyte has actually been lost, if the specific gravity readings are low, it is an indication that something is wrong, but the trouble is not that the readings are low, but that something is causing them to be low, and the proper thing to do is to remove the cause and not try to cover it up by doctoring the indicator. The acid is in the cells and if it does not show in the readings, it must be in the form of sulphate, and the proper thing to do is to remove the cause of the sulphation, if there is one, and then with proper charging drive the acid out of the plates and the specific gravity readings will then come back to the proper point. The too-frequent practice in such cases is to add electrolyte to the cells in order to bring up the readings. which, as already explained, are only the indication of the trouble. and this further aggravates the condition. until finally the plates become so sulphated that lack of capacity causes a complaint. This practice of adding electrolyte to cells instead of water seems to be becoming more and more common. In general, it is much the safer course to assume that the electrolyte is all right, and look for trouble elsewhere, than to attempt to doctor it by the addition of more acid, and a great deal of trouble today is the result of a misunderstanding of this one point.

The treatment required for bringing a low cell or battery back into shape, while quite simple, is one of the most misunderstood parts of battery operation. The causes of low cells may be very varied, but the results produced and consequently the treatment required, are not so varied. The general procedure is as follows:

First—Restore the cell mechanically.

Second—Renew the electrolyte if there is any question as to its purity.

Third—Restore the cell electrically by charging.

Before dismantling a cell, if practical, have it fully charged: the mechanical restoration then simply covers the operation of examining the cell and putting it as nearly as possible back into its original condition. This should not be difficult for anyone who is familiar with the assembly of the elements.

Where there is any question as to its purity, the electrolyte should be renewed, as the expense is not great in the case of the small cells used in vehicle service, and it would hardly pay to have an analysis made. Where any considerable amount of electrolyte is under suspicion, the manufacturers will gladly analyze the same. It is well to always have the water used for replacing evaporation and new electrolyte, unless furnished by the battery manufacturers, tested.

The most marked effect of an impurity is to cause the plates to become a bad color, the cells to become inefficient electrically and, in extreme cases, the plates may be ruined.

When the electrolyte is renewed, the jar and plates should be thoroughly washed and the new electrolyte should be of about the same strength as that renewed, in order to allow for any acid which may be in the plates.

The electrical restoration has been probably the greatest stumbling block, and largely through lack of understanding, as this operation consists in simply charging the cell until a maximum voltage and gravity are reached. The common mistake is to cut off the charge before it is complete, in which case, the plates, being still sulphated, will not show capacity and are likely through local action to soon get into bad condition again.

With the possible exception of trouble due to an impurity, it can be generally stated that chemically the final condition requiring treatment is abnormal sulphating, and even where an impurity is present in the electrolyte, its action is assisted by sulphating. It should be understood that sulphating is a normal as well as an abnormal process in the charge and discharge of storage batteries, and the difference is in the degree, not the process. The abnormal condition is that ordinarily referred to by the term. In normal service, sulphating does not reach the point where it is difficult to reduce, but if carried too far the condition becomes so complete that it is difficult to reduce, and injury results. A very crude method of illustrating the different degrees of sulphating is to consider it as beginning in individual particles uniformly distributed throughout the active material. Each particle of sulphate is then entirely surrounded by active material. The sulphate itself is a non-conductor, but being surrounded by active material the current can reach it from all sides and it is easily reduced. This is normal sulphate. As the action goes further, the particles of sulphate become larger and join together and their outside conducting surface is greatly reduced in comparison with their volume, so that it becomes increasingly difficult to reduce them and we have abnormal sulphate.

The general cure for sulphating is charging, so that a cell having been mechanically restored the electrical restoration consists simply in the proper charging. Sulphate reduces slowly and on this account it is a good plan to use a rather low current rate. High rates cause excessive gassing, heating and do not hasten the process appreciably, so that it is the safer as well as the more efficient plan to go slowly. A good rate is about one-fifth normal. The length of charge will depend upon the degree of sulphating. In one actual case it required three months' charging night and day to complete the operation, but this was, of course, an exceptional one. The aim should be to continue until careful voltage and gravity readings show no further increase for at least ten hours and an absolute maximum has been reached. In serious cases it may be advisable to even exceed this time in order to make absolutely sure that all sulphate is reduced, and where there is any question it is much safer to charge too long, rather than to risk cutting off too soon. A partial charge is only a temporary expedient: the cell, being sulphated, will drop again.

Since the specific gravity readings are affected not only by the charge, but also by the evaporation and changes in temperature, it is advisable, where an absolute maximum is to be reached, to eliminate these. The evaporation should be replaced with sufficient frequency to keep the electrolyte accurately at a fixed height above the plates. In this way water is added so frequently that very little has to be added at any one time, and the effect on the specific gravity readings is negligible. The temperature variations are eliminated by reading the temperature of the electrolyte, when specific gravity readings are taken, and correcting the latter to some standard temperature, such as 70° F

This correction is made by adding one point (.001 specific gravity) for every three degrees above 70° F. and subtracting one point for every three degrees below 70° F.

When the charge is complete the specific gravity of the electrolyte should be adjusted to the proper point and the cell is ready for service. Where there is time, and the facilities are at hand, it is a good plan to take a test discharge in order to make sure that everything is all right.

Failure in the restoration of low cells is probably more often due to cutting off the charge too soon than to any other cause, and from the troubles which are being reported this point evidently needs to be brought out more strongly.

In closing, a word or two about the vehicles themselves. As manufacturers, we wish to admit without argument that the battery is the most important part of the vehicle, but, on the other hand, we would like to protest against the frequent practice of blaming the battery for everything that goes wrong. The battery is rated in ampere hours, not mileage, and when the mileage of a vehicle falls short, trouble should be looked for in the vehicle as well as in the battery. Batteries are regularly rated at their four-hour discharge rate, this being about an average running rate for vehicles. The capacity, however, varies widely with different discharge rates, decreasing as the rates increase, so that anything which causes the vehicle to consume more current will more than proportionately reduce its mileage. For example, suppose that, due to inefficient tires, poor bearings or binding brakes, a normal current of 20 amperes is increased to 30 amperes. If the ampere-hour capacity were still the same, and there were no other losses, the mileage would be reduced about one-third. This increases in current, however, reduces the actual capacity of the battery by about 10 per cent. The average discharge voltage is also reduced and the drop in wiring of the vehicle is increased, so that the watts delivered to the motor are still further reduced, and finally the motor itself is somewhat less efficient at the higher rate, so that the net result is that the mileage of the vehicle, instead of being reduced by one-third, is actually cut down by about one-half. It is thus evident how important it is that the vehicle be kept in the best of condition.

As has already been stated, no attempt has been made to cover many of the details of battery operation, but rather to emphasize and explain some of the most common errors found in the handling of the vehicle batteries of to-day, and of these probably that which should be brought out most forcibly is the matter of flushing cells with electrolyte instead of water. Keep the plates covered with electrolyte, but use only pure water, not acid, for replacing the evaporation.

ON LUBRICATING OILS AND THEIR CHARACTERISTICS*

By FRANK H. FLOYD.

IMPORTANT POINTS respecting the use of oils are as follows:

That your cars are all carefully tested before placing them in the hands of the purchaser, and are in first-class working shape.

That it is well to exercise careful judgment in purchasing oils, for their lubrication, that the wear and tear may be prevented.

That oils are usually sold under brands, and mean nothing.

That it is the property tests of an oil that determines its value as a lubricant.

That in analyzing numerous brands of oil on the American market the writer finds that they are strictly hydrocarbon oils, fractional distillates of crude petroleum, but of various specifications.

Fractional distillates are the different portions that are evaporated from crude petroleum by the refiner.

Gasoline, from 68 to 87 gravity, naphtha 58 to 60 gravity, kerosene, 46 to 48 gravity; miners' oils 38 to 49 gravity, light lubricating 33 to 35, medium heavy 22 to 31, heavy oils, 18 to 27 gravity, are fractions. True, oils are treated, filtered, etc., but in the rough they are parts of the crude.

That crude petroleum from different states, different wells, produces lubricating oil of entirely different properties under the same methods of refining. There is a choice.

That hydrocarbon oils employed in gas engine lubrication, are by nature composed of hydrogen and carbon.

That the weight of oil is controlled largely by the amount of carbon in composition. That in practice the heat generated in gas engine cylinders is sufficient to cause all oils to evaporate and burn to a greater or less extent.

That in evaporating, and burning, the hydrogen is driven off by the heat, leaving the carbon to precipitate or pass off with the exhaust.

That there are no oils that will not deposit carbon when they burn, and no oils that will stand the high temperature at the point of explosion without burning.

That water and air cooling keeps the temperature of the metals down to a practical lubricating basis.

That oils of light weight (high gravity) contain less carbon in composition than oils of low gravity (heavy weight) and will deposit less when they burn.

That the evaporative or flash test, and the burn test of an oil is important to consider in conjunction with gravity.

That high, evaporative test and light-weight oils, will be less affected by the cylinder heat and will deposit less carbon when they burn. The desideratum.

That the viscosity or body test of an oil should be considered in transmission and in lubricating journals and shafting in the crank case, but in cylinder lubrication it is impossible to refine high gravity, high evaporative test oils with little body.

If both are high, the body test will take care of itself.

That high-grade gas engine oils are filtered to lessen the carbon and the gravity is raised, and the weight reduced as well as the viscosity, but the fire test is not affected.

That the various colors of oil are due to the bleaching effect of the filtering medium.

That color alone is not an index in determining a good gas engine oil.

That the cold or fluid test is important to consider at low temperatures.

That manufacturers will do well to regulate the temperature of oil in the receiver to get a uniform flow in all seasons, and not necessitate a change in the specifications of the oil.

That finally, a good gas engine oil is one of high gravity (light weight) with a maximum high evaporative test, and a fluid oil at low temperatures.

That there are limitations in refining oils from high-grade crude.

That you should consider all of the property tests of an oil in purchasing and not pick out one as an index.

*Paper read at the semi-annual meeting of the Society of Automobile Engineers, Chicago, Aug. 5-7.

SPECIFIC WEIGHT AND BOILING POINT

It has been established that the specific weight of all samples of gasoline, as used in automobile motors, is not the same, on a basis of the boiling point of the respective products. If the boiling point is the same for two separate specimens, and the specific weight is different, herein lies proof of the futility of the use of hydrometers for the purpose of determining the real characteristics of the fuel. If all the products had the same specific heat, boiling point, specific weight and latent heat of evaporation, it would be easy enough to establish values of the relative evaporation, or with knowledge of the differences in the magnitudes, it would be possible to approximate the ends.

ENERGY CONSUMPTION OF COMMERCIAL VEHICLE*

By ALEX. CHURCHWARD

WHEN studying the performance of the motor vehicle, one of the most important items is the energy required per ton mile. We can rely upon the engine to give a certain horsepower output at a predetermined speed. Therefore, knowing the maximum horsepower output of the engine, we can readily determine what service the vehicle is capable of performing.

The horsepower required by a vehicle, however, is influenced by a number of factors, the principal ones being:

First: Tires—Ordinarily the standard vehicles are equipped with either pneumatic or solid tires, pneumatic on the lighter vehicles, such as runabouts, coupés and broughams. Solid tires on some runabouts and cabs, and nearly always on commercial vehicles.

The tractive effort of pneumatic tires on hard level asphalt varies from 15 pounds per ton for special tires designed for electric runabouts up to 35 pounds per ton for the standard type used on gasoline touring cars.

The tractive effort of pneumatic tires is also greatly affected by the air pressure, increasing rapidly as the air pressure is reduced.

The tractive effort of solid tires on hard level asphalt varies from 18 pounds to 26 pounds per ton, depending upon:

(1) The diameter of driving wheels.
(2) Revolutions per minute.
(3) Load in pounds, per square inch or pounds per inch width.
(4) Composition of the compound used.
(5) Method of attaching tire to wheel rim.

Second: Controlling Apparatus—The efficiency depends a great deal upon the type of drive used, such for instance as:

(1st) The sliding gear with direct drive on the high through a bevel on live rear axle.

(2d) Sliding gear with direct drive on high through countershaft and chains to dead rear axle.

(3d) Sliding gear, not direct on high, and through countershaft and chains to dead rear axle.

(4th) Planetary with direct on high by means of bevel or chain to live rear axle.

(5th) Planetary to countershaft through chains to dead rear axle.

(6th) Friction gear to live rear axle through bevel or chains.

(7th) Friction gear to dead rear axle through chains.

(8th) Worm drive direct on high to live rear axle.

Some form of independent clutch being used on the 1st, 2d, 3d, and 8th.

Third: Transmission Losses—These include gearing or chain losses, and all bearing losses throughout the vehicle. Most vehicles to-day are built with anti-friction bearings throughout. Ball bearings should always be used in the countershafts; ball or roller bearings in the wheels. Personally, I prefer ball bearings throughout, and my experience has shown that ball bearings in the wheels are perfectly reliable when properly selected and correctly installed.

From countershaft to wheels the roller chain has proven itself satisfactory, but care must be taken in the selection of the make of chain, also the right pitch and number of teeth in the sprockets.

Fourth: Alignment of Axles and Driving Mechanism—Unless the alignment is perfect under all conditions of maximum stress, the energy consumption will be high. An axle sprung beyond the elastic limit by overloading may increase the energy consumption 10 per cent. to 15 per cent.

A vehicle that coasts freely may require too much power when the driving stresses are applied. Therefore, all parts must be in perfect alignment under all conditions to be met with in service.

Fifth: Correct Gear Ratio—Unless the gear ratio is correct for the average service the vehicle is called on to perform, the motor will either run at too high an average speed or the change gears will have to be used very frequently, which will tend to increase the maintenance of the vehicle when placed in the hands of a careless driver.

Sixth: Wheel Diameter—Small wheels will increase the energy consumption materially on the average roadbed, because, the smaller the wheel diameter the greater the vehicle vibration when going over an obstacle of a given height.

Seventh: Springs—The springs of a vehicle must be correctly proportioned and of suitable material; otherwise, there will be considerable movement of the vehicle body when going over uneven roads; this, of course, means energy consumed which cannot be restored.

Eighth: Road Resistance—The tractive effort of a vehicle will vary with the road surface as per table, taking the tractive effort of a vehicle on hard level asphalt as unity.

(1)	Level asphalt (hard)	1.00
(2)	Wood pavement	1.15
(3)	Level macadam	1.15 to 3
(4)	Plank road	.9
	Cobble stones	1.75
(5)	Good dirt road	1.10 to 2
(6)	Ordinary country road (dirt)	.2
(7)	Sand	.20

Ninth: Grades—The tractive effort due to grades must be added to the tractive effort for a given road surface. Example: 5 per cent. grade on hard level asphalt. Hard level asphalt 25 pounds per ton. 5 per cent. grade = 100 pounds per ton, due to grade alone. $100 + 25 =$ total tractive effort $= 125$ pounds per ton, total.

Tenth: Wind Resistance—Below 12 miles per hour the additional tractive effort necessary to overcome the wind resistance on heavy vehicles is comparatively small. But on the light high-speed vehicles, when running at speeds above 12 miles per hour, the wind resistance becomes quite a large factor.

Eleventh: Economic Speed—Taking everything into consideration, that is to say, life of engine, transmission, tires and maintenance of vehicle as a whole, experience shows that the following table is approximately correct:

Gross Weight.	Type of Tires.	Speed in M.P.H.
1,500 lbs.	Pneumatic.	20
2,000 "	"	20
3,000 "	"	18
4,000 "	"	16
2,000 "	Solid.	16
3,000 "	"	15
4,000 "	"	13
5,000 "	"	11
7,000 "	"	9
10,000 "	"	8
15,000 "	"	7
20,000 "	"	6

Twelfth: Stops—The number of stops per mile will have a considerable influence on the energy consumption of a given vehicle.

Thirteenth: Acceleration—It should never be too rapid; if it is, there is danger of damaging the engine or snapping a chain or gear. It can be seen from the preceding items that there are a great many factors which influence the energy consumption and, therefore, the performance of a commercial vehicle.

*Paper read at the semi-annual meeting of the Society of Automobile Engineers, Chicago, Aug. 5-7, 1909.

SOME COMMON KNOCKS AND SQUEAKS IN THE MOTOR

By STILLMAN TAYLOR

PERCHANCE the reader will smile at the above caption and incline to the belief that the following text is penned in jocund vein. This is not the case, however, the above heading merely expressing a common annoyance which is likely to happen to any motor-car. By "knocks and squeaks" is meant any unusual noises which may at any time develop in the engine, transmission, or running gear. Troubles of this kind vary greatly as to cause and location, but the effect is presented to the driver's notice in a more or less regular or irregular noise, heard above the vibration of the car. The usual purring vibration of a well-oiled and smooth-running motor is a sound with which every autoist soon becomes accustomed and if much driving is done, the ear becomes quite sensitive to other occasional and unusual noise of operation. Indeed, any unusual noise may be taken as an indication of trouble, and should be located without delay. To neglect this may result in serious injury to the car.

Knocking is a common occurrence and may be caused by several things, the sound being in the nature of a regular distinct rapping within the cylinder. Knocking may be due to too early ignition and will occur when the spark is advanced beyond the balanced center or working point. This will frequently be the case when the motor is running slowly, the early firing of the charge resulting in a back fire and knock, familiar to all autoists. If this is the seat of the trouble, the knock should cease when the spark is retarded to the normal point. A "rich mixture" will often produce a knocking noise almost identical with that produced by too early sparking. This is caused by the mixture burning too rapidly or too slowly. The remedy is quite as simple (if the supposition be correct), the mixture should be throttled or the tension of the auxiliary air-valve spring released to admit more air. Other causes of knocking within the cylinder are frequently traced to faulty lubrication or accumulation of carbonized oil. Sufficient cylinder oil is, of course, essential for proper lubrication, but if used excessively, the piston, cylinder walls and valves will quickly become coated with soot. Improper ignition or timing will also produce a popping noise, due in this case to the ignition taking place during the suction or exhausting strokes.

Not infrequently the knocking or pounding noise will, upon investigation, be found outside of the cylinder itself and the nature of the noise will indicate the probable cause. For instance, a heavy knock or pound is generally caused by pre-ignition, but may also be attributed to a loose main bearing, loose connecting-rod bearing, broken piston pin, or in less frequent instances, to a flywheel working loose on its shaft. A connecting-rod will sometimes work out of alignment with its crank-pin, and although not often sufficient to stop the motor, the matter should be attended to as soon as discovered.

Clicking in the Cylinders Is a Sure Source of Trouble—A continuous clicking, wheezing, or squeaking noise in the cylinder should be investigated, as it is a pretty sure sign of loose or worn piston rings. It is important to attend to this at once, as neglect may result in scoring the cylinder walls.

A puffing or cracking noise indicates that the compressed gas is escaping into the air and the leakage may be generally found to be caused by a leaky compression or pet cock or spark plug. If valve grinding has not been attended to, the leak may be in the valves which have become warped or pitted, and do not properly seat themselves.

Squeaking, grating, and rattling may be located by the character of the noise. A continuous squeaking or grating may be generally traced to a small bearing surface, while the occasional squeak is often found in larger surfaces, as cardan joints, lever connections, brakes and springs. If an investigation fails to locate the squeak in the transmission gear, the clutch collar should be examined. It should be noted, however, that a squeaking or other unusual noise is not always of a serious nature and may be frequently due to some little spring or other small part likely to be overlooked.

An instance of this kind occurred to the writer but a few days ago, when a squeak suddenly developed while returning from a short trip to the shore. We were running along on high gear when the squeak was first heard; not a loud noise, but an insistent squeak sufficiently loud to be heard above the purr of the motor and the subdued roar of the gears. We stopped the car and after looking over the important parts first, located the noise in an exhaust-valve spring, which had broken down just enough to work out of line and bear upon the valve-stem guide. A few drops of oil at once effected a cure.

The brakes are often a source of trouble and while it should be perfectly obvious to every driver and owner that these vital parts of a car should be frequently examined, that they may be properly adjusted and lubricated, it is not uncommon to find the brakes, of an otherwise well running and cared for car, in a bad state of neglect. If a squeak develops in the brakes, the trouble should be looked for in the drums which may need re-adjusting or a drop or two of oil.

INDIANA ADVANCING IN AUTOMOBILE PRODUCTION

INDIANAPOLIS, IND., Aug. 9—Indiana is rapidly coming to the front as an automobile-producing State, and although there is no immediate prospect of displacing Michigan from the front rank, still no mean number of cars will be built. Indianapolis alone expects to put out fully 10,000, and the record for the State no doubt will reach 25,000.

The organization of the Parry Automobile Company has been completed and the company has been incorporated with an authorized capitalization of $1,000,000. David M. Parry, the president of the company, has closed a three-year lease of the buildings of the Standard Wheel Company. These buildings are being equipped with the necessary machinery, and it is expected that the first Parry automobile will be finished about August 20. Other members of the Parry Company are Warren D. Oakes, William C. Teasdale, Jr., and Maxwell O. and Addison J. Parry.

In anticipation of increasing its output, the Overland Automobile Company is making extensive improvements and erecting new buildings that will cost $40,000. An assembling and upholstering department is now nearly finished and an enameling plant and a power plant will follow as rapidly as they can be built and occupied.

Much attention is also being given to extending the retail side of the industry. The Studebaker Automobile Company of South Bend, Ind., has organized a branch in this city, and for its occupancy is building a six-story garage and salesroom that will be finished about October 1. The building will cost approximately $100,000. Frank Staley will be manager. The Buick will also be taken care of by a branch house in the future. R. H. Losey, formerly president of the agent company, has been appointed manager. The Rider Lewis Automobile Company, which is moving from Muncie to a new and up-to-date plant located at Anderson, expects to turn out 3,500 cars next season, and has already received large orders. The new plant, with its improved facilities, would seem to allow of an output of this size or larger.

Helical Springs as Applied to Valves

Chapter VIII

POPPET VALVES are of two classes, one of which is automatic and the other positive, so called. In the automatic type of valve a spring is used exclusively and suction of the motor opens the valve against the pressure exerted by the spring. In positive (mechanical) valves the spring is used to close and a cam, in conjunction with a lift, is employed to open the valve against the pressure exerted by the spring.

Springs for automatic valves must necessarily be very delicate and so nicely poised that they will positively close the valve without at the same time requiring much suction pressure in opening. If a valve has an area of, say, 7.2 inches, and the suction pressure required to open it is limited to 1 pound per square inch the spring must not exert a pressure about 7.2 pounds. Since the pressure the spring will resist in opening must be very low if the motor is to deliver a fair measure of power it follows that the same spring will have but a limited ability to be displayed in closing the valve.

It is because of this limit, coupled with the uncertainties attending the use of springs, under the conditions governing motor work, that resort is had to the other plan in almost all motors, for if the valve is opened by means of a cam motion the strength of the sring may be very great relatively and in closing the valve the stronger spring will do the work in a shorter interval of time and with far greater certainty.

When automatic spring valves are used the valves are made as light as possible in order that a relatively weak spring will be efficient for the purpose. The same rule holds in the other system, for if the spring is over strong, which it will have to be if the valve is very heavy, the pressure on the cam face will be more than long life would seem to dictate.

In mechanical valve systems the limitations are not so close and the advantage of positive opening at a fixed relative time are very great, although it is of the greatest importance to so time the opening of the valve that the functions will be normal, and in the minds of some designers it is a question if positive opening even approximates the perfection which is theoretically true of the automatic type. As for holding valves open, surely the cam face may be made of the desired arc, and that the opening may be that due to the required lift is but a matter of conforming the cam to suit, remembering that the greater the lift the greater will be the travel, which is a matter to be considered when the spring is required to close the valve within a limited travel.

The best condition of closing will follow when the valve is light—lifts but little—with a stout "live" spring. Disregarding the design of the spring for the time being, the work it will have to do may be stated as follows:

Let

S = speed of the camshaft in revolutions per second.
W = weight of valve in pounds.
P = pressure of spring in pounds.
l = lift of valve in inches.
K = a constant = 30.
θ = face angle of cam, representing the angular movement.
y = another constant = 0.67 of the cam to induce a full lift of the valve.

When,

$$P = \frac{l(S \times k)^2 W}{y\theta^2}$$

Extract from Vol. I., Part II., Chapter VIII., of a set of books, in preparation, by Thos. J. Fay, covering all phases of automobiling, from the point of view of designers, constructors, and in actual service.

The angle through which the camshaft will rotate during the closing of the valve, which is the important matter, will by transposing the above formula be indicated as follows:

$$\theta = \left(\frac{l(Sk)^2 W}{yP}\right)^{1/2}$$

The difficulty attending the closing of valves under the conditions as above depicted are directly proportional to the weight and lift, but, unfortunately, as the square of the speed of the camshaft. That the valve should close quickly is an absolute necessity, and in order to do so it is proper to use a spring capable of accomplishing the task. Since springs do not remain always in the same state, due to the effect of work, heat, etc., as they are placed to serve, it is necessary to start out with a spring somewhat stronger than necessity would seem to indicate.

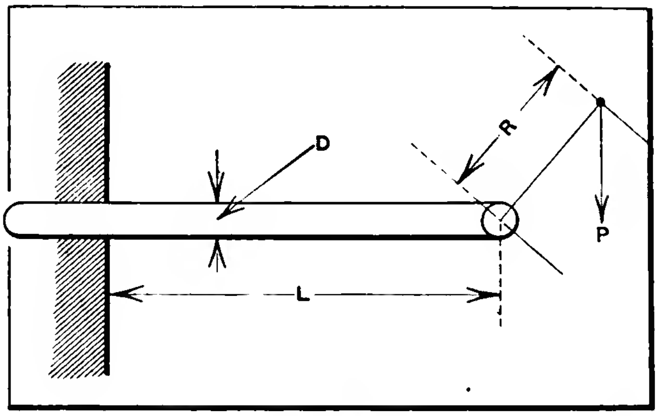

Fig. 1—Simple torsional member used in conjunction with the rational formula

Since, as the formula shows, the spring pressure required will reduce in proportion to the square of the angle of rotation of the camshaft during the act of closing, it follows that the difficulty will increase enormously as the angle is reduced. If, for illustration, a 10-pound spring will close a valve weighing 1 pound, lifting 1-10 of an inch within 40 degrees rotation, according to the formula, it will take a 40-pound spring to do the work within a 20-degree rotation of the camshaft. In practice springs used for this purpose on motors of moderate size, say, 30-40 horsepower, are usually capable of exerting from 35 to 45 pounds.

Theory and Design of Springs—For the convenience of practitioners a table has been compiled and is offered in which will be found most the sizes of springs which will be of use in automobile work. For the better understanding the rational formulæ of helical springs are given as follows:

Let

L = length of torsional member in inches.
D = diameter of the same in inches.
R = radius of the lever arm in inches.
J = polar moment of inertia.
P = pull in pounds on the arm at the end.
t = ultimate shearing strain in pounds per square inch.
e = distance in inches of the remotest fiber from the axis.

When,

$$P \times R = \frac{Jt}{e}$$

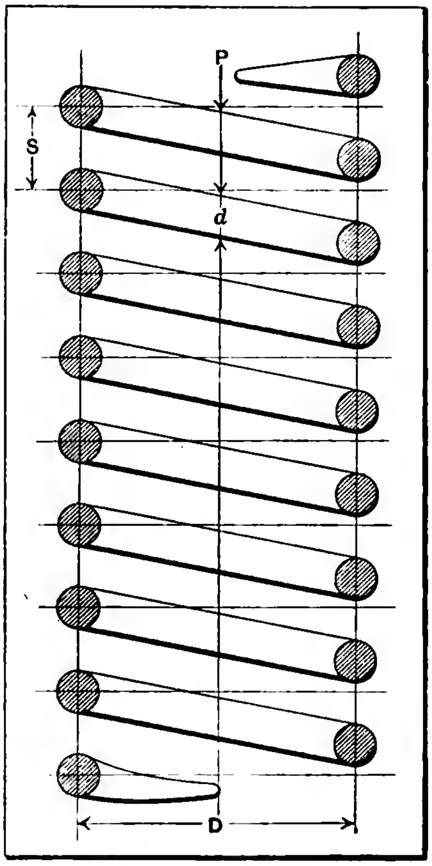

Fig. 2—Conventional spring as used in connection with poppet valves

This demonstration takes for its basis a straight round section, as illustrated in Fig. 1, represents diagrammatically the way in which torsional strains are set up in a member and it is true of springs as well as in other members which are not of such intricate shapes.

Torsional strains t will be due to the pull in pounds P at the radius in inches R at the end of the lever-arm and the resistance to this torsion will be offered by the shaft as measured in inches D, the length of which L represents the distance between the anchorage and the point of application to the lever-arm.

Since it is necessary to determine the extreme fiber strain due to torsion in order to be able to select a suitable grade of material and determine the diameter D, the exploration will involve considerations as follows:

(A) Find the maximum carrying capacity for a given diameter D.

(B) Ascertain the deflection due to the maximum load in view of the material to be used.

(C) Solve for the stiffness and deduct a coefficient of the same.

(D) In spring shapes, of the helical type, as well as in the straight member shown in Fig. 1.

Considering a helical spring, as illustrated in Fig. 2, all the turns are of the same diameter D and since the diameter of the wire is the same throughout, the several turns will be of the same strength. Fig. 3, on the other hand, is of the conical-helical type, and the ability of the respective turns will differ from each other, requiring that each turn, differing in dimensions, be considered and the mean found.

For the helical spring, in which all the turns are of the same diameter, the mode of application of the rational formulæ will be as follows:

Let,

D = diameter in inches measuring from center to center of the wrap.

d = diameter in inches of the round wire used.

P = weight in pounds either in compression or tension.

R, J, t and e as before taken.

When,

$$J = \frac{2\pi d^4}{64} = \frac{\pi}{32} \times d^4; \qquad e = \frac{d}{2} \text{ and } R = \frac{D}{2}$$

hence,

$$P = \frac{\pi}{8} \times \frac{d^3}{D} \times t$$

t = 64,000 (which is a fair average value for the ultimate shearing strain or torsional strain as in this case, when figured in pounds).

In a straight member, as depicted in Fig. 1, the torsional angle, α (alpha), depends upon the pull P; at the radius R, considering a given size and length of the member, which may be ascertained as follows:

$$\alpha = \frac{PR}{GJ} \times L$$

when,

α = alpha = angle of torsion.

G = modulus of elasticity for shearing = 10,660,000.

J = as before.

In applying this principle to the helical spring, instead of to a straight round member, proceed thus:

$$\alpha = \frac{2\pi R^2 N}{GJ}$$

The deflection of the spring will be due to P, and in magnitude is as follows:

$$q = R\alpha = \frac{2\pi R^3 N}{GJ} \times P$$

when,

$$J = \frac{\pi d^4}{32} \text{ and } R = \frac{D}{2}$$

extending,

$$q = \frac{8 D^3}{G d^4} \times P N$$

Involving the modulus of elasticity,

$$q = \frac{8 D^3}{10{,}660{,}000\, d^4} \times P N$$

simplified,

$$q = \frac{D^3}{1{,}332{,}500\, d^4} PN$$

Hence the value of P (maximum) substituting for q will be:

$$P = \frac{25{,}120}{1{,}332{,}500} \times \frac{D^3}{d} \times N \qquad e = \frac{D^3 N}{53\, d}$$

The table of springs is compiled on a basis of 10 coils to the spring in each case, hence the (maximum) deflection allowable will be:

$$q = \frac{D^3}{5.3\, d}$$

Since, in many cases it is desired to have more or less than ten coils to the spring, it will be necessary to proportion the deflection allowable to suit the number of coils to be used; this is a simple thing to do since the value of q will be in direct proportion to the number of coils in the spring.

In the table a coefficient of stiffness is given for each spring; this coefficient is calculated as follows:

$$q = \frac{PN}{32c}$$

whence,

$$32c = 1{,}332{,}500 \frac{d^4}{D^3}$$

and,

$$c = 41{,}641 \frac{d^4}{D^3} = \text{coefficient of stiffness.}$$

Since the value of the coefficient of stiffness is dependent upon the diameter of the wire and the diameter of the coil, it gives a true measure of the stiffness of the spring for a given number of coils and a given load in pounds. It is also true that the deflection is in the inverse ratio of the coefficient of stiffness.

In comparing different springs with each other, proceed thus:

$$q = \frac{1}{32} \text{ and as } q : \frac{PN}{32c} :: c : P$$

In this way the weight in pounds, necessary to deflect each coil 1-32 of an inch, is determined.

The values given for P are maximum, and if the work is incessant at the maximum, it is well to use a spring of greater ability in order to assure long life. In the application of springs to cylinders it is of the greatest importance to protect them from undue heat in order that the temper will not be drawn, and since every spring will "set" shortly after it is put to work, if the service is near the value of P maximum an allowance for set should be made.

TABLE OF DIMENSIONS AND ABILITY OF HELICAL SPRINGS

[illegible]	Diameter of Steel Wire — d.																			
	1/16"		1/8"		3/16"		1/4"		5/16"		3/8"		7/16"		1/2"		9/16"		5/8"

$$\frac{A}{C} \quad B$$

A = rated capacity in pounds.
B = deflection in inches with 10 coils.
C = the deflection of a spring with any number of coils will be:

$$x = \frac{PN}{32\,C}$$

when N = number of coils, and C represents the coefficient as given in the table.

Much Depends Upon Proper Selection of Springs—Glancing at the table it will be to note that several selections of springs may be made considering a given rating in pounds. All that is necessary is to alter the number of turns in such a way that the rating of the spring, so altered, will be the same as another spring having ten turns. That the result will be so good is a matter to be contested. In general the best spring will be the one which responds quickest, and to afford this result it is necessary to select a size of wire offering this property. In practice it is the custom to select a size of wire ranging between 1-8 and 3-16 inch, and it is not uncommon to note center to center diameters of even 2 1-4 inches. The number of turns are then regulated to afford the requisite rating of the spring holding the torsional stresses to a point at least as low as the allowance in the table, remembering that is on a basis of ten turns of wire.

A 1-8x2-inch round wire, according to the tabular values, will have an ability of 24.5 pounds. This spring would scarcely be strong enough for the average motor considering the effect of service, although from calculations it would seem to be amply strong for the purpose if the valve weighs less than 1 pound and if the lift is within 3-16 inch.

If a spring of 2-inch coil with ten turns is made of 3-16 wire it will have an ability of 83 pounds, which will be double the strength usually found in motors, and some size of wire for a given diameter and number of turns ranging between 1-8 and 3-16 inch would have to be used, thus requiring the use of formula in the careful determination of the size. True, it would be possible to use the 1-8-inch diameter wire, holding to 2 inches diameter of the coil, and the stiffness would be increased by reducing the number of turns of the coil. This would lead to dangers, since the stresses in the extreme fiber of the wire would increase and the spring would also be less "smart" in the performance of its proper functions.

It is not always possible to employ ten turns of wire since in some designs of motors head-room is at a premium. In such cases it is possible, as a rule, to make the diameter of the coil greater and use a larger diameter wire with a less number of turns and in this way afford adequate spring action and keep within safe limits of the extreme fiber strain.

Danger in the direction of a sluggish spring lies in the use of a large size of wire of a small diameter of the coil, limiting the number of turns. This same effect will come if the material is inferior for the purpose and if heat from the cylinder draws the temper of the spring.

When a spring is made, the pitch of the turns is such that the amount of pressure it is safe for the same to withstand, if compressed (or elongated), the distance as fixed in the table, for the given sizes, so that in depicting the spring it is necessary to show the "free" length of the given number of turns and state the compressed position and the load the spring must sustain under when it is compressed the given distance. An allowance must be made for the lift of the valve, which will compress the spring to a further extent if the same is in compression, which is common practice.

A spring will do just the same amount of work in tension as it will in compression within the elastic limit and the difference lies in the pitch of the turns. If the spring is to work in tension it is customary to fix the pitch with but a slight clearance, whereas, if the same is to be in compression the pitch is established on a basis of slight clearance between turns when the spring is compressed to its maximum safe limit. By thus limiting the clearance of the turns the spring is afforded a measure of safety since it will not be possible to compress it beyond the safe limit; in tension it will not be possible to introduce an automatic safety feature by adjusting the pitch.

If the material of which a spring is composed is not up to a certain standard it will not perform in accordance with the conditions established by the formulæ as offered in this work, and since the formulæ is agreeable to materials which do abound in plenty, the proper course in such an event is to select suitable materials. Even if the material is suitable the method of winding the springs will affect the results since it is possible to take the life out of the steel, and in heat treatment in the absence of skill anything but good results may follow. Spring steel, high in carbon, is prone to deteriorate; since the high carbon is necessary, the manipulator must be capable.

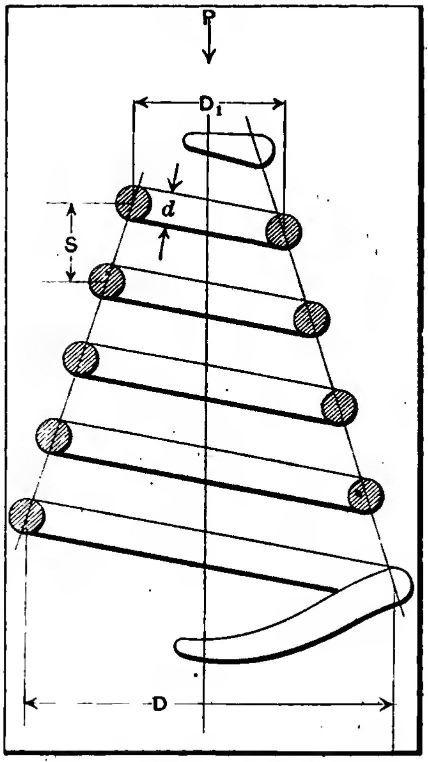

Fig. 3—Short (conical) helical spring for use in restricted space

LETTERS INTERESTING AND INSTRUCTIVE

USE OF GRAPHITE

Editor THE AUTOMOBILE:

[1,973]—Will you please give me some idea of the way to use graphite on an automobile engine. Should it be put into the lubricator or into the crankcase direct, or should it be used in some other way? A. B. SEE.

Bensonhurst, L. I.

Graphite should be mixed with the oil to go into the crankcase or splash system, and should never be put into the lubricator. The reason for this is that it (the graphite) seems to clog up not only the pipes leading to the bearings, but the moving parts of the pump as well. An excellent way to use it is to clean out the crankcase and then, when putting the oil back in or putting in fresh oil, use the graphite-oil mixture. To make this, add a teaspoonful of the purest, finest graphite obtainable to a gallon of oil. This sounds like a very small quantity, but it is a fact that a very small quantity is necessary. After mixing this very thoroughly (take plenty of time to mix it, as it is time well spent) pour it into the case. In actual running the graphite will reach the main bearings, which are the places where it does the most good, and then seems to give them a sort of very thin coating, which is glazed and which acts to protect the pins. A smaller quantity of the oil with graphite in it should be used than the ordinary clear oil. So, too, if the lubricator or pump is of such a construction that the graphite could be put into it with safety, the feeds can be reduced to about one-half of the amount usually used. That is, the addition of graphite to the oil allows of cutting the oil consumption in half, or of reducing the amount of oil used very materially. This, too, with very little graphite.

INSTRUCTION BOOKS

Editor THE AUTOMOBILE:

[1,974]—I am a new owner of a car and wish to familiarize myself with the component parts of an automobile, not alone the make I now have but other and different makes as well. So I would ask you where I can get descriptions of the parts, or more particularly, the repair and care of the parts of the other cars. F. H. GETMAN.

Brookville, N. J.

The very best way to get acquainted with the difference between the various makes of cars is to read—or, better, study—the car descriptions as they appear from week to week in the columns of THE AUTOMOBILE. This would insure your being up to date; that is, you would familiarize yourself with the cars as now built.

If, however, you did not care for this, and would just as soon learn the mechanism and the care of the same for old model cars, the plan will be to write to the companies issuing instruction books. These are usually illustrated with cuts of parts of the car, and tell in detail how to care for, and in some cases how to repair, the various parts. The following companies have issued instruction books of this sort: Pierce-Arrow Motor Car Company, Buffalo; Packard Motor Car Company, Detroit, Mich.; Peerless Motor Car Company, Cleveland, O.; Knox Automobile Company, Springfield, Mass.; Pope Manufacturing Company, Hartford, Conn., and Thomas B. Jeffery Company, Kenosha, Wis.

FIERCE CLUTCH REMEDY

Editor THE AUTOMOBILE:

[1,975]—Will you please tell me how to remedy the action of my clutch, which takes hold with a jerk when let into engagement, and seems to grab at all times. I have been told by friends that this is what is called a "fierce" clutch, but none of them suggested a remedy. PEARSOL SARGEANT.

New Rochelle, N. Y.

If you have described all of the sources of trouble the whole matter lies in the tension of the spring, this being adjusted up too tight. In other words, the spring is too strong for the work it has to do, and should be weakened by slacking off on the adjustment. This may or may not be done easily, but in any case should be done gradually, slacking off a very little each time, until you ultimately get it just right. Moreover, if, as your letter seems to indicate, you are not very familiar with the parts of the car, this will be an excellent opportunity to get acquainted.

If, on the other hand, there are other matters entering into the trouble that you have not told about, this method of fixing it may be all wrong. Thus, if the clutch acts fierce from oil on the leather, the way to fix that is to take it out and clean it thoroughly before returning it to place. Part of your trouble may be due to harsh leather, which is remedied by lubricating it thoroughly with castor oil. The symptoms of the first are noticed in slipping when the clutch is let in; that is, it does not take hold at once, and when it does the grip is not certain, so that a hard pull through sand or the like is liable to make it slip again. In any clutch trouble it is always well to look to the rivets which hold the leather to the clutch spider. If these project too far they are liable to catch in the metal of the female cone, scratching it and preventing the clutch from taking hold properly. After once well scratched the clutch never will engage properly until this surface is machined over again. On the other hand, it is well to know the material of which the rivets are composed, since copper and other soft metal rivets are easy to take out and replace, thus making a replacement of the clutch leather a comparatively easy job. If hard metal, such as steel or iron, be used for the rivets, changing leathers means a very hard job.

VARIOUS QUERIES

Editor THE AUTOMOBILE:

[1,976]—In the July 15 issue of "The Automobile" a description of the new Maxwell car is given in which a four-cylinder engine of 3 3-4-inch bore and 4-inch stroke is given as developing 22-horsepower at 900 revolutions. Now, the Ford of 3 3-4 diameter and 4-inch stroke is only rated by the makers at 16-horsepower at 1,400 revolutions. Can you give me any explanation of this?

Also, in the rating of the automobiles on the present Kansas City-Detroit races, the horsepower of the automobiles is given. What is the standard number of revolutions and how fast can a motor be run with safety and economy? Does this rate vary with different makes, and why?

I have a four-cylinder Ford Model N and it seems to give quite a little trouble in climbing hills, pounding if opened up, either spark advanced or throttle being opened. Can you explain the trouble? Would a too rich mixture cause pounding? Please explain the philosophy of pounding.

Now, in the combustion of gasoline, carbon and hydroben, how many units or atoms of oxygen are used in the consumption of each? Do they burn together or does the hydrogen burn first? In the combustion of a given number of atoms of oxygen with hydrogen, and also carbon in a given amount, which gives the greater number of heat units? Similarly, in the combustion of given amount of gasoline, say an ounce, how much oxygen in the form of air is needed, and how many heat units are produced?

As regards carbureters, can you give me a description of the various makes on the market and used on standard cars; manufacturers, with points of merit claimed by them and whose claims have been substantiated by actual tests, given in detail.

Are gasoline engines expressly made for a special number of revolutions; that is, is each engine adapted to a particular number of turns per minute so as to give the best results at that rate, and what is the reason that these conditions are produced?

Nichols, Conn. W. T. K.

The statement as to the ability of the Maxwell engine was furnished us by the manufacturers. As to the Ford rating, your figures are in error, for the latest Ford catalogue rates the 3¾ by 4-inch engine at 20 horsepower. The generally accepted formula for rating engines is that advanced several years ago by the Royal Automobile Club of Great Britain, and adopted about a year ago by the A. L. A. M., from which it has now come to be called the A. L. A. M. formula. This is: Bore of cylinder squared, times the number of cylinders, divided by 2.5; or, simplified for a four-cylinder engine, bore squared times 1.6. This gives for the size of cylinder used on both Maxwell and Ford cars the rating 22½ horsepower, so that both makers are well within the power rating.

While this formula apparently does not consider the stroke or speed, it actually is based on an average piston speed of 1,000 feet per minute. Now, since the revolutions per minute times two equals the number of strokes per minute, and this times the stroke in feet equals the piston speed per minute, this may be put in the form:

$$\frac{\text{Feet per minute}}{2 \times \text{stroke in feet}} = \text{r. p. m.}$$

So, by substituting for the item feet per minute 1,000, and for stroke the length of stroke of the engine in question, the rating revolutions are obtained. Doing this for the 3¼ by 4 engine in question, 1,500 revolutions per minute is obtained, at which speed a 3¼ by 4 four-cylinder engine should give 22½. With a five-inch stroke this would decrease to 1,200 r.p.m.

Without going into pounding too far, it is caused by one of the following troubles: too early spark, cylinder or piston overheated, carbon in the cylinders, uncertain ignition, compression leakage, connecting rods loose, main shaft bearings loose, loose flywheel, or moving parts striking. The latter two can readily be determined, the first is easy to overcome, and the others may be run down one after the other.

As to the chemical theory of burning gases, you will find in the August 5 issue of THE AUTOMOBILE an article on page 226, under the heading "Incomplete Combustion Is Wasteful," which seems to answer all of the questions you have asked.

When it comes to carbureters, you had best write to the manufacturers for their literature and analyze the devices yourself. On page 209 of the issue just mentioned you will find a table of the equipment used on the cars in the Glidden tour, in which will be noted seven or eight makes of carbureters. Taking these as standard, write to their makers for literature, and from this decide for yourself which is best.

The answer to your last question is yes, if you mean special engines, and no, if you mean regular touring cars. By so proportioning valves, ports and passages, together with valve timing, it is possible to produce an engine that simply will not run at low speeds. Such a machine actually would not deliver any power worth mentioning at, say, 600 revolutions, but could be speeded up to 2,800 or even 3,000 revolutions, if desired, in which case it would be developing its maximum power. In the Arrol-Johnson engine, built for the Four-Inch Race, and consequently having a four-inch bore and a very long stroke, the power at 600 was about 12 horsepower. But it was possible to accelerate the speed up to 2,400 revolutions, at which the output was 71 horsepower. Doubtless at higher speeds more power even than this could have been obtained. In a table given for another purpose, on page 606 of the October 29, 1908, issue of THE AUTOMOBILE, the speed of a number of French automobile engines is given. From this we note the following: Sizaire et Naudin, 1,700; Unic, 1,650; Renault, 1,600; Sultan, 1,600; Vinot-Deguingand. 1,500, etc.

These engines were all intended to run at high speeds, and the valve construction, port proportions, pipe sizes, and other influencing points in the design were so laid down as to give this excessive speed. Many of these cars, in fact, are suitable for racing purposes with very slight and immaterial changes, which are confined mostly to the chassis and running gear.

These engines have a pronounced power curve. which rises slowly and continues to rise at the highest speed obtainable.

HOT JACKET INFLUENCE

Editor THE AUTOMOBILE:

[1,977]—I have heard a great deal of discussion of the influence of hot water jackets upon the power and economy of the automobile engine and would ask you to tell me definitely just how this matter of difference in water jacket temperatures can exert any influence upon or change the power of an engine. SAM MANNHEIM.
Albany, N. Y.

In principle, the hotter the jackets the greater should be the efficiency of the fuel, and, therefore, the greater the power and efficiency of the engine. In actual practice, however, the water-cooled engine is limited to a point which will keep the water in the form of water; that is, to a temperature below that at which water boils. This, then, limits the temperature of the water jackets to about 200, or perhaps 205 degrees. The air-cooled engine, on the other hand, is not restricted in any way other than the temperature at which the oil will remain in the form of oil and not burn. This allows any temperature up to about 400 deg. No very complete tests on this interesting subject have ever been made and published, so that we are obliged to refer to those which were made, whether satisfactory or not.

Laying aside all argument on the subject, the test made by S. F. Edge, at London, Eng., with a six-cylinder Napier engine, are good enough to be worth mentioning. In these tests several points stood out very sharply, as, for instance, it was found that the temperature giving the greatest power did not give the lowest fuel consumption, and, of course, vice versa, the fuel consumption did not progress regularly downward with ascending power. Below you will find the series of test arranged in the order of ascending power output:

	Water Jacket Temperature	Brake Horse Power
1	56.0 deg.	6.60 per cent less than highest.
2	115.7 deg.	3.64 per cent less than highest.
3	212.0 deg.	1.00 per cent less than highest.
4	186.0 deg.	0.66 per cent less than highest.
5	149.0 deg.	Highest.

This table shows that, granting the above figures are wholly reliable, the power increase with temperature rise may be plotted as a curve, in which case the above figures show it to have a somewhat parabolic form, with the peak at or just above 149 deg., since at 186 deg. it has already ceased to increase and shows a slight decrease, which, continuing to 212 deg., is nearly doubled.

As stated before, the fuel consumption varies from the power output, this being, in this instance, apparently highest at the same point as before, but none of the other points agreeing. Thus, arranging the results in the order of increasing economy:

	Water Jacket Temperature	Gasoline Consumption
1	56.0 deg.	11.6 per cent more than lowest.
2	115:7 deg.	4.8 per cent more than lowest.
3	186.0 deg.	1.38 per cent more than lowest.
4	212.0 deg.	0.55 per cent more than lowest.
5	149.0 deg.	Lowest.

These figures, too, would seem to admit of plotting as a curve, in which case they would also appear as a parabola with the peak at or just above 149 deg., since again the next higher temperature shows a falling off and the highest shows a greater decrease. The two curves, if plotted, would not agree, as the economy seems to improve more slowly than the power, and falls off much more rapidly, the final figure being nearly 50 per cent. greater, relatively, than in the case of the power curve.

MAGNETO TROUBLE

Editor THE AUTOMOBILE:

[1,978]—Will you please tell me, if you can, what is the trouble with my magneto. I have been having a whole lot of trouble and have finally located it in the magneto. This is a German make and of the low-tension type. The motor is started by means of a battery auxiliary system and runs fine for a short time after starting. When switched over to the magneto it soon begins to miss and slows down, picking up again as soon as the battery is thrown in. The battery was used so much that it became weak, and then I discovered that the engine would run fine on the magneto when run very slowly.
New York City. A. B. BRUSH.

On dismantling the magneto you will find that the casing in which the contact brush is located is full or partly full of oil or water, or possibly both. When the motor is run very fast this is agitated so that it flies all over the interior of the case and soon covers the contact brush and the end of the shaft with which it contacts, so that a short circuit results. Look for a weak spring back of the contact point, too. The trouble will be particularly noticeable if there is a mixture of oil and water in the case, far worse than either one alone. Finding the above to be the case, the remedy is to clean out the case and dry it thoroughly. Then the exact amount of clean, fresh oil recommended by the makers should be put back in. Care must be used at all times in using oil for ignition apparatus, both in the quality and quantity.

AIR PUMP CAPACITY

Editor THE AUTOMOBILE:

[1,979]—Will you please tell me how to figure the capacity of an air pump. I wish to use one but do not know what size to get because I do not know how to figure the capacity. F. L. HUGON.
Alfalfa, Nev.

The usual method of figuring the capacity of air pumps or air compressors is according to the amount of free air which they will pump in a given time, usually a minute or an hour. By free air is meant air at the usual or "free" pressure.

The area of the bore of your pump times the length of the stroke will give the cubic capacity of air drawn in to the cylinder, and if it is assumed that there is no clearance this capacity times the number of revolutions per minute will be the capacity of the pump.

Thus, if your pump was of 3-inch bore by 5-inch stroke, the area of the cylinder would be 7.07 sq. in. This times 5 gives the capacity per stroke as 35.35 cu. in. If, now, the pump is run at 200 revolutions per minute, the capacity per minute will be 7,070 cu. in., or 4.09 cu. ft. per minute, or 245 cu. ft. of free air per hour.

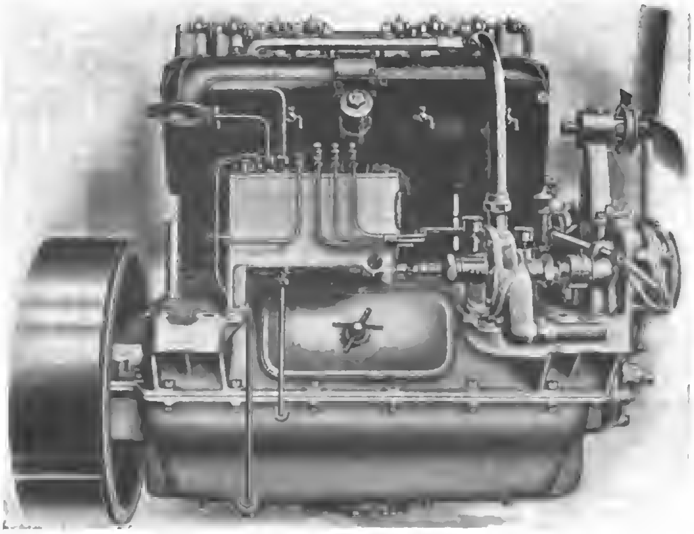
WITH all of the strength and all of the resources afforded by the immense plant at Hartford, Conn., and the greater part of the plant at Westfield, Mass., the rejuvenated Pope Manufacturing Company will endeavor to retain the fame and prestige which has always attached to the name of Pope. The company stands free and clear, the proper officers are in charge, and not a dolllar of indebtedness hangs over them. With wisdom and forethought, it has been decided to concentrate upon a single model which will be built in the conservative number of 1,000 for the season.

This will bear the name of Model T, is a four-cylinder, 40 horsepower car, and may be had, at the purchaser's option, in six different and up-to-date body types. These are: roadster, seating two, three or four as no rumble, single or double rumble is used; pony tonneau, seating four or five; close-coupled body, seating five; seven-passenger, the name of which indicates its seating capacity; and two enclosed bodies, a limousine and a landaulet.

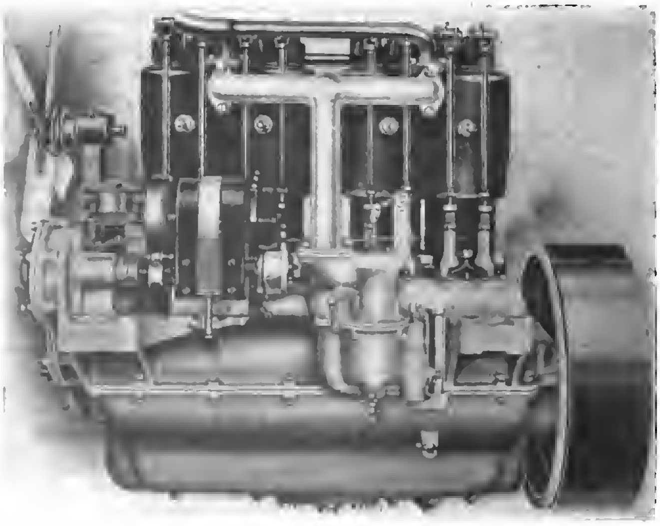
Few Alterations in Design—The changes which have been made since the details of last season's model were announced are few and far between. In the main, they constitute refinements, not changes. Thus, the longer wheelbase allows of a longer, more roomy and, consequently, more comfortable body. The greater length of body calls for slightly different lines, to conform with which the fenders and radiators were altered. The modern tendency to larger wheels is followed, and this year all sizes are 36 inches. The changes which include some actual difference in the design are: the lubricating system; new torque and radius rods; changes in the crankshaft and bearings; new clutch and clutch coupling. Of the latter, however, none of the details are available now.

Doubtless the motor is worthy of the most attention, and this attention will not be wasted, for it possesses many meritorious points. Of the four-cylinder type, with cylinders cast in pairs, heads and water jackets are made integral. The cylinder castings are machined close to size and then ground to an accurate interior surface. Valves are located in the head, in cages which are readily removable and interchangeable. All valves are mechanically operated from the single camshaft on the left side by means of vertical pushrods and overhead levers. The valves are of large diameter, work on a 30-degree taper seat, and are ground to size. The valve springs are enclosed in a neat housing.

Improvements in Lubrication System—Over previous years, the lubrication is much improved; the mechanical oiler has been increased in size, moved slightly forward, an overflow from the oiler back to the oil pocket placed in the bottom of the crankcase, and a suction pump located in the case, which keeps the oiler body full. The oil pocket is cast on the bottom of the case, and is an integral part of it, although separated by a wall. The complete system is such as to lubricate the whole engine very efficiently. Besides the engine, the oiling of other parts is the subject of much consideration. The rear axle is oiled by splash, a large pocket in the bottom of the differential case being filled with oil for this purpose. The transmission is also splash lubricated, a mixture of oil and heavy grease being placed in the case before it is closed. After closing, it is then self-lubricating. All



Exhaust Side of Engine Showing Oiler and Pump



Inlet Side Carries the High Tension Magneto over the car grease and oil cups are freely used, being placed where they are needed or will do the most good.

Clutch Changed and Improved—A clutch of entirely new design is used, this being leather lined, with cork inserts for easy and gradual engagement. It is so located as to be very accessible and thus may be readily adjusted. With this is used a new coupling of entirely new design, which is adjustable for wear.

The three-speed transmission is very compact and is located in the center of the frame, at the rear end of the sub-frame used to support the engine and transmission. The transmission is enclosed in a case, so made that the cover plate is readily removable and is as large as the whole top of the gearbox. To permit of filling the latter with grease or for quick inspection, a circular handhole is placed in the center of the cover plate. It can be opened by turning a single thumb-screw. The gearcase is supported from three points, two in front and one at the rear. At the rear, also, is found the main shaft brake drum. This is of large diameter, of pressed steel, and the brake used on it is an external contracting one, working on the outside.

The transmission gears and shafts are of chrome-nickel steel with the engaging ends of the gear teeth beveled off by an entirely new and different process. Except for the hand levers, the whole gear changing mechanism is completely enclosed.

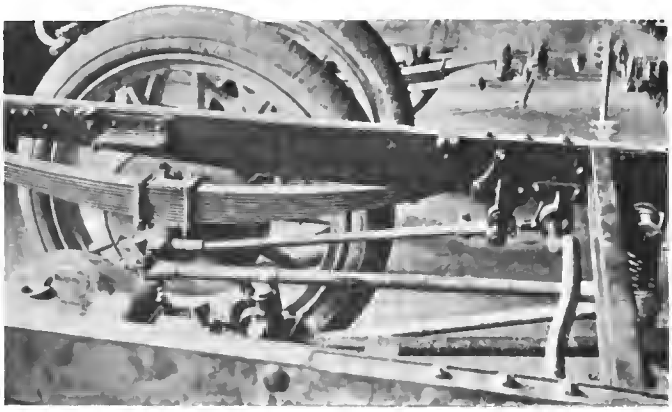
Rear Brake Drum and Brake

I-beam is the section of the front axle, the unit being a solid drop-forging of special steel, made right in the Hartford shops. The drop of the center of the axle bed is very slight, which adds to the road clearance, this usually being the lowest point on the car. Spring seats are forged integral with the axle bed. The axle is of the Elliott type, and the steering arm is below the axle and knuckle. The cross rod, on the other hand, is placed behind the axle, where it is fully protected from road shocks.

Full Floating Rear Axle Details—Clutch type or full floating describes the rear axle, which is made with six integral jaw clutches at the ends. These engage with six corresponding jaws on the outer end of the wheel hubs. The clutches on the shafts and those in the wheels are held into engagement by means of the hub caps, which are locked to the axle. This construction allows of the removal of the shafts with the wheels standing on the ground and without disturbing anything else. The differential is equally easy to remove, when the shafts have been drawn out, and, similarly, no other part need be disturbed.

Both wheels are of 36-inch diameter, fitted with 4-inch tires front and rear. The tires are standard Hartford, but any make will be supplied on special order. The wheels rotate on Timken roller bearings, both front and rear.

Very flat semi-elliptic springs are fitted both front and rear, but there is a difference in the method of hanging them. The front ones are fixed in the front spring hanger, but shackled at the rear, while the rears are shackled at both ends. These are so hung as to be in tension, the rear one from the extended gooseneck and the front from the main frame. This is of armored wood, with a sub-frame of pressed steel. In the construction of the frame the steel strip is placed on the inside, while the wood is outside. This form of frame, a combination of the strength of steel with the springy, flexible qualities of wood, gives to the passenger in the car the best riding qualities obtainable, absorbing the vibrations due to rough roads with facility.



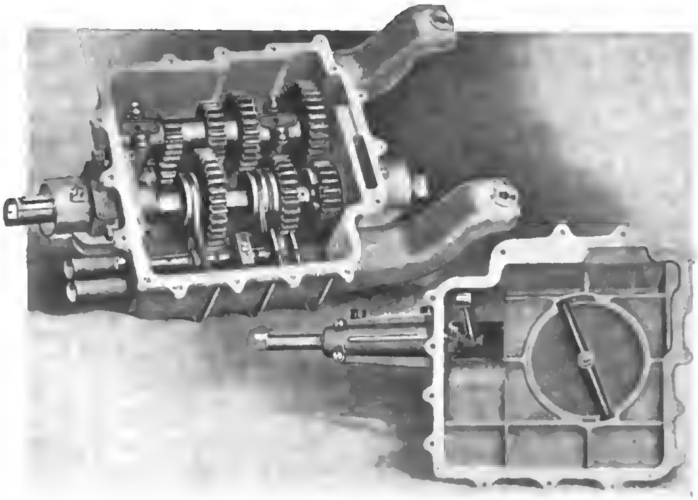
New Radius and Torsion Rods in Place on Chassis

Combined with the very flexible frame, easy riding springs, and the large wheels and tires, the only other thing necessary for practically perfect riding qualities is a long wheelbase, and the new cars have that, too. The wheelbase, which is the same for all bodies, is 118 inches.

Torsion and Radius Rods Relieve Springs—A new style torque rod has been adopted which takes all strain off of the springs. It is of trussed tubular construction, its rear end being pivoted to the rear axle casing, and the front end being fitted with spring buffers, both above and below. These are attached to a special cross member of the frame. The rear end is the double or open end of the triangular form. The rear spring seats swivel on the axle, and the drive is taken by a pair of radius rods, which are attached at the front end by means of an adjustable ball and socket joint to a special bracket located on the main frame. The rear ends of these radius rods are set over the axle tubing loosely so that they may swivel when necessity arises. This is the construction which permits of shackeling the rear springs at both front and rear ends.

There are two complete sets of brakes, the shaft brake previously described and a pair of internal expanding bands on the rear wheels. The latter are of large diameter, work through the hubs, not through the flanges, and are faced with a non-burnable and easily renewable lining. The rear brakes are enclosed. The latter are controlled, or better operated, by the outer of the two hand levers at the driver's right. This operates on a ratchet quadrant, which allows of setting the brake at any desired tension and leaving it there.

Touring car, in standard equipment and finish, lists at $2,750, as do also the roadster, pony tonneau, and close-coupled car. The limousine and landaulet both list at $3,750 alone, but may be had with an additional interchangeable touring body for five at $4,050, and a seven-passenger touring body extra at $4,300. With both of the latter an extra set of rear springs are furnished, as well as an extra set of fenders.



Transmission Displays Gears of Liberal Faces

LATE INFORMATION FOR THOSE WHO TOUR

ROADS BETWEEN SOUTHERN CAPITALS

ATLANTA, GA., Aug. 9—Thirty-odd counties in Georgia, the Carolinas and Virginia are co-operating in the construction of a continuous sand-clay and gravel highway, 750 miles long, linking the capitals and Winter resorts of those States with New York and Washington. When completed this will offer the finest route in the country for Winter touring, as from Richmond southward snow rarely falls. As the surfacing material of the road will not freeze, its condition will be as good in February and March as in the Summer and Fall months.

The route will be known as the "capital highway," because it will connect the State capitals, Richmond, Raleigh, Columbia and Atlanta. From Atlanta there will probably be an extension down to the Florida resorts, and another via Montgomery and Mobile to New Orleans.

At present sixty per cent. of the mileage between Richmond and Atlanta has been improved, and work is steadily progressing on the remainder. The undertaking is being directed by the Capital Highway Association, a body of local men who are interested in the development of the region. Leonard Tufts, of Pinehurst and Boston, is president. Many of the counties using convict labor are claying their roads for $300 a mile. One township in Moore county, N. C., is actually having a section improved by contract at $200 a mile. The contractor does not expect to make any money at that price, but hopes to split even. It is a good road, too, clayed, crowned and ditched. In parts of Virginia the route misses the sand-clay district and runs through a gravel deposit. Dinwiddie and Greensville counties, Va., are paying from $1,000 to $1,700 a mile for gravel roads.

Frank Weldon, secretary of the association, has just returned from a six weeks' pathfinding trip. He says that for the great part of the way the route follows the high land. There will not be a ferry or ford between Philadelphia and Atlanta; every stream will be bridged. At present tourists have the choice of two routes between Atlanta and Augusta, two between Raleigh and Richmond, and three between Richmond and Washington. The State of Maryland is building a macadam road from Washington to Baltimore and one from Baltimore to Elkton. When that is finished it will be adopted as the official route, but meanwhile the best place to cross the Susquehanna is at Havre de Grace, where a bridge will be opened by November. South of Washington good hotel accommodations may be found at many points not over 125 miles apart.

OILED ROADS FAVORED IN BALTIMORE

BALTIMORE, Aug. 9—Oil treatment of roads in Baltimore county has proved quite successful. The people of Green Spring Valley, Roland Park and Park Heights, among whom are many automobilists, are responsible for the introduction in this vicinity of oil for road improvement, and they, together with residents of other sections of the county, will petition the commissioners to use oil on all the heavily traveled roads. Moreover, they express their willingness to bear a portion of the expense. The first experiment was made on the main roadway of Roland Park, with an application of asphaltum; in consequence the roadway has become smooth and hard and all dust has disappeared. On roads where such treatment is not used the surface is continually cut up and requires many repairs.

EDUCATING LOCAL ROADS OFFICIALS

SHAMOKIN, PA., Aug. 9—The recently organized Motor Club of Shamokin held its first run last week, and has as its guests the County Judges and Commissioners and the Roads Commissioners of the seven adjoining townships. The latter afterward met to consider the best way to improve road conditions.

EX-CH'M'N THOMPSON TOURING EUROPE

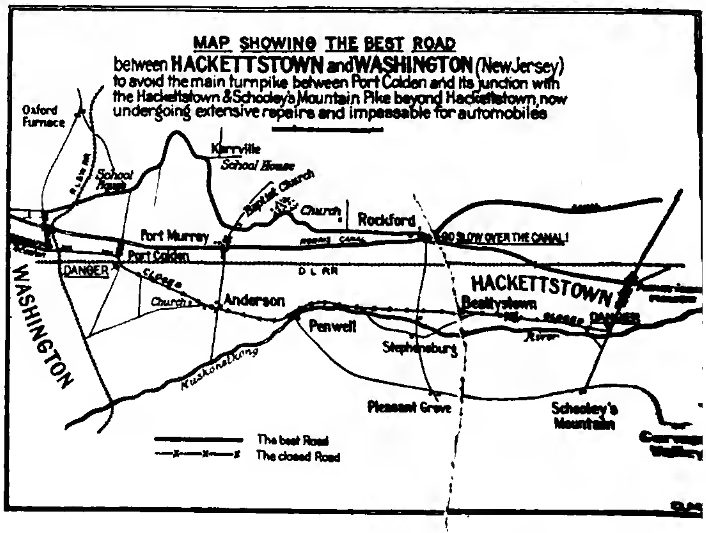
PARIS, Aug. 7—Jefferson deMont Thompson, ex-chairman of the Vanderbilt cup commission and A. A. A. racing board, and Mrs. Thompson recently left Paris in a 65-horsepower Delaunay-Belleville for a tour of Holland and Germany. Mr. Thompson will attend the aeronautic convention at Frankfort-on-the-Main, and later will join Cortlandt Field Bishop, president of the Aero Club of America, at Rheims, for the aeroplane demonstrations at that place.

MICHIGAN CLUBS POSTING SIGNBOARDS

GRAND RAPIDS, MICH., Aug. 9—So much complaint has been made by automobilists in Michigan on account of the lack of signboards on roads throughout the State, that the Michigan association has decided to begin systematically the work of posting all the important cross-roads of the State. The first road to be marked will be the Grand Rapids-Detroit road and the Detroit to Chicago route, via Kalamazoo. To make the work effective it is to be divided among the local clubs. The Grand Rapids club is to take care of the roads from this city to Muskegon, Lansing and other cities. It is expected that many new automobile clubs will be organized in this State during the summer and fall.

TO AVOID AN IMPASSABLE JERSEY ROAD

Owing to extensive repairs, the road from Schooley's Mountain and Hackettstown to Washington, N. J., via Beattystown, Stephensburg, Anderson and Port Colden is impassable for automobiles, and will remain so for several weeks. Tourists going west from German Valley should go to the American House in Hackettstown and turn to the left up Grand avenue, follow that about a mile out of town, then pass under the D. L. & W. R. R. tracks and go straight to Rockport. Cross the canal to the right (go slow); thence straight to the crossroads just beyond to Port Murray Baptist Church—the first church on the right after passing through the woods. Here go straight over the hill to Karrville schoolhouse; pass schoolhouse on the right, and turn to left, following main road—somewhat crooked—three miles. Pass under D. L. & W. R. R. tracks, and turn to the left at first crossroads, into Belvidere avenue, Washington. If going to Easton, Pa., run down Belvidere avenue to Washington avenue; turn to the right, and go straight to Easton, thirteen miles, solid level turnpike road all the way.



Through The ITALIAN LAKES

BY FRANCIS MILTOUN

AUTOMOBILISTS generally enter or leave Italy via the region of the Italian lakes. This is right enough, for without question it is the most romantically disposed of all the varied Italian landscape, and these northern Italian roads are the best in Italy—where they are good; where they are bad (as around Lecco and between Como and Milan) they are as bad as can be, and bad weather makes them worse, so let the automobilist be on his guard.

We had had a delightful run westward from Mestre, opposite Venice, where we had garaged our machine while we did the conventional in the City of The Lagoons. We had made good progress via Padua, Vicenza and Verona, and had dined and slept well at the latter place, at the Albergo Accademia, though there was absolutely no garage, simply an open courtyard in which one might leave his automobile, for which, wonder of wonders, he was charged nothing.

After Verona we skirted the Lake of Garda, through Desenzano and Peschiera, and nearly came to grief while threading our way through its narrow, twisting and half-barricaded streets of the latter place. Peschiera is one of Italy's famous frontier fortresses, where you pass over a drawbridge to get in and another to get out. Most Italian towns have a way around, but here the military authorities have straddled the main road with their great bastions, and travelers in these parts pay the penalty by disaster if they don't watch out.

The Lake of Garda is the largest of the Italian lakes, and to circle it the automobilist will have to pass on to Austrian territory, which is hardly worth while unless one is leaving the country by this gateway. It were better that he should garage his automobile at Desenza and make the lake trip by steamer, over the most translucent blue one could possibly imagine, with a snow-capped mountain background which is delightful.

The Austrian town of Riva at the head of the lake is a more pretentious place than either of the small towns on Italian soil. It possesses a palatial hotel—and some others, and here one finds all the comforts of an exacting twentieth century. Leading to Riva, in case one does make the journey en auto, is one of the best roads of the Austrian Tyrol, the celebrated Ponalstrasse, skirting the eastern shore of the lake. For a matter of seventy-five kilometers this magnificent road shares with the Axenstrasse, near Brunnen, the reputation of being the best in the Tyrol. In case this excursion into Austria is taken arrangements as to custom formalities should be made at Verona, though the Austrian customs house is at Borghetto, forty kilometers away.

The region around the Lake of Garda has one of the most remarkable climates in Europe. The temperature is free from sudden changes, with mild winters and pleasant summers. The midwinter temperature only differs by two degrees, Centigrade, from that of the Riviera, whilst in summer the heat is pleasantly moderate, owing to the south breeze and the shade of the overhanging mountains. The vegetation and flora are identical with those of the Riviera, and palms, camellias and rhododendrons flourish in the open air. No month of the year is devoid of growing flowers.

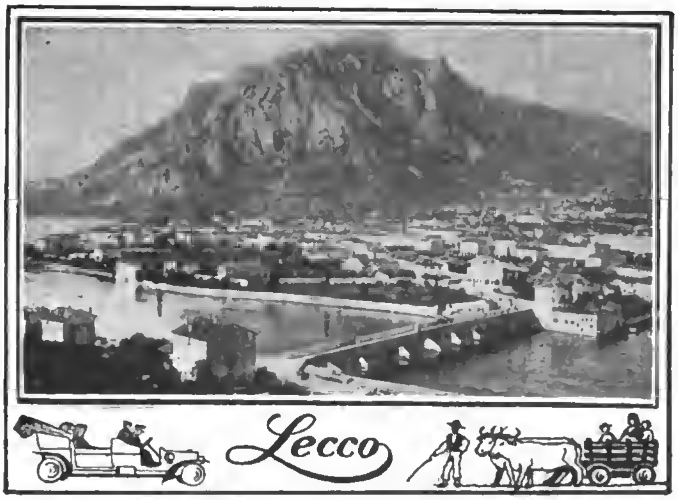
From Desenza to Bresica is thirty kilometers of practically flat and excellent roadway, which continues another twenty kilometers to Coccaglio, and so on to Milan, via Villa Fornaci and Monza, in all ninety kilometers.

From Monza to Milan the Strada Militaire runs parallel with the railway, finally joining up with the Bergamo road and entering Milan by the Porto Orientale. The post road enters the city by the Porto Nuova. For the traveler by road there is no choice between them; they are both "good roads." Roadbuilders in America and England could learn something from the serious contemplation of these two bits of excellent Italian roadway.

All this is encouraging, but if the autoist keeps on from Brescia to Como via Bergamo he sees the other side of the medal. Here is a great trunk line highway, which, a dozen kilometers before Lecco is reached, descends into a slough of the most despicable description.

We had passed the night at the Capello d'Oro at Bergamo and fared, as we had mostly fared in Italy, none too well. We paid relatively high prices for all we got, and two francs more for leaving the automobile in the open courtyard and sheltering a brood of chickens, which otherwise might have got their feet wet. We set out in a hard rain to roll off the sixty-five kilometers between Bergamo and Como as speedily as possible. All went well until within ten kilometers of Lecco. The road then suddenly descended into a slimy mass of mud in six-inch deep ruts. This used up two hours' time exactly. At this rate one would want six months in which to make the Italian tour. Cement and what not, hauled always in the same rut, by great, lumbering, narrow-tired carts is what did the business.

After Lecco we had a climb up from the lake level of a half a dozen kilometers of as fine a boulevard-like roadway as one ever saw. If the rise can be kept in such a good condition surely the descent might be too; somebody had blundered or didn't care—and we suffered.



Lecco

From Lecco, directly north via Chiavenna, runs the international road over the Splugen pass into Switzerland, not open to automobilists unless you happen to catch the officials nodding and rush it. The dogana or customs house is at the twenty-seventh kilometer stone beyond Chiavenna, at an elevation of 1,902 meters.

The descent to the level of Lake Como is dangerously twisting and turning, but fortunately the road improves, and even in wet weather it is firm and wide.

The hotels of Como which care for the automobilist are of all ranks. The Plinius, the Volta and the Suisse rank in the order named. All are of the tourist order, the first named being the hotel de luxe, with a garage for automobile boats as well as land automobiles; give it time and it will probably have a "hangar" for aeroplanes. All are bunched together on the quai just where the boats set out for the upper lake.

Como is a tourist place from every point of view, and visitors are more or less exploited at every turn. The garage charges you a franc more than it ought to for charging your accumulateur, and the wine is strictly non-compris at table d'hote. Still Como is delightful, and is the point de départ for Cernobbio, Bellagic and Cadennabia, at one or the other of which most tourists in these parts stay over a few days and moon about "the perfumed lights from alabaster lamps" in the true fashion of Claude Melnotte and his Pauline. To idle away on the terrace of a villa on Lake Como is to many a more idyllic existance than that to be had beneath a spreading rose tree with a jug of wine, a loaf of bread and—All things to all men! Chacun son gout!

As a stopping-off place for the automobilist en tour Cernobbio, on the Lake of Como, is getting to be the rival of Aix-les-Bains in France. It is what the French themselves would call a *"rendezvous mondain et international."* All the corners of earth are represented on Cernobbio's hotel registers, e'en Stornoway, Esquimault, Brooklyn and Brixton. The Grand Hotel villa d'Est sounds good, is good, and is the rendezvous of the Italian aristocracy in the Spring and Autumn months. Besides being a de luxe hotel of superior attractions it is a historic shrine as well, for the unhappy Queen Caroline, chased in sbame from England's court, once made the villa her home and spent some considerable sums in embellishing it in the early years of the nineteenth century. Napoleon, too, would have made it a place of sojourn during his Italian campaign, and it was actually put in order for his reception, but his plans went awry and he sojourned alone an exile on Elba's Isle instead, his conquest of Europe arrested for the time being.

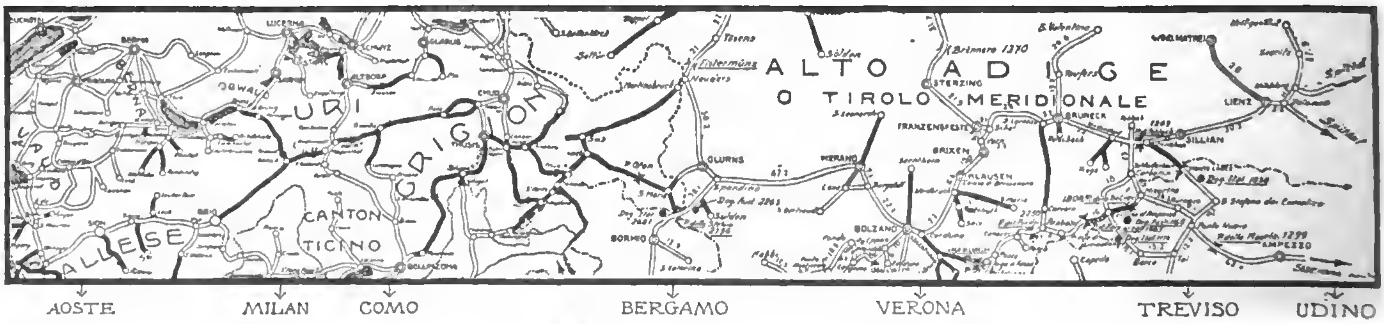
Cadennabia, more than any other place on Lake Como, is mild and sheltered, as is proven by its flora, which blooms continually. Actually in point of climate that of Lake Como resembles that of Touraine. One must make allowances, of course. Sometimes it is delightful at Chinon in Touraine, even in January, and sometimes it is villainous in May. The same is often true of the French Riviera, and the Italian lake region.

To Lugano from Como, and to Bellinzona one passes from Italian to Swiss soil at Chiasso. If one has his Italian-Swiss triptych the passing to and fro is a simple formality, otherwise he had best omit Lugano until he has passed out of Italy for good, via Pallanza, to enter Switzerland by the Simplon Pass.

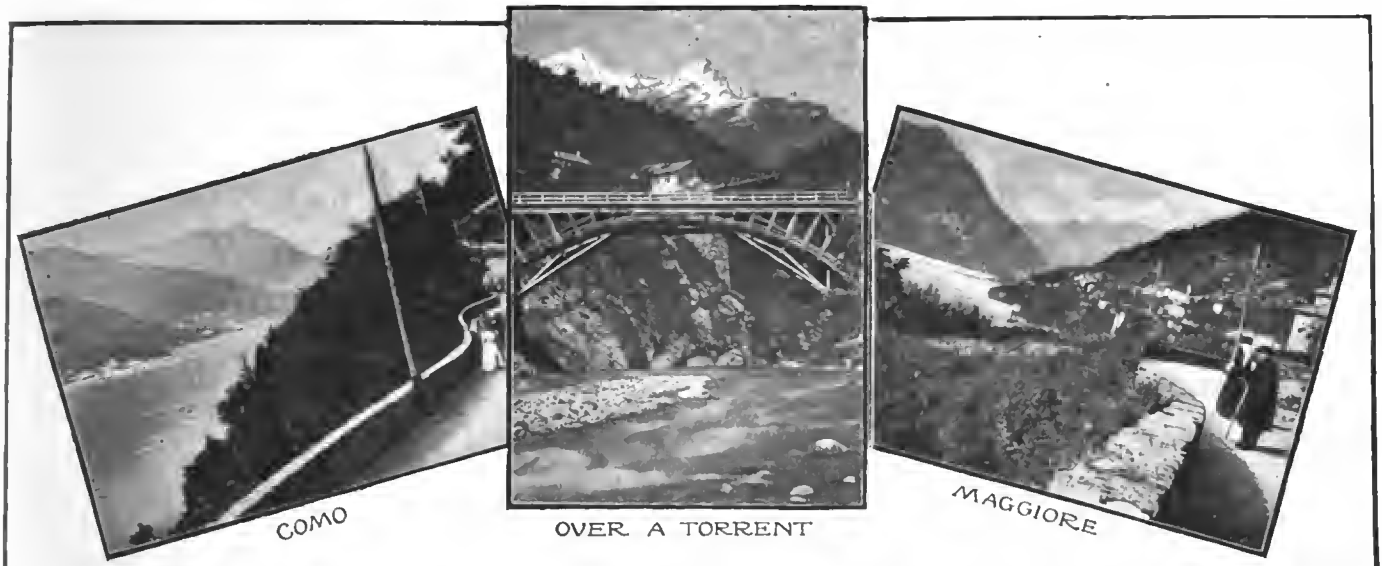
Lugano's Lake has not the charm of Como or Maggiore, but is all around more delightful than any of the Swiss lakes proper. It is in fact a panorama of endless delights, but properly belongs to the Swiss tour, though it groups readily with the Italian lakes in spite of the fact that it lies within Swiss territory.

From Como to Stresa or Pallanza, the centers for Lago di Maggiore, one has to make his way around by a circuitous route via Arona. It took us all of another rainy day to do approximately the hundred kilometers separating the two points, though the roads are of the best. It is indeed true that the road surfaces around Lago di Maggiore are the best in all Italy. They are composed of a cement-like surface, which beds itself perfectly smooth and drains itself readily in wet weather, and does not afterwards break up into a smothering dust. They come very near being the ideal roads of Europe, these roads of Lake Maggiore, but they are not of vast extent, so they do not save Italy from the disapprobation which is justly heaped upon its roads.

Maggiore is the most important, and perhaps the most romantically entrancing, of the world's lakes. One remarks the smooth surface of the waters, the blue sky overhead, magnificent heights bordering the shores, the air fresh but pleasantly comfortable at all but the Midwinter season. One realizes here that he has entered into a new phase of existence, and understands why it is that a more vivid and lasting impression should be made upon him by these Italian lakes than any other similar bodies of water elsewhere. There are higher mountains in Switzerland, and greater lakes in America, but the Italian lakes and mountains captivate us more than all others. People with a certain degree of hardihood have compared lakes and mountains elsewhere with those of Switzerland, but no sane person will venture such a comparison with those of Italy. Without being the grandest or the greatest, they possess indescribable powers of fascination which compel the visitor to admit that they are unequaled, take them all in all.



Italian Austrian & Swiss Mountain Passes
ROADS MARKED in BLACK EXCLUDE AUTOS



COMO OVER A TORRENT MAGGIORE

The Roads of ITALIAN LAKELAND

Surroundings, romantic associations, climate, the colorings of sky, water and mountainside, vegetation, simple churches, the red-roofed houses and the utter absence of smugness are just a few of the reasons which suggest themselves to justify the charm of the Italian lakes.

From Stresa (Hotel d'Italia) or Pallanza (Hotel Metropole) one makes his expected visit to the Borromean Islands. He must do this thing, there would be no reason for coming here otherwise. The magnificent gardens of Isola Bella, the castle of Carlo Borromeo, the Isola dei Pescatori are all classic memories, and one has only to recall Napoleon's stay here as the guest of the Borromean Count, just after he had entered Italy, to realize what an inspiration it was to the ambitious warrior. He dreamed away a night here and set out on the morrow to conquer the Austrians, to push on, if chance favored, to Constantinople, to Moscow, to India or to England. But His march of conquest was never completed as he planned. And what plans they were that Napoleon dreamed that night on Isola Bella!

The automobilist at Stresa or Pallanza, who has come up through Italy, thinks of the morrow, too, ere he goes to sleep for the night, for, unless he proposes leaving Italy via Aoste or Susa and enters Savoie in France, he most likely leaves by way of the famous Simplon Pass.

There are formalities to be fulfilled and they had best be looked out the night before at Pallanza. You may only cross the Simplon between certain daylight hours (eight a. m. to four p. m.) and there are the customs formalities to be gone through at Iselle, where your triptych must be stamped as having left Italian territory, and at Gondo where you enter Swiss control.

At Gravellona, eleven kilometers from Pallanza, one strikes the international highroad which for seventy kilometers climbs up and up to the Ospizio del Sampione at an altitude of 2,008 meters above sea-level. The descent on the Swiss side, to Brieg, is about three times as steep. In twenty kilometers it falls 1,400 meters. Speed is limited officially to twenty kilometers an hour, but the pass has been "rushed" before now to the disaster of many. Look out! or better yet Stop! Look! Listen! at each turning.

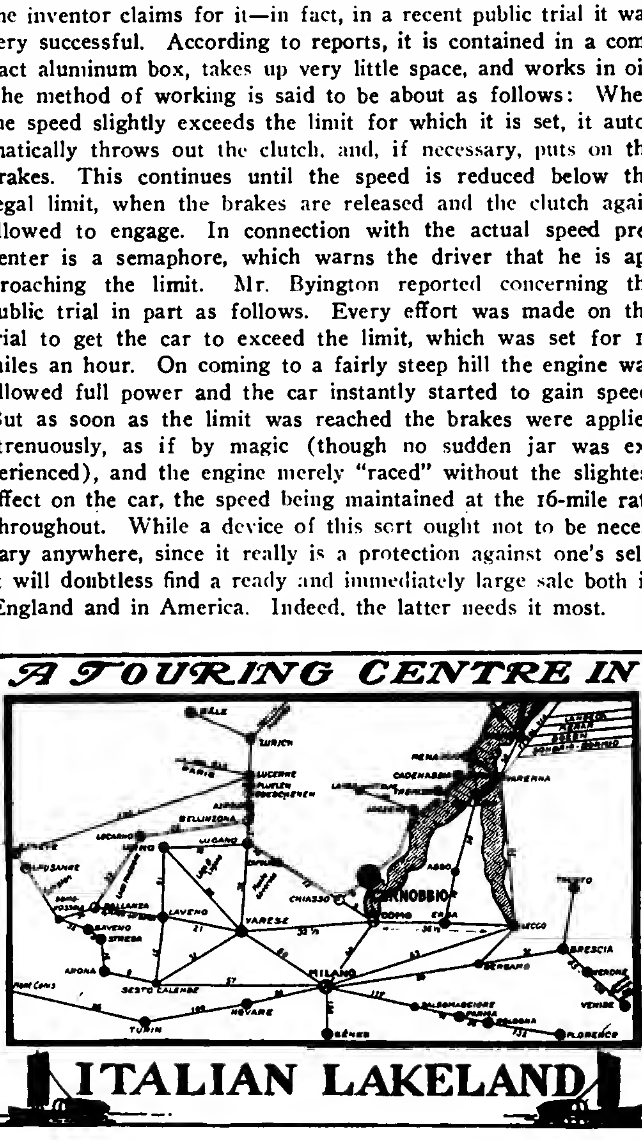
This Simplon gateway to Italy is the most magnificent of all the mountain entrances. *"Domodossola! l'Italie commence ici!"* wrote Edmond de Goncourt as he made his entry by this wonderful mountain road some generations ago.

Domodossola! Good-bye Italy! we say as we turn the prow of our automobile toward the very heart of the snow-capped mountains which mark the boundary between the smiling plains of Lombardy and Piedmont and the stern high valleys of the Bernese Oberland.

INVENTION TO PREVENT SPEED EXCESS

Bristol, Eng., Aug. 3—Through the American vice-consul at Bristol, H. M. Byington, comes a report of a new British invention which is intended to automatically prevent violation of speed laws. Trials have proved that the device will do all that the inventor claims for it—in fact, in a recent public trial it was very successful. According to reports, it is contained in a compact aluminum box, takes up very little space, and works in oil. The method of working is said to be about as follows: When the speed slightly exceeds the limit for which it is set, it automatically throws out the clutch, and, if necessary, puts on the brakes. This continues until the speed is reduced below the legal limit, when the brakes are released and the clutch again allowed to engage. In connection with the actual speed preventer is a semaphore, which warns the driver that he is approaching the limit. Mr. Byington reported concerning the public trial in part as follows. Every effort was made on the trial to get the car to exceed the limit, which was set for 16 miles an hour. On coming to a fairly steep hill the engine was allowed full power and the car instantly started to gain speed. But as soon as the limit was reached the brakes were applied strenuously, as if by magic (though no sudden jar was experienced), and the engine merely "raced" without the slightest effect on the car, the speed being maintained at the 16-mile rate throughout. While a device of this sort ought not to be necessary anywhere, since it really is a protection against one's self, it will doubtless find a ready and immediately large sale both in England and in America. Indeed, the latter needs it most.

A TOURING CENTRE IN



ITALIAN LAKELAND

NEW BOOKS FOR AUTOMOBILISTS

Automobil-Technisches Handbuch—For automobilists who can safely navigate the mazes of technical German this little book offers much interesting information, and will amply repay an hour's labor with a dictionary. It contains good chapters on trigonometry, calculus, statics and mechanics, very useful to the engineer who is a little rusty on these subjects; other chapters treat of the different component parts of the automobile, with examples from current practice illustrated by makers' drawings of the sort that are not often found in print. Then follow detailed descriptions of a number of complete cars, and the fact that these are mostly of French or German origin will not lessen their interest to the designer. Steam and electric cars, motorboats and motorcycles all are included, and there is also a chapter on flying machines. In fact, it is really an encyclopedia of Continental automobile engineering practice. The volume is printed on thin paper and contains nearly 800 pages of fine print. The publisher is M. Krayn, Kurfuerstenstrasse 11, Berlin.

"The Missing Spark"—This is published semi-occasionally by H. L. Humphreys, the automobile editor of the New York *Evening Post*, who tells the "whyfor" of its appearance in these words: "The design of this paper is to diffuse among the toilers in the vineyard a fraternal spirit of good cheer; to inculcate a just appreciation of the great industry, and to cultivate a desire for more business." It would appear from a perusal of the most recent issue that the "Major" has neglected no one who is part and parcel of the metropolitan automobile trade, for all the notables, as well as the lesser lights, obtain some sort of recognition from the versatile Humphreys, whose *Evening Post* automobile department has a patronage commensurate with its high-grade dignity.

"The Sales Booster"—This publication is "issued for the benefit of the live ones who sell the Winton Six," which means that Charles W. Mears, the advertising manager, is more or less responsible for its contents. Of course, the newsy little four-sheeter—it will probably increase in size—contains interesting and timely material concerning the Winton Six and those who assist in its distribution throughout the country, which, according to the "Sales Booster,' 'is done through 11 branch houses and some 99 dealers.

FOR "GOOD ROADS DAYS" AT OHIO FAIRS

Columbus, O., Aug. 9—M. M. Maxwell, secretary of the Ohio Good Roads Federation, is busy arranging for the "Good Roads Day" at the Ohio State Fair, and also for special days at about 60 of the county fairs of the State. The purpose is to work up sentiment among the people in favor of the building of good roads. Tuesday, August 31, has been set aside as the "Good Roads Day" at the State fair. The program for the day will include talks by a number of men prominent in this work, among them Charles H. Hoyt, superintendent of the department of public roads, Washington, D. C. In addition there will be a parade of all road-building apparatus. One of the features will be the building of a stretch of good road to illustrate construction and the necessity of constant care in its maintenance.

Many Steamer-Auto Lines Now Formed—Since the success of the plant outlined last year by the Cunard Company, and recently brought to the attention of tourists on the Continent by the French line, of having automobiles meet their steamers, a number of lines have decided to follow suit. The White Star Company announces that its ships will be met at Queenstown, Plymouth, Cherbourg, or Southampton by reliable touring cars, and drivers, if ordered by wireless. The Cunard Company will continue its method of having cars to run to London or other points from Liverpool.

THE AUTOMOBILE CALENDAR

Shows, Meetings, Etc.

Sept. 21-23.......Cleveland Good Roads Convention, American Automobile Association.
Nov. 6-13........Atlanta, Ga., Auditorium-Armory, National Automobile Show, auspices of National Association of Automobile Manufacturers, Samuel A. Miles and Alfred Reeves, General Managers, 7 East 42d Street, New York City.
Dec. 31-Jan. 7....New York City, Grand Central Palace, Tenth International Automobile Show; American Motor Car Manufacturers' Association, with Importers' Automobile Salon and Motor and Accessory Manufacturers. Alfred Reeves, General Manager, 505 Fifth Avenue, New York.
Jan. 8-15.........New York City, Madison Square Garden, Tenth National Show, Association of Licensed Automobile Manufacturers.
Feb. 5-12........Chicago, Coliseum, Ninth Annual Automobile Show, National Association of Automobile Manufacturers. S. A. Miles, General Manager.
Feb. 22-26.......Kansas City, Mo., Convention Hall, Fourth Annual Automobile Show.

Races, Hill Climbs, Etc.

Aug. 14..........Philadelphia, Point Breeze Track, Hugh McAnany, Manager.
Aug. 17..........Cheyenne, Wyo., Race Meet, Cheyenne Motor Club.
Aug. 19-21.......Indianapolis Motor Speedway, First Race Meet.
Aug. 26-27.......New York City, Brighton Beach, 24-Hour Race, Motor Racing Association.
Aug. 26-28.......Minneapolis, "Little Glidden Tour," Minnesota State Automobile Association.
Sept. 6-11........Lowell, Mass., Automobile Carnival, Lowell Automobile Club.
Sept. 10-11.......Baltimore, 24-Hour Race, Motor Car Racing Association of Maryland.
Sept. 15..........Denver, Col., Start of Flag to Flag Endurance Run to Mexico City.
Sept. 21..........Riverhead, L. I., Long Island Derby, Motor Contest Association.
Sept. 21-29.......Washington-Boston and Return, Munsey Reliability Run.
Oct. 7............Philadelphia, Second Annual Stock Chassis, 200-Mile Race, Fairmount Park, Quaker City M. C.
Oct. 16...........Denver, Col., Start of "Flag to Flag" Reliability Run, G. A. Wahlgreen, Manager.
Nov. 9...........Atlanta, Ga., Track Races, Atlanta Automobile Association.
Dec. 29-30........Philadelphia, Fourth Annual Midwinter Endurance Contest, Quaker City Motor Club.

FOREIGN

Races, Hill Climbs, Etc.

Aug. 22-29.......France, Reims, Aeroplane Races and Grand Prix, Aero Club of France.
Aug. 24-29.......Belgium, Circuit des Ardennes, and Coupe de Liederkerke, Belgium, Automobile Club.
Sept. 5...........France, Mont Ventoux Hill Climb.
Sept. 19..........Austria, Semmering Hill Climb.
Sept. 22..........Austria, Coupe Rochet-Schneider.

AUTO PARADE IN ST. LOUIS CENTENNIAL

St. Louis, Aug. 9—The automobile organizations of St. Louis will co-operate in organizing a parade on October 9, during Centennial Week. There will be divisions for decorated pleasure cars, for those flying the pennant of the A. C. of St. Louis, for commercial vehicles, and for humorous and grotesque decorations. Many prizes will be awarded.

DELAWARE CLUB WILL FIGHT COURT ORDER

Wilmington, Del., Aug. 9—The Levy Court of New Castle County has adopted a resolution offering a reward of $15 to any person causing the arrest and conviction of an automobilist exceedings twenty miles an hour on the county roads. Members of the Delaware Automobile Association will oppose the order, as it opens the way for graft and the depredations of the country constable. The informers may have no means of telling how fast a machine is going, and conviction might result from the judgment of inexperienced persons.

Latest Doings of the Sky Pilots

Their Grandmothers Heard Mother Shipton's Prophecy, and They See the Reality in Bleriot's Flight

CHALONS, FRANCE, Aug. 7—Every true Frenchman is rejoicing in the exploit of Roger Sommer, who to-day wrested from Wilbur Wright the record for duration of flight in an aeroplane. Wright's record, made at Le Mans last December, is 2 hours 20 minutes and 57 seconds. Sommer remained in the air 2 hours 27 minutes and 15 seconds. It is said, however, that his flight will not be regarded as official.

Sommer and Farman, his teacher, have been staying at Mourmelon-le-Grand, a little village on the Chalons moors, secluded from the Parisian crowds. Sommer arose this morning at 2 o'clock and took an automobile out to the shed where his machine was housed. Farman remained in bed. "You will surely break the record," he said, "but I will hear about it in the morning." The moon was still shining brightly when the young aviator started at 3:14.

The machine at first flew low and sluggishly. Afterward Sommer said that as soon as he got in the air he found that the canvas on his lower plane had come loose and was bagging out with air so as to retard his progress. However, he kept on, and in about twenty minutes the propeller in some way struck the bag of air and cut it open. Immediately the aeroplane sprang forward, and the rest of the flight was made at fine speed. Sommer guided his machine round and round in a four-mile circle with the regularity of clockwork at a constant height of about fifteen yards.

When he had been up two hours there was a demonstration by the few spectators who had gathered. Soon he equaled the Wright record, but he made no move to descend until his superiority was beyond dispute. When at last the machine touched the ground at a quarter to six he was seized and carried off the field in triumph, stiff with cold and fatigue, but otherwise none the worse for his exploit.

Sommer is a pupil of Henry Farman, and uses a biplane of the Farman type, which differs from the Wright machine in that it has a box-shaped tail to the rear of the main planes, and but a single lifter-plane in front. He took his seat in an aeroplane for the first time on July 3. Since then he has been flying daily on the Chalons moors, gradually increasing his distance. He first came into prominence July 27, when he made a flight of 1 hour 23 minutes 30 seconds; this at once ranked him among the most prominent aviators. On August 2 he remained in the air 1 hour 50 minutes 30 seconds, and covered nine miles in 12 minutes. August 4, his thirty-second birthday, he celebrated with a flight of 2 hours and 10 seconds. The fact that a man who has been practising for but little over a month can accomplish such flights may well be regarded as a vindication of the practicability of the aeroplane. Sommer no doubt has an especial talent for aviation, and his progress could not be equaled by the average man, but Wilbur Wright was undoubtedly correct when he said that anyone with an automobile training could easily become a successful aviator.

Sommer's Aeroplane Is Wrecked

CHALONS, FRANCE, Aug. 8—Sommer made another short flight to-day in the machine with which he broke the world's record yesterday, but stopped the motor too soon and landed with such abruptness that the machine was smashed. Sommer was unhurt.

ZEPPELIN DIRIGIBLE FLIES TO COLOGNE

COLOGNE, GERMANY, Aug. 5—On its third attempt to reach this city from Frankfort the Zeppelin dirigible was successful, and arrived at 10:15, after having been delayed by unfavorable weather. The big airship left Frankfort at 4:40, cheered by a crowd of 50,000 people. Its progress was reported by telegraph as it sailed down the Rhine. At Limburg, Neuwied, Remagen and Bonn great throngs assembled to watch it. As it approached Cologne, however, it ran into a thick fog and went off its course some ten miles to the southwest. At Dueren it got its bearings again and headed straight for the city. After circling the tower of Cologne cathedral it made a safe landing at Bickendorf, a suburb. The distance between Frankfort and Cologne in a straight line is 110 miles, but the airship covered considerably more than this. Its average speed must have been about 25 miles an hour.

The Zeppelin airship flew from Friedrichshafen to Frankfort on July 31, a distance of 220 miles, with Count Zeppelin himself at the helm. On August 2 it made its first attempt to reach Cologne, but when within 30 miles of its destination was forced back by strong head winds. On August 3 the ship went but a short distance when two of its propeller blades came off.

Count Zeppelin Reported Dead

BERLIN, Aug. 10—It is rumored here that Count Zeppelin is dead, but no confirmation can be obtained. The famous aeronaut went to Constance last week to receive treatment for an abscess.

Military Dirigible Flies Fifteen Hours

BERLIN, Aug. 5—The military dirigible Gross II returned here at 3 o'clock this afternoon after a flight to Halle and return. The distance, 217 miles, was covered in 15 hours and 40 minutes.

CURTISS SAILS TO COMPETE IN EUROPE

Glenn H. Curtiss sailed from New York on the morning of August 5 to compete in the international aviation meet at Rheims, France, August 28. He is the only American entered. His new aeroplane was securely stowed in the hold of the *Savoie*, and with the aviator on deck were his mechanic, Tod Shriver, and Ward Fisher, a friend from Rochester, N. Y. Mr. Curtiss came in from Mineola early in the morning. He had hoped to be able to make a final flight in his old machine, now the property of the Aeronautic Society, and to give a lesson to Charles Willard, who will operate it in the future. The morning was rainy, however, with a stiff northwest breeze, and the attempt had to be given up.

Mr. Curtiss expressed himself optimistically on his chances of winning the big cup race. The conditions are fairly easy, as the circuit to be covered is only 20 kilometers (about 12 1-2 miles); probably half a dozen machines will complete the distance, and the winner will be determined by speed rather than by reliability. For this reason the most dangerous competitors are believed to be the monoplanes. So many entries were received in France that it will be necessary to have an elimination trial to determine the team of three. Entries have also been received from England, Italy and Austria, but none of these will be formidable, judging from past performances. The contest thus seems to be between Curtiss and the three Frenchmen still to be selected.

The aeroplane which Curtiss will use is of the biplane type, 30 feet across the wings and weighing about 400 pounds. It closely resembles the one in which he made his recent flights at Mineola, but will have an eight-cylinder motor of double the power.

Curtiss' Pupil Makes a Good Start

MINEOLA, L. I., Aug. 7—Charles Willard made five short but very encouraging flights this morning on the Curtiss biplane, now the property of the Aeronautic Society. The distances varied from seven-tenths to two miles. On the fourth flight Willard made the first turn he has ever attempted. He also made a flight of a quarter of a mile yesterday morning. Willard, it will be remembered, had his first lesson just before Alexander Williams, who wrecked the machine about two weeks ago. A crowd of 200 persons, among whom was W. K. Vanderbilt, Jr., turned out to witness the trials.

ORVILLE WRIGHT LEAVES FOR GERMANY

Orville Wright and his sister, Miss Katherine Wright, arrived in New York Monday afternoon and left Tuesday morning for Germany on the *Kronprinzessin Cecilie*. Mr. Wright was not accessible to the newspaper men till late in the evening. He was as unwilling as usual to volunteer information, but readily answered all questions. He said that he and his sister would stop off a day or two in England to visit Shell Beach, where a number of aeroplanes are under construction. He does not expect to make any flights there. After fulfilling his business engagements in England he will go to Berlin, and expects to stay there about two months. He will make flights there on the Tempelhoferfeld, under the auspices of the *Lokal Anzeiger*. A company capitalized at $150,000 has been formed in Germany to take over the Wright patents and manufacture aeroplanes. Among its backers are the Krupp Company, the Allgemeine Elektricitaets Gesellschaft and the Ludwig Loewe Company. Mr. Wright would not talk about the possibility of the German government acquiring his patents.

Of more interest to aeronautic enthusiasts in this country will be the news that the Wrights expect to take part in the Hudson-Fulton celebration at New York this fall. Overtures were made to them by W. J. Hammer, vice-president of the Aeronautic Society. The only difficulty is to get ready in time, as the brothers have a number of contracts with time limits to fulfill. Mr. Wright was very optimistic as to the commercial practicability of the aeroplane in the future.

AERONAUTICAL DOINGS IN GENERAL

Experts Define Aeronautical Terms—Dictionaries have not kept pace with the inventors of aeroplanes and the progress of the science, so the international aeronautic congress has taken up the matter of terms relating to aerial navigation. There has been considerable misunderstanding about the use of the words applicable. The congress has decided that "aeronef" is the proper one for heavier than air machines, that "aerostat" is a free or uncontrolled balloon; and that a dirigible, one which can be propelled and has rudders, is an "aeronat." An "aeroplane" consists of surfaces of aero curves with the propeller shafts set horizontally, while a "helicopter" has the propeller shafts set vertically, thus pulling the machine straight up from the ground. "Orthopters" have flapping wings. The navigator of the craft is an "aeronaut," unless licensed by the aero club, when he becomes a "pilot." "Aviator" is the form of the flying machine, not the navigator, and "aviation" is the art of flying. An "aerodrome" is listed as an "aerial track" and in this the congress takes issue with Dr. Bell and Dr. Langley who apply that term to their machines. A "monoplane" has one areo curve, and a "biplane" has two.

Texas Inventor Expects to Rival Wrights—Equipped with an automatic arrangement for balancing, four parachutes for use in case of accident, and built so that it can alight on either water or land, an aeroplane has been built by J. W. Oman, of San Antonia, Tex., with which he expects to rival the Wright brothers. Mr. Oman has included a number of new features in his machine and models have been successful in flight. A company has been formed and full-sized fliers will be constructed this spring. It is claimed that no track is necessary in starting and that only a short run is required, propelled by two 36 horsepower engines, either one of which can drive the aeroplane if necessary.

Bird-like Machine with Magnets Furnishing Power—Victor L. Ochoa, of Arlington, N. J., is working upon a bird-like aeroplane in which propulsion is designed to be secured through the action of aluminum wings. These are operated by large magnets which, the inventor claims, have a power of attracting or repelling two tons. He has been working lately, however, upon a machine of the more conventional type, mounted upon two bicycles, between which is installed a six horsepower engine, and weighing 250 pounds in all. Over a framework canvas is stretched, with a rear rudder similar to the tail of a bird, the total length being 26 feet and width six.

Jupiter, a Horse, Flies in a Balloon—It is more than a press agent description which lends color to the latest performance of the educated horse. In the Barnum & Bailey circus there is a beautiful white Arabian horse, named Jupiter, which is ridden into the ring by a woman, steps upon a basket platform underneath a large balloon, and is slowly raised to the roof of the big arena solely by the inherent power of the gas bag. The picture calls to mind the mythological tales of Germany's war heros. Fireworks are set off to show that the horse is not nervous, but it is not said whether the animal pulls the cord which releases the gas to cause a descent.

Fears Smuggling by Balloons—New problems in aerial navigation are continually arising, and one of the latest is that of the possibility of smuggling across the borders. Chinese and merchandise seem to be the loads generally considered as giving handsome profits. Another question which arose in the minds of some long distance fliers was that of duty, when a balloon or airship arises from the United States or Canada and alights in the other country. Customs officials state, however, that this objection can be easily obviated. If the balloon is made in one of these countries it may be returned to the other after a flight, by simply filling out certain papers.

Aero Club in the Thousand Islands—Dr. J. M. Gibbons, with several other enthusiasts, is organizing an aero club among the members of the various boat clubs in the Thousand Islands. Dr. Gibbons is constructing an aeroplane.

INDIANAPOLIS NEXT WEEK WILL OPEN ITS SPEEDWAY

INDIANAPOLIS, IND., Aug. 9—From a commercial point of view the new Indianapolis Motor Speedway is one of the most daring enterprises ever projected. Ordinarily, when a large amusement production, such as a circus or a ball park, is to be put before the public, it is thought necessary to insure that a great many performances be given in order to bring in any return on the investment. A circus that would perform but fifteen times a year would undoubtedly be a dismal failure. Yet the promoters of the speedway are putting a third of a million into a track, which from its nature cannot be used oftener than once a month, and expect to make the venture a commercial success.

Messrs. Wheeler and Schebler and Their $5,000 Trophy

The cost of the speedway was at first estimated at $350,000, but according to later reports this is being exceeded. One feature that was not included in this reckoning is the laying of a rock-surfaced track. In addition to this outlay, $25,000 will be expended in advertising and promoting the first two meets, and the prizes to be given will total close to $25,000 more. It is evident that the promoters, in making this expenditure, must have counted on an enthusiastic backing by the public, and at present it seems as if they had reason.

The location of the speedway is very convenient. Automobilists may reach it over a well-oiled road, but three miles from the center of the city. The hotel accommodations are ample, and it will not be necessary to drive all night or camp out in the fields. The parking of automobiles will be free, with no extra charge at the gates. For the less fortunate spectators there will be frequent trolley service. The program will begin each day at 12 noon, and will last for six or eight hours.

The opening meet is scheduled for August 19, 20 and 21, and includes altogether 18 events, at distances of from one kilometer to 300 miles. The closing feature of the first day will be the 250-mile race for the $1,500 Prest-O-Lite trophy, open to cars of 301-450 inches piston displacement. The great event of the second day will be a 100-mile race for cars of 231-300 inches displacement, for the $1,000 Motor Speedway trophy. The grand climax will be a 300-mile contest for the $5,000 Wheeler-Schebler trophy, open to cars up to 600 inches displacement. This trophy is over six feet high and weighs 500 pounds troy.

Thirty-four entries have already been received for the various events. The cars named include Stoddard-Dayton, National, Knox, Chalmers-Detroit, Apperson, Marmon, Marion, Lozier, Fiat, Benz and Christie, and the drivers Lytle, Oldfield, Bourque, Denison, Mulford and Hanshue.

During the races the general rules committee of the Manufaturers' Contest Association will meet in Indianapolis to consider the rules for 1910. Practically every manufacturer in the country interested in competition will be represented.

The management has promised that the track will be of a construction that will permit the highest speeds to be attained. The surface will be free from dust and the curves will be of long radius and properly banked. The spectators in the grand stand and in the parking spaces on the inside of the track will have a clear and obstructed view of the course and will be able to follow every movement of the cars. The grand stand will be covered as a protection from the sun, and every convenience will be provided. One of the features will be a timing device built by the Warner Instrument Company, which it is claimed will record the time to the hundredth of a second. A tower 60 feet high will show on three dials, the times of the first three cars in each event. The management believes that the public is interested in clean and fast automobile racing, and will endeavor to supply the kind of sport that will make the enterprise a success.

HOOSIERS FORM ANOTHER AUTO CLUB

PERU, IND., Aug. 9—A number of automobilists and good roads enthusiasts of this city have organized the Miami County Automobile Club. E. Mack Morris is president; Milton Kraus, vice-president; William E. Carson, secretary, and A. H. Kalbfleisch, treasurer. The club will devote particular attention to the promotion of good roads and the enforcement of the laws.

AUTO REPLACES BRONCHO AT CHEYENNE

CHEYENNE, WYO., Aug. 9—The Cheyenne Motor Club will hold a race meet here, August 17, on a four-mile special course, which is just being completed. The track runs around Sloan Lake and is in the shape of a letter D, with only one sharp turn. A grand stand, with a capacity of 7,000, has been erected, from which a view of the entire course may be had. The meet will be under the sanction of the A. A. A. The big event will be a 200-mile race, for which a prize of $750 has been hung up. A 25-mile race will be run as a curtain-raiser.

CONNECTICUT'S LAW NOT YET SIGNED

HARTFORD, CONN., Aug. 9—Speculation is rife as to the probable action of Governor Weeks in regard to the automobile bill now before him. So many rumors have gained foundation to the effect that the bill as passed by the Legislature will be vetoed that some attention has been paid to them. There has been an impression that if the veto is placed upon the act it may be allowed to be forgotten, keeping the present statute in force. This would please the automobilists. Secretary of State Rogers has stated that if the new law goes into effect, setting the date of change of licenses at January 1, those whose licenses expire previous to that time may operate under the old number. New licenses for the Fall will be sold at a pro rata fee.

THE AUTOMOBILE

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

FREE-FOR-ALLS ARE TOO FREE

It is a natural sequence that if competition in race-meets and hill-climbs is to have any value whatever, the contestants must be on as nearly equal footing as possible. 'Tis possible the most useful and enjoyable form of automobile competition at present may be found flourishing in scores of country towns as yet innocent of press-agents and promoters, when the members of the local club come together on the county race-track. No records are broken, save those of the club; no dare-devil drivers dash at death-defying speed; no word of it ever reaches the metropolitan journals. Yet these rural meets provide the best and cleanest kind of sport. They show the relative ability of the different makes of cars represented; they make the owners study their machines and find how to get the best performance from them; and, above all, they interest other people and make the automobile a familiar feature of every-day life.

But it is difficult to keep the sport in this natural and healthy condition. Sooner or later the townsmen grow ambitious; they call in a professional promoter, and hire a barnstorming driver with a three-year-old racing car to attack the mile track record. Perhaps a local celebrity will offer himself as a sacrifice in a match race. For a few days there is great excitement and enthusiasm. But the owners who formerly provided the sport are overshadowed and discouraged, and when the visiting driver leaves, automobile racing in that county has paralysis.

In a slightly different form this often occurs in better known contests. Here the principal contestants may be manufacturers' cars handled by professional drivers, but still stock cars in the usual meaning of the term. Such cars are capable of sufficient speed to excite the crowd, and are sufficiently well matched to provide good sport. But here, too, the special racing car intrudes. It cannot compete in the classified events, but the free-for-all gives it the necessary opportunity. It breaks the record for that particular hill or track, is headlined in the newspaper accounts, and in general is the particular star of the meet.

Of course a free-for-all, theoretically, should be open to everyone desirous of competing; but its proper function is to give a good small car a chance to see if it can beat a car in the next larger class, and get the proper credit if it does so. Perhaps it would be advisable to limit free-for-alls to those who have competed in the classified events. At any rate something should be done to suppress the special racers. If they could be induced to compete among themselves it would not be so bad, but it is noticeable that most of the self-styled "dare-devils" do not care to enter against others of their own class. They prefer to shine in solitary glory.

IN THE SEEKING OF A WINNER

When the general rules committee of the Manufacturers' Contest Association holds its forthcoming session at Indianapolis, it might stop and question if the search for prize-winners in contests is not bringing about a condition of affars detrimental rather than beneficial to those participating. It is a generally understood fact that the prime object of contests is to demonstrate reliability and durability, but not to the extent of unnecessarily blackening a car's running abilities.

Microscopic examination is all very well when it concerns the running qualities of a car, though when it also includes accessories or the manner of their retention it would seem that the search for a winner is leading into byways of small moment in determining the sturdiness and consistency of an automobile. The public naturally wants to have winners evolve in contests, but at the same time there is no demand for carrying the rules to such an infinitesimal point as is being practiced even in events of considerable magnitude. A maximum of regularity can be proven without resort to trivialities that bear the most remote relation to the general excellence of a motor-driven vehicle.

NOW THE TOUR IS THE THING

More people are thoroughly enjoying their annual vacations this year than ever before. The simple explanation is that thousands are becoming intimately acquainted with their own country because of the automobile, which, though it has been stated innumerable times before, is at present giving plenteous proof of the fact that it is the greatest blessing that has been provided for mankind in centuries. Coincident with the abridging of distance, is the healthfulness and enjoyment of the thing itself. A fortnight daily in the open air, through the highways and byways, with kaleidoscopic scene-changing, is a good recipe sufficient for any tired man or woman.

LOWELL NATIONAL RACES TO BE RECORD-BREAKERS

LOWELL, MASS., Aug. 10—More high-class entries made for the Lowell racing carnival indicate the immense amount of interest being taken in the event by the manufacturers of both light and heavy cars. That the National Stock Chassis competition will equal any races run in the East during the past few years, there is no longer any doubt. Of the recent aspirants for laurels in the light-car sweepstakes, are two Stoddard-Daytons and the Rainier car, which scored second place in the recent 24-hour race at Brighton Beach. A new foreigner to enter the same sweepstakes is a 24-horsepower Benz.

That Lowell intends to make a general week of holiday during racing carnival, is evidenced in the plans of the local commercial interests to close down all the mills and factories, as well as smaller places of business, in order that the entire population may turn out and participate in the celebration. At a meeting of the Trades and Labor Council a few days ago, the question of holding the annual Labor Day parade was brought up and it was soon voted against, for it is obvious that Lowell's working men and women will take considerably more interest in a big speed battle than in a procession of toilers.

The novel plan for selling tickets for the races promises to work out most successfully. No less than 20,000 tickets have been turned over to a number of young women in the city, who will do their utmost to sell out. The ten young ladies who dispose of the greatest number of tickets will be rewarded with a delightful trip to Niagara Falls and return.

Entrants in the contest are making arrangements for establishing camps near the course; the first to select quarters being the Knox team. William Bourque of this star team of drivers, visited Lowell a few days ago and negotiated for headquarters on George W. Cummings' place on Dunbar avenue, at the eastern end of the course. A crew of ten men from the Knox factory will soon be in the camp and efforts are being made to give the drivers and mechanics "all the comforts of home" during their stay. Of course Fred J. Wagner is to start the races.

President Heinze, of the Lowell Automobile Club, states that everything is going along swimmingly as far as the road improvement and constructive work on the grand stands and the novel pontoon bridge across the Merrimac river are concerned. More men have been added to the working force of road builders, and Mr. Heinze is positive that the course will be in the finest shape possible, not only for the contests themselves, but also in time for the drivers to try their cars out properly, a week or ten days previously.

THE DEATH OF COLONEL ALBERT A. POPE

COLONEL ALBERT A. POPE, who died at his home in Cohasset, Mass., August 10, was not only a pioneer bicycle builder, but one of the first to become identified with the making of automobiles. Colonel Pope had been in very poor health for several months, so that the end was not unexpected. He was born in Boston, May 20, 1843, and came of a very old family. Serving in the Civil War, beginning as a captain, he rose successively to be lieutenant in the Thirty-first Massachusetts infantry, captain, major and lieutenant-colonel. Following the close of the war, he started the Pope Manufacturing Company in 1877. This firm, presided over by the colonel himself, took up the manufacture of bicycles in 1878. Later, when bicycle manufacturers became numerous, he played a prominent part in the amalgamation of the so-called bicycle trust, of which he became the active head. Beginning in 1897, the Pope-Hartford automobile was built and placed on the market, this being a single and two-cylinder car until 1902, when the first four-cylinder car was brought out. This was followed successively by the annual models up to those for 1910, described in this issue.

In 1898 the manufacture of electrics was commenced in Indianapolis under the name of Pope-Waverly, this business continuing very successful up to the time of its sale last Summer. In 1900 the Toledo plant was started, and in 1901 produced the first car under the name of Pope-Toledo, the name of the company being the Pope-Toledo Motor Car Company. This was retained until very recently, when it was sold to J. N. Willys.

The Pope-Hartford plant, at Hartford, Conn., for the manufacture of automobiles, and the Westfield, Mass., plant, for bicycles, are still in the hands of the Pope Manufacturing Company, recently reorganized, and at present presided over by Col. Albert L. Pope, oldest son of Col. Albert A. Pope. Col. George Pope is treasurer, and Harold L., youngest son of the deceased, was formerly assistant manager of the Toledo plant.

Like most men of capital and business ability, Colonel Pope was connected with at least a dozen corporations and banks as a director or officer. Outside of his business he had many interests, too. He was a member of the Massachusetts Society of the Sons of the Revolution, the Massachusetts Commandery of the Military Order of the Loyal Legion, of the Edward W. Kingsley Post, No. 113, G. A. R.; the Algonquin Club, Boston Athletic Association, Country Club, Art Club, Beacon Society, the Society of the Army of the Potomac, and a life member of the American Academy of Political Science, and of many other trade, social and educational and military organizations

INTEREST IN GOOD ROADS CONVENTION WIDELY EXTENDED

EVERY State in the Union is interested in good roads, and the amount of attention given is steadily increasing. To give each commonwealth an opportunity to benefit by the experience of the others, the national committee of the second annual good roads convention has invited the Governor of every State to send from five to ten delegates to the approaching meeting. Mayors of principal cities have also been asked to send official representatives, so that the discussions in Cleveland, September 21-23, will have an important bearing on the movement.

The committee is pushing its plans rapidly so that all preparations will be completed well in advance. It has been arranged to have President Lewis R. Spears, of the A. A. A., deliver the opening address in the Chamber of Commerce hall; Governor Harmon will welcome the delegates to Ohio, and Mayor Thomas L. Johnson will greet them from the city. The dust problem will be given extended attention, and Provost Hubbard, the chemist in the U. S. Office of Public Roads, will explain some of the difficulties in dealing with the subject. Logan W. Page, director of the government office, is preparing a paper comparing the situation in this country with those of foreign lands, and the farmers' interests are to be presented by Hon. T. C. Laylin, Master of the Ohio State Grange.

Affiliated with the A. A. A. in holding the convention are the National Garage, the U. S. Office of Public Roads, the American Road Makers' Association and the automobile bodies—the A. L. A. M., A. M. C. M. A. and N. A. A. M.

METROPOLITAN TRADE INTEREST CENTERS IN NEW MODELS

NEW YORK, Aug. 9—Automobiledom, locally, is in a state of expectancy during these Summer days, for there is an interval now existing between the completion of the business in the 1909 models and the arrival of the 1910 series. A number of the prominent houses have already received the new cars, some have been delivered, and a few have announced that hereafter the yearly alterations and the classification by the numerals will be discontinued. All along the row, however, from the Cordner Company, just above Times Square to the thriving settlement just above Seventy-second street, and scattered members still further towards Harlem, there is a decided optimism in regard to the business prospects of the season. It makes little difference whether the concerns handle the most expensive big cars, the medium-priced and sized ones, or the very popular small type, the opinions are the same, and branch managers and agency sales managers unite in fearing a shortage rather than an overproduction.

While the new models are en route a number of the agents have moved their quarters so that the changes along the row have been several. The A. Elliott Ranney Company, formerly selling the Elmore, has taken over the new Hudson from Detroit, and has moved to 1928 Broadway. The Hudson cars have been here some time and have been kept busy with demonstrations. The branch of the Speedwell Motor Car Company has moved from its location near Sixty-eighth street to 1657 Broadway. The Simplex Automobile Company has opened quarters at 1862 Broadway, just above Sixty-first street, and the winning car of the recent Brighton 24-hour race has been a center of interest. The Mercer Company has a branch on the corner of Sixty-first and Broadway, with K. H. Slocum as manager.

Of the 1910 cars nearly every concern knows just when the demonstrators will arrive, for the entire season has been advanced by the factories. Carl H. Page & Company has received the first of the new Chalmers-Detroit 30 models, the White Company has a sample of the gasoline touring cars, and the Packard has been on the streets for several weeks. The Harry S. Houpt Company is now looking forward to the arrival of the new Houpt cars in quantities. The first has already been delivered to be used in racing, and the machines for the sales department are well under way. Herreshoffs are leaving the factory at the rate of three a day, but only a few of these are sent to New York. With the new arrangement for selling E-M-F cars along with the Studebakers, the representation for the former will hereafter be handled by the Studebaker branch, and H. J. Koehler has taken the agency for the Hupmobile and Rider-Lewis in place of the E-M-F. The Atlantic Motor Car Company has received the first of the 1910 small Stoddard-Daytons, and demonstrators of the larger models are expected to arrive shortly.

Prospects for the 1910 Haynes as seen from the metropolitan branch are better than ever before, the new model seemingly having made a decided impression upon prospective purchasers. Manager E. W. Headington states that bona fide contracts have been taken through the local office which represent three-quarters of the entire output. The delivery of demonstrators will begin next week. Manager W. W. Burke, of the Mora branch, is awaiting his 1910 demonstrators, and expects to receive them within a few days. The regular deliveries will commence in September, and will give a much better chance than the past season in which the first cars began to arrive in March. Mercer cars are now represented in the local territory by an even half-dozen machines, but a shop order of about 40 machines is about completed at the Trenton factory and deliveries will follow.

Royal Tourists of 1909 have all been sold, and the 1910 cars of two types will soon be on their way. One is a successor of the present big car, with some changes which make it appear lighter, and then there will be a new model with some features that are expected to attract considerable attention. The car will sell for $2,500. Branch Manager Horace B. Hills will have both models as soon as they can be sent from Cleveland. These instances are examples of the condition among all of the agents; a few still have cars to sell and they are experiencing no difficulty in doing this, for it is generally known that changes will be few. Almost every day some newcomer arrives and this will be the order right up to the shows.

BUFFALO SEES RACES ON CANADIAN TRACK

BUFFALO, N. Y., Aug. 7—Old Fort Erie track, across the Niagara river, just in Canada, has been the scene of two days of spirited automobile racing yesterday and to-day. Inasmuch as the promoters were unable to secure a sanction for a meet on a Buffalo track they went abroad. Some stars of the racing firmament were in attendance, with cars of equal renown, and fast time was made in spite of the heavy course and loose sand. Barney Oldfield, Walter Christie, Louis Chevrolet, F. S. Lorimer and Joe Matson were among the pilots, and if they had had a faster circuit they would likely have set some new records.

Lorimer was the only one whom fate seemed inclined to tamper with, for this afternoon in the ninety-sixth mile of the 100-mile Canadian championship he went through the fence in a blinding cloud of dust. So thick was the pall, however, that his mishap was not noticed at first and when the surgeons reached him the autoist was unconscious and found pinned in his car. Serious injuries were at first supposed to have been incurred, but later examination showed only a scalp cut and bruises.

Yesterday was featured by the local appearance of the new 100-horsepower Christie racer, driven by its inventor and builder, and by its breaking of the Canadian track record. The new mark is 54 3-5 seconds. There were five contestants for this honor, their cars and times being: Christie, Christie, 54 3-5 seconds; Oldfield, Benz, 55 2-5; Chevrolet, Buick, 57 3-5; Chevrolet, small Buick, 1:04; Croker, Peerless, 1:07.

The short distance races, at three and five miles, were run in heats, and of the four Christie and Chevrolet each won two. The 50-mile Buffalo derby for stock chassis had two contestants, Lorimer in the Chalmers-Detroit and Chevrolet. The latter won in 52 minutes 10 1-5 seconds.

The program to-day was of much a similar character, with mile exhibition trials, heats at three and ten miles, and the 100-mile Canadian championship. It was in the last of these that Lorimer tore down several yards of heavy fence, while racing with Chevrolet. The Frenchman won in 1:44:32 1-5, a very high rate of speed for a track. One point which caused some gossip and speculation was the fact that Oldfield and Christie alternated their victories, the latter defeating the old Green Dragon man, now in a German car, yesterday, and to-day being himself defeated. It seemed that Oldfield gained time on the curves, while Christie was able to pull away from him on the straight stretches.

In the mile trials to-day Christie reduced his best record of yesterday to 54 seconds flat, and the times of the others were: Oldfield, :55; Chevrolet, :58; Croker, Peerless, 1:00 3-5, and Matson, Chalmers-Detroit 30, 1:06 3-5. In the short races Chevrolet captured two of the four, Christie and Oldfield taking one each. Chevrolet lowered the track record for the 50 miles during the 100-mile event, clipping the best previous time of 51 minutes and 22 seconds to 51:19. The rough course and high speed was hard on tires but no serious occurrences resulted.

HANDSOME ADDITIONS TO NEW YORK'S AUTO ROW

NEW YORK, Aug. 9—Illustrating the trend in the automobile industry towards the refinement of exterior where the interior is already nearly perfect, the factory representatives and dealers throughout the country have of late been giving greater attention to the conditions under which the retail trade progresses. In many cities the old homes of the agencies have been discarded for newer and finer ones, with all modern equipment, enabling the business to be carried on in locations in keeping with the material handled. In no city has this tendency been more marked than in New York, where new structures have been erected, large garages built, and some of the older houses entirely remodeled.

There has been particular activity around the corner of Fifty-seventh street and Broadway, where four concerns have been erecting structures that are solid proofs of the stability of the industry, both in its retail and factory departments. The B. F. Goodrich Company, the Atlantic Motor Car Company, the Peerless Motor Car Company and A. T. Demarest & Company are those which have made this section, just off Columbus Circle, one of the most substantial automobile business blocks of the country. One building 12 stories in height, two with nine floors each, and the fourth with eight, all fire-proof, with exterior and interior finishes that are models, and all for the trade in cars or equipment, form a condition not thought of a few years ago.

A few yards above Fifty-seventh street is the 12-story Goodrich building, constructed of iron, concrete and brick, with the brick used in the walls and front, set off with limestone trimmings and window frames. A particularly pleasing effect has been given to the entrances and the two lower floor fronts by using green marble trimmings, gray marble door frames and gold lettering. The Goodrich Company will use the first floor for its retail salesrooms and offices, the second for additional offices and for factory representatives, and other floors will be utilized for storage space and repair shops. This will leave an immense amount of space to be rented as an investment, and many accessory tradesmen have applied for offices.

The structure to be used by the Atlantic Motor Car Company, the distributor of Stoddard-Dayton cars, is on Fifty-seventh street, just off Broadway, and it is largely connected with the Goodrich building. The same contractors are erecting it, and it really is an L of the larger one, having the steam-heating plant for both in its basement, and the large elevator service is intended to serve both. It also is constructed of iron, concrete and brick, with limestone trimmings, and with its eight floors gives an area of 40,000 square feet. According to present plans the Atlantic Company will occupy the ground and top floors, the Dayton Motor Car Company will have the second, and the rest of the building will be sub-let, with the possible exception of the seventh floor, which the Atlantic Company may require. The second floor has been planned by the Stoddard-Dayton manufacturers as a repository for cars to be shown to the eastern dealers, so that they can see the full line of automobiles in New York as well as at the factory. Each floor will be equipped with a large washstand and other facilities for handling autos.

The Peerless and Demarest buildings have been erected beside each other with a view to harmony in exterior finish, and in keeping with the architecture of a church in the same block, on the Fifty-sixth street corner. They are both fireproof, built of iron and concrete, and the exterior is of white terra cotta. The Demarest Company occupies the corner and the entire building will be used as its factory for making automobile and carriage bodies, principally the former. Considerable space will be used by the general offices, the first floor by salesroom, and a fully equipped automobile repair shop will be maintained. The floor space is 63,000 square feet.

The Peerless branch will be in the middle of the block, also with the entire structure, the different floors being taken up by show rooms, offices, a repair shop, stock room, painting department and two floors for storage purposes. The officers of the branch expect to be fully installed within the month, and will start moving in a few days. This location and equipment will give the Peerless cars one of the finest homes in the country.

The Goodrich Building

Demarest Factory and Salesrooms—The Peerless Branch

Stoddard-Dayton's Home

Four New Buildings Which Indicate Firmness of the Automobile Trade in New York City

Where the Stearns Testers Report to Chief Frank Leland

1,000-lb. Load of Wet Sand Carried in Stearns Car Tests

HOW STEARNS CARS ARE TESTED

CLEVELAND, Aug. 9—The latest idea at the Stearns factory is to have chassis on its road test carry a load of half a ton of sand bags. Mr. Stearns originated the plan himself, believing that the cars should receive rougher treatment at the factory than they could ever be subjected to in an owner's hands. Frank Leland, who is in charge of the chassis testing, established a checking station at a farmhouse sixty miles out of Cleveland, which the testers make the turning point of their daily trips. On the road to and from this station each man is given a certain schedule to maintain, and afterward he gives Leland a full report on the work of his car. These results are carefully tabulated and credited to the chassis number of the car. The load of wet sand carried is more than equivalent to the maximum passenger capacity, for the reason that the sand is absolutely dead weight, and in no way relieves the car in taking the rough country roads and water breaks.

DETROIT TO COAST IN A COMMERCIAL CAR

In order to make an efficient test of the endurance power of the Grabowsky power wagon, and also with the idea of making demonstrations of the car at certain points along the route, the makers, the Grabowsky Power Wagon Company, of Detroit, on Wednesday of last week started one of its trucks westward from the Detroit factory to the Pacific Coast, in charge of J. V. Carr, accompanied by a chauffeur. The idea was originally entertained by entering this car in the Glidden tour, but it was given up on account of the fact that no opportunity would be allowed, during progress of the big event, of stopping at the several important points to display the truck to merchants who are interested in delivering goods by this method of transportation. The progress of the experiment will be awaited with interest by all users and intending users of the commercial car. It is claimed to be the first overland trip to be made by a commercial vehicle for so great a distance—about 3,000 miles.

Grabowsky Car Ready to Start on Its Long Overland Trip

BRETZ'S MAGNETO PREDICTION FOR 1910

"Regarding my recent prediction that the year 1910 will be a magneto year," said J. S. Bretz, of the firm that imports the U. & H. magneto, "I have this to say further concerning it, that even the low-priced cars of the coming year will fit a magneto as part of the regular equipment or as an option. The magneto is no longer a mechanical mystery, and hence many of the makers of this country are, as the great makers abroad have done for some time, fitting a magneto as the sole source of ignition on low-priced cars. It is simply superstition, or rather lack of confidence, that still causes American makers to fit a dual or double system of ignition on any car, and the only reason for their use is for self-starting purposes. As a matter of fact, the added cost and complications are not worth the added convenience. I saw a statement in THE AUTOMOBILE recently that out of a list of 264 American cars sold for over $1,500 in 1909, only 13 of them did not fit a magneto regularly or without an added charge. This is approximately 5 per cent. of the whole. As an evidence of the trend in 1910, I might mention that the $1,750 Inter-State car, an Indiana production which is now being shown in New York, uses the U. & H. magneto as a part of its regular equipment."

GENERAL MOTORS SEEKS RAPID CONTROL

PONTIAC, MICH., Aug. 9—It is probable that within a short time the Rapid Motor Vehicle Company of this city will be controlled by the General Motors Company. Recently when an additional issue of Rapid stock was made, W. C. Durant of the General Motors purchased $200,000 of it. Since then his representatives have been securing options on Rapid stock among its holders, running to November 1.

An addition to the plant has been started, the new building being three stories high, 100 by 640 feet in dimensions, and it is understood that the General Motors will begin another increase, 100 by 300 feet in size. It is expected that the factory will be made the largest commercial vehicle plant in the world. Harry G. Hamilton, the present general manager, will remain in charge.

ARE THERE 40,000 AUTOS IN OHIO?

COLUMBUS, O., Aug. 9—Both Secretary of State Thompson and State Registrar of Automobiles Caley deny the statements recently made by State Highway Commissioner Wonders that only about half the automobiles in Ohio are registered. They point out that the records show that 20,500 licenses have been issued, and if this is but half there must be 40,000 cars in use in the State altogether. This would mean that more than one-fifth of all the automobiles in the United States are owned in Ohio. Clerk McLaughlin of the Department of State also denies the report. In his recent trip over the State looking for violators of the Willis law he failed to see a single untagged car.

MILITARY ASSIGNMENT FOR NEW MITCHELL

Bearing army dispatches, with a definite schedule mapped and the object of visiting a number of government posts, the new Mitchell Ranger, the first of the 1910 Mitchells, will start a transcontinental trip on August 18. New York City to San Francisco will be the route, following much the same one as that taken by the New York to Paris racers two years ago, and the official dispatch will be from Major-General Leonard A. Wood, commanding the Department of the East, to Major-General John F. Weston, commanding the Department of California. The message bearer will also be a soldier, M. E. Parrott of Poughkeepsie, a private in the New York National Guard, and a graduate of a prominent military school.

The car has been completed at the Mitchell factory in Racine, Wis., under the personal supervision of Designer Bate, for it is the first of the new series, and it is stock in every particular. The body will be arranged to carry shelter tents, sleeping outfits and such baggage as may be necessary. Frank X. Zirbes, who drove the Mitchell in the 1908 24-hour race in Milwaukee and in other big contests, will be at the wheel of the transcontinental car all the way.

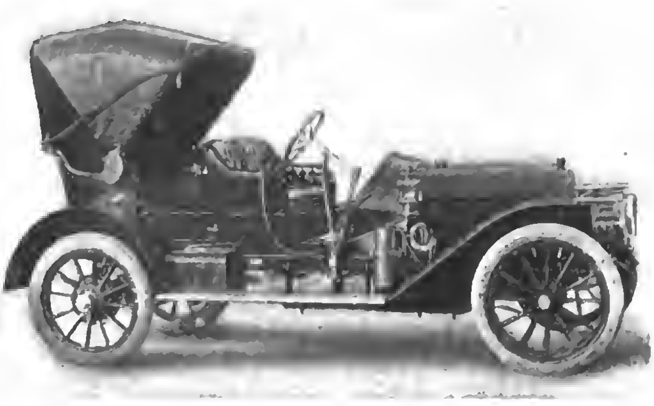
The party will start from Governor's Island in the metropolis and proceed up the Hudson to Albany, then turning westward. It is likely that a number of detours from a direct line will be necessary to reach the military posts.

SEPARATE FACTORY FOR FRANKLIN TRUCKS

SYRACUSE, N. Y., Aug. 9—For the building of commercial cars the H. H. Franklin Manufacturing Company has leased a new building near its present factory. This was done in order to keep the two lines of the business separate, and at the same time to provide space which could not be allotted in the factory a block away. Heretofore the commercial car work has been a part of the general work of the factory. Believing, however, that in the manufacture of trucks there is a rapidly widening field, the company has established this separate commercial car department, with Herbert Hess as manager and W. F. Kneip in charge of the engineering staff. Part of the additional building is made use of by the sales department.

Indianapolis, Ind.—The Meridian Place garage, at Twenty-second and Illinois streets, has just been opened by John S. Lazarus. Roy Lazarus will act as manager.

Utica, N. Y.—Wagoner's new fireproof garage is now open for business at 12 West street. It is an up-to-date building with a capacity for 20 cars.



Secretary of the Navy Meyer's Columbia Victoria

COLUMBIA CAR FOR NEW NAVY HEAD

Among the new and interesting cars just turned out by the Columbia Motor Car Company, Hartford, Conn., formerly the Electric Vehicle Company, none possesses more of interest than the one specially built for the new Secretary of the Navy, General Von L. Meyer, former Postmaster-General. This car, like all other Columbia cars, was built complete in the Hartford shops, even the tops being the company's own design and construction. The top on this particular car is different, just like all Columbia tops are different, in that it partakes of the nature of a victoria top, yet is used on a close-coupled body. The latter, too, was specially made for the Secretary, but the chassis is the regular model, rated at 29-horsepower, cylinders cast in pairs, make and brake ignition, three-speed selective transmission and other regular features. The body is of the four-passenger roadster type, of which the majority of the 500 output for 1910 will consist.

A PIONEER AUTOIST AND HIS CAR

Charles H. Ayars, of Salem, N. J., is one of the pioneer automobilists of that section, and is an active worker in every line in which his fellow enthusiasts are interested. The photograph shows Mr. Ayars and his wife in their new six-cylinder Austin Model 45, with a light touring body. In the background appear Mr. Ayar's home and his private garage. He took part in the automobile parade recently given in honor of Governor Fort of New Jersey when that official visited Salem, and his Austin was considered one of the most attractive cars in the line. Like most of the old timers, Mr. Ayars believes in taking care of the car himself.

Charles H. Ayars, of Salem, N. J., and His 45-Horsepower Austin Tourabout

A Garage of Picturesque Architecture at Troy, Ala.

The rapid development of the automobile business in the South has resulted in the rapid multiplication of garages. The picture was taken upon a recent delivery of Rambler cars at this point, the proprietor, Mr. Henderson, being the Rambler representative for that territory.

Lebanon, Pa.—The Lebanon Automobile and Garage Company, on Sixth street, just north of Cumberland, has opened its new building. This is 100 feet long and 27 wide, two stories in height, and constructed of brick. It has been made to accommodate 19 automobiles on the first floor, and 15 on the second, access to which is secured by a large electric elevator. There is a separate one-story building adjoining for the offices. One feature of the garage is the front, in which there are 10 big sliding doors, each wide enough to admit a car. As a part of the opening celebration a short run to Cornwall was made, in which 28 machines took part—21 were Fords, four Buicks, one Oldsmobile, one Chalmers-Detroit, and one Oakland. The proprietors of the establishment are John F. Allwein and Henry H. Hersberger.

San Antonio, Tex.—Increasing numbers of automobiles have made necessary the construction of additional garages, and through the efforts of the Publicity League it is understood that two will be erected within a short time. One will be located at the corner of Houston and Nacogdoches streets, one story high, of brick and concrete, with 5,000 square feet of floor space, and it will be modern in every respect. The owners are T. L. Conroy, H. B. Rice, and James Byrne. The second garage and salesroom will be built on East Houston street, between the post-office and Nacogdoches street, and it also will be constructed of brick and concrete, one story high, with 5,000 square feet of space.

Pensacola, Fla.—A company has been formed and will be incorporated to construct one of the finest garages in the South at 30 East Garden street. The building will be 60 by 190 feet in size, three stories high, and fireproof throughout, using only concrete, brick, and steel in its construction. It will be fully equipped with necessary machinery for repairing automobiles, and for repairing and vulcanizing tires. The business will be under the control of William Bloomfield, and the mechanical departments will be directed by L. F. Musach. The incorporators of the concern are: Whiting Hyer, William Bloomfield, Henry Hyer, George Turner, Felo Turner, Roy Packard, Hal Packard, James Leonard.

Waterloo, Ia.—The Corn Belt Auto Garage is making plans for erecting a new building at the corner of Water and Fifth streets. It will be one story high, except the main-office part, which will have two. On Fifth street the building will be 50 by 150 feet in size, and on Water street the dimensions will be 40 by 90 feet, for the ground secured is in the shape of an L. The Fifth street side will be used for displaying the cars handled, and the wing will be given over to the mechanical and storage departments. There will be 11,000 square feet of floor space in all.

Denver, Col.—Automobile Row in the Mile-High city has received a push in a new direction, away from its present confines on Broadway, between Sixteenth and Seventeenth avenues. George E. Hannan has purchased ground on Broadway near Twelfth avenue and a large garage will be started there at once, the plans calling for a building of two stories height, with offices on the second floor. The Fernald Automobile Company has also bought two lots between Eleventh and Twelfth avenues and will build in the near future. It is understood that two other firms are figuring on locations in the same vicinity.

Aberdeen, S. D.—The Motor Inn, the new garage of the Heaney Automobile Company is now completed. It is located on Lincoln street, just south of the Gottshalk theater, and is one of the finest structures in the city. It is 100 feet long and 50 wide, with walls of pressed and plain brick, floors of concrete, and large doors and windows. A handsome salesroom, completely equipped machine shop, and large garage are included in the establishment. The company has the agency for the Brush and Waverly, and is the distributor for Minnesota, North and South Dakota, of Halladay cars.

Carthage, Mo.—The garage firm of Bryant & Caffee, occupying the Gilmore building on West Fourth street, has secured 25 feet additional ground east of their quarters and will use it to enlarge the structure. The ground floor will be increased in size by that much and a second floor will be built over the entire place. When the alterations are completed the firm will have a total floor space of 150,000 square feet. A heavy-duty electric elevator will be installed. The agency for the Hudson has been added to that for the Chalmers-Detroit and Reo.

Detroit, Mich.—The Anderson Carriage Company has erected a 60 by 120 garage of brick and concrete construction, with a tile roof supported by a steel truss frame, to be used exclusively for the care and storage of electric cars. The location, on E. Grand boulevard, north of Jefferson avenue, is convenient for the great number of electric vehicles in use on the east side of the city. The garage is attractive in appearance, being somewhat of the Mission style of architecture.

Winchester, Va.—In order to stimulate touring through the Shenandoah valley region, and in the interest of better roads, the Shenandoah Valley Garage is offering free storage to all tourists. Under the management of N. A. Cooper, this establishment, located at the corner of Market and Piccadilly streets, is desirous of having the autoists of the large cities make the run through the famous section of the state, and gives the storage with its compliments.

Albany, N. Y.—Architects are at present engaged in preparing plans for the erection of a new establishment for J. A. P. Ketchum of Saratoga Springs, the agent in this part of the state for Packard automobiles, Mr. Ketchum has a large garage in Saratoga Springs and the one here will be equally as complete. It will include salesroom, repair department, and storage space for a large number of machines.

Louisville, Ky.—Plans have been made for the erection of an immense garage for the Brick Motor Works in this city. The building will be three stories high, and its dimensions will be 52 by 200 feet.

Long Beach, L. I.—A garage is in course of construction on Long Beach boulevard, just opposite the Old Inn. The building is 100 by 80 feet, and will be open for business by August 1.

St. Joseph, Mo.—The Eads brothers have moved into their new garage at Seventeenth street and Frederick avenue, where they have the agency for the Mitchell.

Cincinnati, O.—The Cincinnati Automobile Company is having a two-story addition built to its quarters on Race street between Ninth and Court streets.

Told in the Progress of the Industry

The Observations of an American—Among the recent homecomers over the Atlantic highway was "Jack" L. Straub, a member of the J. S. Bretz Company, who has been for the last three months in Europe in the interest of his concern. Mr. Straub said that while the automobile business in Germany was good and prosperous, production there was limited and that the German makers would not produce over 15,000 automobiles during 1910, which is a very small number indeed when compared to the estimated number of from 150,000 to 200,000 that would be produced in this country. He also saw the start and finish of the Prince Henry tour in Berlin and in Munich, and was impressed with the German method and results in conducting the tour, and thinks we might well appropriate some of their ideas. Mr. Straub says he saw Count Zeppelin in his dirigible in one of his flights, and that it was a wondrous spectacle; the thing appeared as big as an ocean steamer to the ordinary observer.

Diamond Analyzes Tire Cost—The Diamond Rubber Company has published a statement of the cost of tires in the recent Glidden tour, showing the cost of traveling over the rocky and gully-scarred trails which the tourists often encountered. It would seem that the automobile owner had better pay cheerfully his share of the cost of good roads and save on tire expenses. According to this analysis, the average tire cost per car, on all the machines in the run, was $32.50. The Diamond Company says, however, that the average expense of the cars using Diamond tires was but $26.84.

Driver Accidentally Killed—John Swanson, the head tester of the Pope Manufacturing Company, Hartford, Conn., was accidentally killed on July 26 at Windsor, Conn., when out riding in a car belonging to a resident of Hartford, and driven by a fellow worker. Swanson, who was sitting in the tonneau was thrown out when the car rounded a curve too fast and collided with a telegraph pole. The young lady who was with him fortunately was not injured.

Factory for New Maxwell Model—The Cranston, R. I., plant of the Maxwell-Briscoe Motor Company will soon be ready for manufacturing operations. In accordance with the policy of the company, this factory will be devoted exclusively to the manufacture of one model, the new $850 four-cylinder runabout. The Newcastle, Ind., plant will make the $550 runabouts and the factory at Tarrytown will manufacture the big four-cylinder cars.

Colvin-Prost Tire Protector—The Colvin-Prost Mfg. Co., has been organized in Lansing, Mich., for the manufacture of a new metal tire protector. The members of the company are F. R. and C. R. Colvin and C. A. Prost. The protector, which is the invention of F. R. Colvin, is made entirely of steel, fitting over the tire nearly to the rim, but without interfering with its resiliency.

Muncie Concern to Make Auto Castings—The Muncie Foundry & Machine Company, of Muncie, Ind., has been equipped to specialize in the manufacture of automobile castings. A. C. Lipsitz, formerly of the Michigan Motor Castings Company, of Flint, will be the manager, and Edwin C. Slatery, formerly of the Michigan concern also, will be the superintendent.

Westinghouse to Make Motors—It is reported that the Westinghouse Machine Company, of Pittsburgh, Pa., is to take up the manufacture of automobile motors, in addition to electrical machinery. The company has been experimenting for some time in this direction, and had made all the necessary preparations be-before it accepted the order for 1,000 motors.

Hearst Prefers the Matheson—William Randolph Hearst recently cabled his New York office from Italy to ship his Matheson car to him at once. Mr. Hearst had this same car abroad with him in the Summers of 1907 and 1908. This year he started with another car, which is reported to have broken down. Hence the hurry call for his old standby.

Timken Enlarges Plant—The Timken Roller Bearing Company is making additions which will practically double its plant at Canton, O. The officers of the company are very proud of the fact that the cars which won all three trophies in the recent A. A. A. Reliability Tour used Timken bearings.

Defiance to the Automobile Industry—The automobile industry of northwestern Ohio is to be augmented by the Defiance Screw Machine Products Company, which has just been incorporated and has started the erection of a factory at Defiance, Ohio. Metal automobile parts are to be made.

The White Line Radiator—The F. B. Stearns Company has applied for a copyright on the use of a white line around the radiator, as on the Stearns cars, in order to protect themselves in the rights to their slogan "The white line radiator belongs to the Stearns."

IN AND ABOUT THE AGENCIES

New Franklin Branches—The Franklin Automobile Company, the selling company for the H. H. Franklin Manufacturing Company, has added six branches to its list of those in New York, Chicago, and Boston. The half dozen new ones are in San Francisco, Pittsburg. Buffalo, Rochester, Syracuse, and Albany. The managers of the new branches are, respectively: John F. McLain, W. F. Reynolds, George Ostendorf, F. H. Sanders and George E. Messer, with the appointment for Albany to be announced. Each of the appointees has been a district representative for the Franklin Company. In connection with these selections is announced the appointment of T. R. Lippard as assistant general manager of the Franklin Automobile Company. Mr. Lippard has for the past two years been connected with the executive office of the manufacturing company. The managers of the three Franklin branches heretofore maintained are retained for 1910 as follows: New York, W. S. Jewell; Boston, A. B. Henley; Chicago, F. L. Thomas.

Franklin, New York—A building having five stories and basement, on Eightieth street just west of Broadway, has been leased for a repair shop by the New York branch of the Franklin

Annual Outing of the Young Women Employees of the Franklin Factory—The Start at Burnet Park, Syracuse, N. Y.

A Type of the Lights that Are Required by the Recently Enacted French Lighting Law

According to the new automobile regulations which require that the number should be as bright at night as in the day, some form of luminous number is necessary. Above is shown three views of one form of tail number now in use. An electric light with the aid of numerous reflectors illuminates the whole surface of a plaque upon which the number is placed.

Automobile Company, larger quarters than those it had had in use being required for its purposes. The building has a frontage of thirty feet and a depth of 100 feet. The headquarters of the branch are at Broadway, Amsterdam avenue and Seventy-third street.

Packard, Hartford, Conn.—The Packard distributors have secured the third floor of the R. D. & C. O. Britton building, where headquarters for this section will be established. The Packard does not conflict with the cars handled by the Britton Brothers. M. J. Budlong, of the Packard Motor Car Company, has been in Hartford to bring the deal to a close. Charles Embilton, of New York, will be the sales manager of the new concern.

Maxwell, Boston—Frank J. Tyler, manager of the Maxwell-Briscoe Boston Company, announces the purchase of the Kenney & Clark stable property at the corner of Massachusetts avenue and Newbury street. The building is a modern one and will need but slight alterations to make it suitable for the automobile business. A large garage will be conducted.

American Simplex, Boston — The American Simplex Company has moved its Boston headquarters from 10 Columbus avenue to a more commodious location at 261 Dartmouth street. Manager Turner has engaged Walter C. Cady, formerly with the Boston Packard agency, to increase his selling staff.

Rider-Lewis and Hupmobile, New York City—The H. J. Koehler Company, Newark, N. J., has secured a large slice of eastern territory for the Rider-Lewis and Hupmobile, and will also make a car of its own.

Goodrich, Boston—The Goodrich Tire & Rubber Company is erecting a five-story building at 853 Boylston street for the use of its branch. The structure has been promised for occupancy on October first.

Haynes, Brooklyn, N. Y.—Joseph D. Rourk, 1001 and 1003 Bedford avenue, has taken the agency for the Haynes cars, and will be the sole representative in Brooklyn and Long Island.

Oldsmobile, San Francisco—The Oldsmobile agency in this city has been transferred to the Howard Automobile Company, managed by Charles S. Howard which also handles the Buick.

Rambler, Brimingham, Ala.—J. E. Henderson, the Alabama state agent for the Rambler, and Nat Granger, from the Thos. B. Jeffery Company, are arranging to open an agency here.

Mitchell, Atlanta, Ga.—The Mitchell will be represented here by R. C. Howard, who has secured the agency for a large part of the state. He will be located at 88 Prior street.

Chalmers-Detroit, Wilmington, Del.—Col. Grantley P. Postles has taken the Chalmers-Detroit agency and is now settled in the Dupont Building on Market street.

Hudson, San Francisco—The Pioneer Automobile Company, which holds the agency for the Chalmers-Detroit, will also represent the Hudson roadster.

Hupmobile, Louisville, Ky.—The Hupmobile will be handled in this city by Fulton Mandeville, who will open salesrooms as soon as possible.

Chalmers-Detroit, New Bedford, Mass.—Wayland L. Sturtevant has taken the agencies for the Chalmers-Detroit and the Hudson roadster.

Pennsylvania, Ford, Hupmobile; San Antonio, Tex.—The Lemly-Mills Auto Company, corner East Houston and Nacogdoches streets.

PERSONAL TRADE MENTION

George S. Waite, of Boston, has accepted a position as general sales manager of the American Simplex Company and will be located at the home office. Mr. Waite has resigned as sales manager of the Boston Packard agency to take up his new office.

Charles W. Talbot has taken a position as salesman and demonstrator with Ellerd Brothers, the Franklin agents at Plainview, Tex. Mr. Talbot has been with the H. H. Franklin Company for a number of years as a contest driver and demonstrator.

Frank Bowen, for many years connected with the Ford Company, and later with the Houpt Company, has become a member of the Carl H. Page organization, and from August 1 will be identified with the Chalmers-Detroit.

A. L. Bolster, for ten years connected with the Fisk Rubber Company, has been appointed Philadelphia manager for that company, with headquarters at 258 North Broad street.

RECENT BUSINESS CHANGES

Etablissements Lemoine—This well-known French company, a maker of springs, axles, forgings, etc., for automobiles, will henceforth be represented in the United States by the International Engineering Company 1779 Broadway, New York City, instead of by Lavalette & Company, as formerly.

The Ewing Auto-Cab Company, it is said on the authority of a stockholder, has decided to move its factory from Geneva, Ohio, to Easton, Pa., but the removal will not take place for some time, as a suitable building must first be erected in the latter city.

TAXICABS AND TRANSIT

Bellefontaine, O.—A number of local capitalists are interested in a project to establish an auto omnibus line between this town and Richwood, O., and have interested the Commercial Club in the project. The country is thickly populated and not served by any electric line.

TO MAKE TRUCKS IN MINNEAPOLIS

MINNEAPOLIS, MINN., Aug. 9—A company to be known as the Minneapolis Motor & Truck Company has been organized here with a capital of $500,000 to manufacture touring cars and trucks. Land has been purchased for a factory and work will be started as soon as possible on a large concrete building. The motors to be used are of the two-cycle, three-cylinder type; drive will be by shaft except on the heavy trucks. One light truck will be interchangeable with a touring car body, and will be known as the "Handy Man." This is intended to appeal especially to farmers. The one chassis will take several different bodies and will be strong enough to carry a load of one ton. By an ingenious arrangement the rear wheels can be jacked up and a belt adjusted to guides on the spokes; the motor will then be useful in many ways.

Some Recent Trade Publications

Oscar Lear Automobile Company, Springfield, O.—Catalogue of Frayer-Miller blower cooled motor trucks, and facsimile letters commending the same. Since the letters come mostly from hilly country, or, rather, from cities which are known to be very hilly, the letters are more convincing than such letters usually are. Among the well-known cities included are Pittsburg, Cincinnati, Denver, Troy, and Chicago, the latter, while not so uneven as the others, being equally well known as hard on horses and trucks. Three forms of commercial vehicle chassis are made by this concern, these being the delivery wagon, 1 1-2-ton truck, and the 3-ton truck. They are each fitted with a number of bodies, which allow of their adaptation for numerous and varied uses. Much space is devoted to the blower cooling proposition, original with this firm, and very lately adopted by another prominent air-cooling advocate. Beyond this are a number of new and excellent pictures of three-ton trucks, with widely different bodies. They include the standard stake truck, long stake, stake and bar combination, express, enclosed, sight-seeing, bus, and many special large capacity bodies. Since businesses requiring a motor truck, particularly those necessitating as large a truck as a three-ton vehicle, need different body types, those shown are of great interest.

Packard Motor Car Company, Detroit—As the title of this small folder, "Packard Three-Ton Trucks in a dozen different lines of business," would seem to indicate, it is devoted to a display of three-ton trucks at work in many different fields of endeavor. Since actual photographs of cars at work are far more convincing to the average man than any amount of talk or catalogue language, this little book will do much useful work. Doubtless the most convincing of this lot of persuasive pictures is that of the vehicle now in the service of T. G. Patterson, Inc., New York City, which is built with a very strong, overhanging body so as to accommodate large bulky loads. When running in the streets of the big city with its enormous loads, it is always an object of much interest. Next to this, the record of the sales made to the Adams Express Company, New York City, will be very convincing, as it shows that, following the first trial order in September, 1905, this company has bought Packard trucks continuously, in August, 1908, October, 1908, and in June, 1909. This would not have been the case had the trucks not "made good," so the three repeat orders speak volumes for the merit of Packard trucks.

Geiszler Brothers, New York City—Besides a book describing the Geiszler storage battery in detail, this firm is sending out a pamphlet entitled "Are Geiszler Storage Batteries Non-Sulphating?" consisting of a series of questions and answers relative to sulphation. These questions take up in the most pointed fashion the subject of sulphation, its cause and remedy. Although a small leaflet, this should be in the hands of every battery user, for the information which it contains. The book goes into the construction of batteries in a very plain, sensible way, telling first what a storage battery is and what it is for. The active material is then described and its formation and diseases mentioned. The Geiszler battery is made with an extra thick rubber case, divided into compartments, within which the plates form separate batteries. Each one of these compartments is sealed on the outside by means of a hard rubber cover, which is the internal one, and an outer sealing compound. This makes the whole both acid- and water-proof, which is an appreciable advantage.

Apple Electric Company, Dayton, O.—Intense and widespread interest in the subject of improved lighting for automobiles just at this time makes the appearance of this folder entitled "Electric Lighting System for Automobiles," particularly appropriate. The system described and illustrated is, of course, the Aplco system, in which a special dynamo is used in connection with a 6 volt 100 ampere hour storage battery. The very even and regular current output, regardless of the speed of the engine, so necessary for success in electric lighting, is secured by the use of a recently perfected and patented device which is called a load regulator. This device holds the current output down to very close limits, and through the medium of the cut-out switch, does it in such a manner that none of the generated current is wasted. Aside from a description of the system and its cost, a very convincing set of pictures show how the system may be applied to a number of popular makes of car, a Franklin, Stoddard-Dayton, Cadillac, and others being shown.

J. H. Williams & Company, Brooklyn, N. Y.—Drop-forged wrenches of the "Vulcan" brand, illustrated and thoroughly described, comprise the main portion of an artistic catalogue of most convenient size issued by Williams & Company. From five-inch down to the diminutive one-eighth inch, the sizes are shown in single or double head, straight or S shape, and for a large variety of purposes. A novelty in triple-head wrenches is shown and also thin wrenches for use on lock nuts. In addition, a variety of general forgings such as lathe dogs, hooks, machine handles, tool posts, etc., are illustrated for service in the shop. For the experimenter or manufacturer are crankshafts, connecting rods and other motor parts. An interesting feature of the work is the section describing and illustrating the process whereby drop-forgings are made. The whole catalogue is well worth a place at the right hand of the manufacturer and designer.

Pierce Arrow Motor Car Company, Buffalo, N. Y.—The handsome booklet entitled "Routing Suggestions for Pierce Arrow Tourists" would really be a welcome addition to the equipment of any automobilist, whether his car be a Pierce or not. One of the useful features is a tabulation of state license provisions for non-residents—little matters which the prospective tourist often forgets, much to his sorrow. The body of the booklet is devoted to routing suggestions. Each page lists the routes from some one city as a center, indicating them by the intermediate towns and distances; and at the top of each page is a photograph of the Pierce Arrow agency in the city which is taken as the base. The usefulness of the book will not be confined to any one section of the country; the East, of course, is covered very thoroughly, but among the central cities are Houston, Dallas and San Antonio, Texas; San Francisco; Salt Lake City, Utah; Butte, Mont.; Portland, Ore., and Seattle and Spokane, Wash. One of the objects of the booklet, as stated in the introduction, is to place Pierce Arrow tourists in touch with the Pierce representatives in all parts of the country.

Fisk Rubber Company, Chicopee Falls, Mass.—In a 24-page booklet, 4 by 6 in size, the Fisk company describe the construction and operation of the Fisk removable rim. This consists of a specially designed rim which carries the tire, and which is beveled on the outer side to receive the expanding ring. This is shrunk on the felloe in the usual manner. Within the tire rim is a hollow drop center which allows the expanding ring plenty of inside locking contact, as well as making the whole light yet strong. The expanding ring has five bolt holes which correspond to the five holding bolts fitted to the wheel rim. A split in one place allows of sufficient expansion or contraction to permit of wedging the ring in place or removing it. Aside from the space devoted to the rim itself, most of the book is taken up with letters from prominent motorists, who not only use but also advocate the use of the Fisk rim.

The White Company, New York City—White route books are too well-known to require an extended description, and book No. 8 is no exception. An excellent cover is adorned with the view of a toll gate near Wilmington, Del., which reveals some of the picturesque features of the section with which the book deals. This is the Southeast, and two routes are given complete. These are New York City to Richmond and Atlanta to Staunton, covering sufficient territory to allow of the trip from New York to Atlanta without other aid, although there is a gap between Richmond and Staunton. This gap has, however, been described and routed in another previous book, No. 2. The illustrations constitute a well-chosen lot of Southern scenes, all but two or three of the first ones being devoted to that section of the country.

Hoyt Electrical Instrument Works, Penacook, N. H.—This company's neat and business-like catalog illustrates and describes the Hoyt line of voltammeters, voltmeters and ammeters, of the D'Arsonval type for direct current. The instrument which will be of most interest to automobilists is the voltammeter specially designed for use in ignition circuits. It is so wired that both the voltmeter and the ammeter are in circuit during the whole time that the motor is running, and their fluctuations enable one to detect immediately the cause of faulty ignition.

H. H. Franklin Mfg. Co., Syracuse, N. Y.—The purpose of this "Franklin Tourist Book," as stated on the title page, is to help every owner of a Franklin automobile in increasing the satisfaction and decreasing the discomforts of touring. It contains many useful hints on preparing for the tour, the rules of the road, how to prevent trouble, points about the engine, care of tires, etc.

Gospel Auto in Which a Noted Evangelist is to Tour Country

This car was especially designed and built by the Rapid Motor Vehicle Company, of Pontiac, Mich., for T. A. Snider of the T. A. Snider Preserve Company, of Cincinnati, who is actively interested in philanthropic work, and will be used by a well-known evangelist, Miss Anna L. Cartwright. The platform in the rear will be used as the speaker's rostrum.

SOME SELECTED AUTOMOBILE PATENTS

Issue of July 6, 1909.

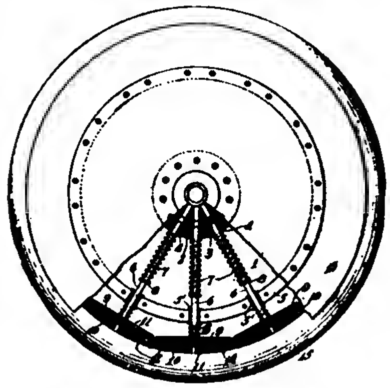
927,355. Tire—Knut Karlström and Gustaf Holmquist, Buffalo, N. Y. Filed May 6, 1908.

This tire has an outer shoe with a rubber base to which is attached a metallic band, the same having a curved cross section to conform with the shape of the outer portion of the time. The metal band is a single strip, being complete around the circumference and overlapping at the starting point. It is covered with canvas on both sides so as to prevent the action of metal on rubber. In order to reduce the weight, which a full band of sheet iron, no matter how thin, would add, a series of oval holes are formed in the metal slip, these being very narrow in the direction of running, and extending nearly to the full width.

Issue of July 13, 1909.

927,511. Spring Wheel for Vehicles—Thomas S. Dunn, Los Angeles, Cal. Filed Nov. 4, 1907.

Spring wheels have excited much interest in the past and appear to be about to attract still more in the very near future. The idea here is spring spokes which carry at their outer ends a series of short sections of secondary felloe. These press against the felloe proper, which, from the nature of the elastic

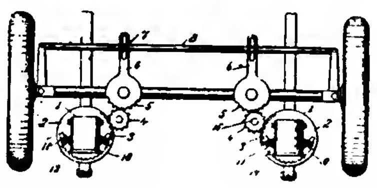


Dunn Spring Wheel, Partly Sectioned

action, must be elastic itself. This elasticity is obtained by making the true felloe in a number of sections equal in number to the number of spokes. It would seem that this method would cause much and severe wear on the inner part of the tire where the outer felloe is divided.

927,619. Automobile Curved-Road Illuminator—Darius W. Wells, Oakland, Cal. Filed Jan. 2, 1908.

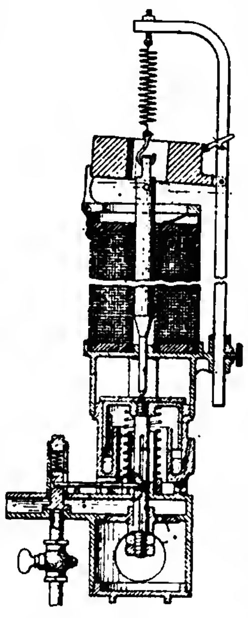
Danger lurks in every turn of the road, as made at speed on a dark night, so, any arrangement for having the lamps turn with the turning front wheels is praiseworthy. Many schemes for doing this have been advanced, but it remained for Wells to use gears to effect the desired result. This he does by attaching to the cross connection, placed back of the axle, a pair of levers, which are connected rigidly at the front end to two gears. These, when rotated, actuate a pair of small pinions, which in turn actuate the base of the lamps, the latter being made with teeth around the periphery for this purpose.



Wells Scheme for Road Illumination

927,541. Electromagnetic Governor for Internal Combustion Engines—Eber Hubbard, Chicago, Ill. Filed Aug. 24, 1908.

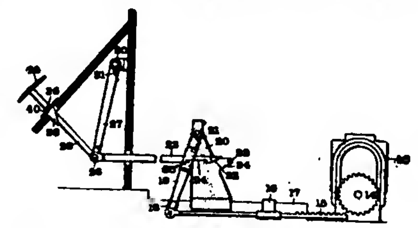
Mechanical devices for regulating the speed of automobile engines have been built and tried for many years, but until recently very few electrical governing methods have been developed. Hubbard has worked out a way of governing, using a solenoid, which works a rod up and down according to the electrical energy passed through the coil. This rod is attached to the throttle and manipulates in that way the fuel entering the cylinders. An evidence of more than ordinary inventor's thoughtfulness is found in a means of detaching both the electrical arrangement and the mechanical substitute, which is also fitted. While the whole arrangement sounds complicated, the drawing shows its simplicity.



Magnetic Governor

927,681. Starting Device for Internal Combustion Engines—Welton H. Rozier and Samuel C. Igou, St. Louis, Mo. Filed Oct. 10, 1908.

With a magneto as a source of ignition and a modern engine, all that is necessary to start the motor is a means of rotating the armature of the magneto at a rapid speed, so as to build up the current very rapidly, resulting in a fat spark. In this arrangement for effecting the desired result, a gear is attached to the magneto armature and is rotated by means of a rack, this being long



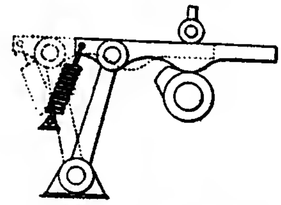
Magneto Starting Device by Rozier

and fastened to the end of a swinging lever. A foot pedal operated by the driver from the seat swings this lever and with it the rack. A tripping device throws the rack out of engagement when the magneto is running normally. The whole scheme looks like the Moon self-starting device.

Issue of July 20, 1909.

928,390. Valve Operating Mechanism for Internal Combustion Engines—Samuel Löffler, Witkowitz, Austria-Hungary. Filed May 26, 1906.

Löffler has pursued the ideas of the earlier Daimler and Peugeot engines, in that the control of the engine is effected by means of a variable valve lift. This is obtained by interposing between the cam and valve tappet rod a sort of lifting lever, which has two straight portions on each side of a cam projection. Normally the cam operates on the cam projection, but to vary the speed, the lever is moved to one side or the other. On one side, the right, the height of the cam

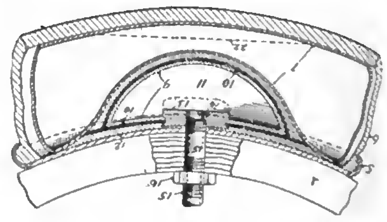


New Form of Valve Operation

is all that is obtained, but on the other side there is a slight multiplying action which makes the lift greater on that side.

928,553. Signal for Pneumatic Tires—Samuel Silverman and Joseph E. Trahan, Watertown, N. Y. Filed Feb. 18, 1909.

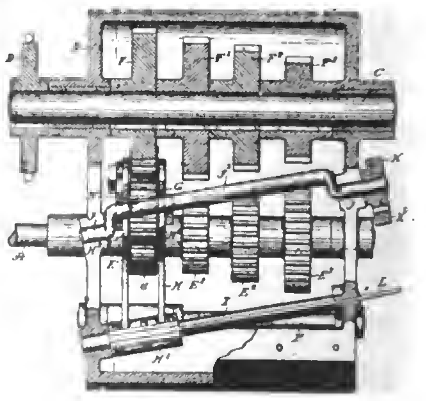
Here, the idea is to apprise the driver of the failure of the inner tube of any tire by attaching to it a whistle, which is blown by the action of the deflated outer shoe pressing on an internal diaphragm. The whistling sound would warn the driver of the car that the tire was punctured and deflated to the extent of the outer shoe pressing upon the diaphragm.



Tire Puncture Signaling Scheme

928,705. Changeable Speed Gearing—Walter Scott, Sheridan, Wyo. Filed Dec. 10, 1908.

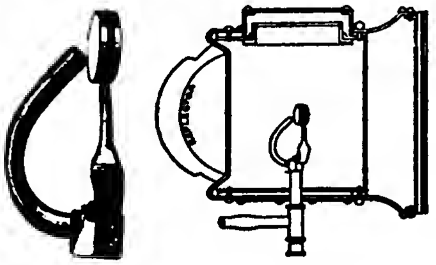
Scott's idea is to move an intermediate gear into mesh with any desired pair of stationary gears, so as to obtain the speed changes. This operating gear is mounted upon a diagonal shaft upon which it is both slidable longitudinally and rotatable in a vertical plane. This construction allows of moving the operating gear up out of mesh, sliding it along to the desired change, then dropping it back into engagement. There is also provision for locking it in any position, as would be necessary with the diagonal shaft mounting, since the thrust of the gears would resolve itself into a sliding motion of slight but measurable amount. As shown, there are four forward speeds provided but no reverse, which would seem to require the use of four gears.



Scott's Transmission in Plan

Information for Auto Users

Wunder Button Lights—An improvement for automobile and motor boat headlights, in the shape of a new burner, has been introduced by the Wunder Button Light Company, of New York. After a number of years of experiment the device has been brought to a stage where its makers state they can prove



NEW BURNER FOR WUNDER LIGHTS

greater efficiency and less gas consumption, the percentages being very high.

The burner is one designed to be exactly interchangeable with the fan tail, and the gas is projected upon a button of material whose composition is a secret of the company. It becomes incandescent under the action of the burning acetylene and oxygen, and projects a wonderfully strong white light, so that the illumination at 2,000 feet is sufficient to light 50 feet on each side of the roadway distinctly. The burner is comparatively simple and anyone can apply it to the gas lamp, in that it has but three parts and they are all assembled for use. The gas is forced through a tiny nozzle, six-thousandths of an inch in diameter, and is mixed with the proper amount of oxygen from the air, through little holes, to furnish good combustion. It is then projected from the rear on the button, and there is no danger of cracking a lens, because the flame is pointed away from it. There is also no danger of soot depositing, because none can deposit at the hole on account of the two pounds pressure behind.

In tests it has been shown that the button light, with a one-quarter foot burner, produces 100 candle-power. A heat of about 2,400 degrees is generated, but it is absorbed by the button, and therefore the danger of cracking the mirror, lens, or glass around the interior is obviated. The buttons are thirteen-sixteenth inches in diameter, held in place by brass clips, and can be changed easily. A different style of burner for those who desire to be able to alter the mixture is being made, and this will have a jacket to regulate the air and a needle valve for the gas.

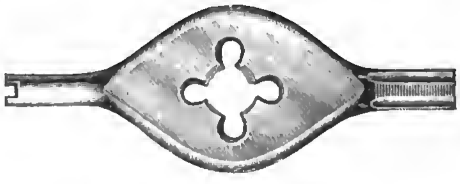
In addition to the button projecting light, the company is preparing to go further with its pencil light, one which radiates and is suitable for interior or street lighting.

The manufacturers claim excellent results with the buttons applied to headlights, and state that there is sufficient dispersion not only to light the road immediately ahead of the automobile, but to project a bundle of rays forward so that twelve telegraph poles (the method of judging a light) can be counted.

New Light Rear Axle—Added interest on the part of the public in small cars has stimulated the parts makers to bring out accessory and parts for this type of car. One of these is the rear axle illustrated herewith. This is a new product from the Long Arm System Company, Cleveland, and is intended for use on cars weighing empty either 2,000 or 2,500 pounds. In the latter case, the axle may be had in the full floating type, while for cars of a maximum weight at the former figure, the construction is changed and the axle is fixed in the hubs. Steel parts are of carefully selected open-hearth carbon steel, while all cast parts are made from malleable iron of good quality and possessing a high factor of strength. Brakes are supplied either single or double, and of 12 or 14-inch diameter. The brake bands are lined with any of the standard non-burnable brake lining fabrics, or the internal band may be had of chilled gray iron. Brake levers are either mounted inside or outside of the springs, as desired. The torsion tube surrounding the propeller shaft is made to specifications as to length, supporting device or diameter.

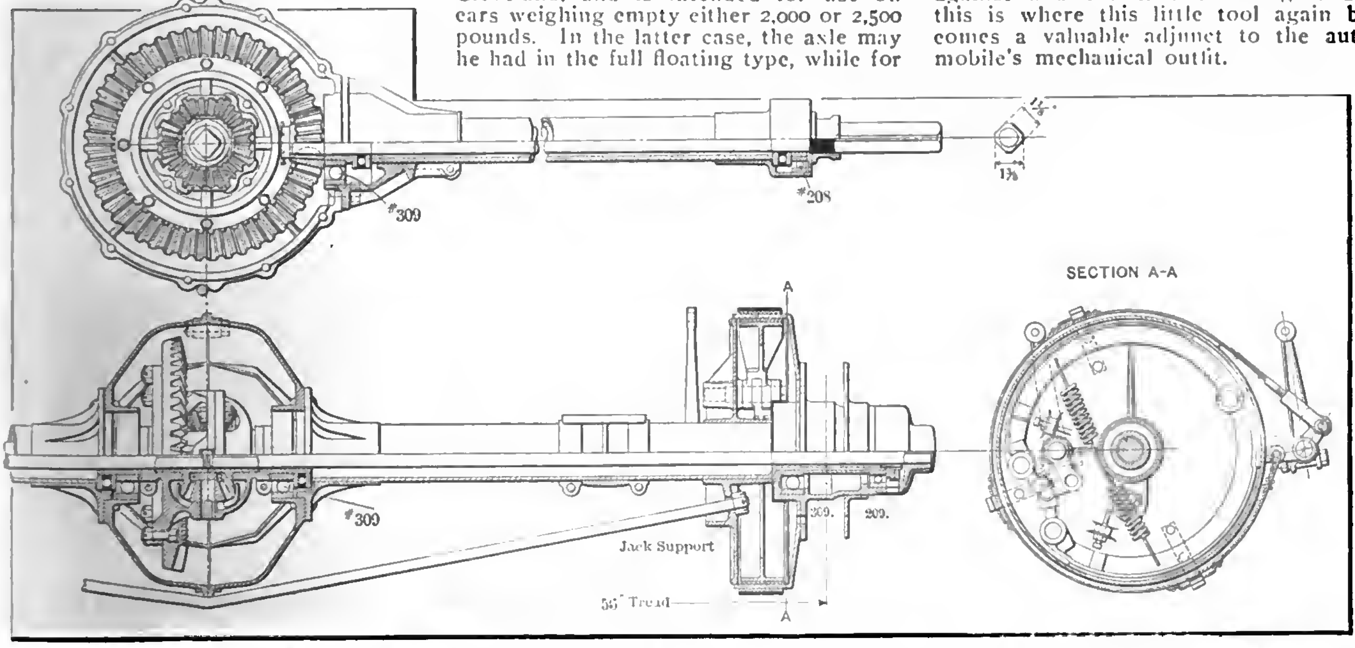
The usual gear ratios are from 2½ to 1 up to 4 to 1, anything between being obtainable. The gears used have wide faces, are of good material and run quietly.

New Tire Valve Tap and Die—This new production of the Motor Car Equipment Company, of New York City, is made in one piece of drop forged and hardened steel, highly polished. It is used for removing the internals of tire



M. C. E. NEW TIRE VALVE TOOL

valves, which through rust and perhaps cutting of threads have become wedged in the valve. When in that condition it is almost impossible to remove them with the ordinary cap valve that is supplied on the valve, but it is asserted this tool removes them with ease. Then, again, when the internals have been removed, the tap end can be used for cutting out a new thread, allowing the repair parts to be inserted. The center portion of the tool is for re-threading the outside of the valve. The cap which fits over the valve is very often knocked against and the thread damaged, and this is where this little tool again becomes a valuable adjunct to the automobile's mechanical outfit.



FULL FLOATING TYPE OF REAR AXLE JUST BROUGHT OUT BY LONG ARM SYSTEM COMPANY FOR LIGHT CARS WEIGHING 2,500 POUNDS OR LESS

THE AUTOMOBILE

Britain's Motor Track Has Entries But Not Crowds

Start of the Relay Race in the Recent August Holiday Meeting at Brooklands Track, England

LONDON, Aug. 12—Brooklands promises to regain its proper position as the most popular, as well as the largest and fastest automobile track, if its managers can continue to provide such close and speedy racing as was seen at the recent two-day August meet. Although the general public had not forgotten last year's uninteresting exhibitions and was chary of its patronage, there was still a by no means inconsiderable attendance of the track's hardy habitues. The weather, too, was threatening. But several of the finishes were as close as human handicappers could hope to obtain, and were fought right up to tape. Nearly every one asserted that Saturday's sport, in particular, was the best ever seen since the opening of the track.

For the first day five car races and three for motorcycles made up the program. In the August Junior Handicap came one of the best finishes ever seen at Brooklands. Mr. Colmore and his 24.8-horsepower Darracq, starting from scratch, made up his distance on the five-and-a-half-mile double circuit, and succeeded in passing the other eleven competitors, snatching the victory by a hair's breadth from Roy Fedden on the Straker-Squire. Motorcycles had their innings in the third race, and another scratch man, Lee Evans, on his American Indian, put the race away on the finishing straight. The only race which was really disappointing was the July Junior Handicap, in which a little Sizaire "one lunger," which was sent away first, developed an unexpected burst of speed, and far from being overtaken, opened up a wide gap on the other competitors. It was a runaway win at an average speed of 44 miles an hour for the double circuit.

The two-mile sprint race was expected to furnish some fast time, as entrants were required to have an official record of 80 miles an hour. Unfortunately, Mr. Stirling's Brasier went out of commission on the way to the track. Although the time was not quite as fast as might have been expected, for Sir George Abercromby's Napier fell short by five miles of its previous achievement, the race was nevertheless a good one, calling for skilful work on the part of the drivers in securing the best acceleration.

The July Senior Handicap added another win to the already long record of O. S. Thompson's reliable Austin "Pobble," although the Abercromby Napier was in the lead and within a few hundred yards of the tape when an ignition connection broke. It finished coasting, just beating out an Itala for second place. Lee Evans and his Indian scored again at 60 1-2 miles an hour in the Senior Motorcycle handicap.

The final event was a relay race, a form of contest which rarely fails to be close and interesting. Two cars form a team; when the first completes its circuit the driver passes his voucher to his team-mate, who then makes the second circuit. Here the Austin "Pobble" came to the fore again, its running mate being P. C. Kidner's 20.1-horsepower Vauxhall. Thompson led throughout the first lap, but overshot the finish line, and had to get out and run back on foot to pass the voucher. Second place went to the Abercromby Napier, mated with Bray's little Sizaire. Although Abercromby was next to last to get away for the second lap, he was rapidly overhauling the Vauxhall on the homestretch. There was quite a thrill when one of the drivers, in going out of the straight, got high up on the banking and came within an ace of slipping down again. These team events have proved so successful that they will probably have a permanent place on the Brooklands programs.

Monday's racing seemed rather anticlimactic after Saturday, although in itself above the average. Perhaps this was due partly to the weather. Even the most optimistic felt that it would be necessary to put up with a showery afternoon, but although the clouds remained black and threatening, the rain still kept at a distance.

The comfortable entry of twenty-five cars in the August Senior handicap necessitated running the race in heats, for the first time this year. Mr. Thompson secured the first heat with "Pobble," and Mr. Hammond with the low, flat-shaped gray Lagonda, a newcomer to the track, was second. The next heat was won by Sir George Abercromby's Napier at a speed of 84 miles an hour, followed by Mr. Paton's Darracq. The final went to "Pobble," with 2 minutes 27 seconds allowance, at the rate of 69 3-4 miles an hour. The Napier, from scratch, was a good second and the Darracq third.

After two motorcycle races had been disposed of, with a result of a third victory for the Indian, the field was made ready for the second Grand Prix race. This turned out to be a great disappointment. Mr. Stirling's Brasier had failed to appear, owing to stripped gears, so that the contestants were reduced to three. The starting gate was used for this race. At the rise of the gate, Mr. Loder's big red Itala jumped to the fore, but stopped at the first corner for lack of gasoline, as was afterwards explained. The Weigel, driven by Mr. Whittaker, did not come up to form, leaving the race to Mr. Astley's 59.2-horsepower Napier in easy fashion. The average time was 86 1-4 miles an hour.

For the second race for the O'Gorman trophy, the rules stipulated that the rating of the competing cars was not to exceed 21-horsepower nor the stroke 121 millimeters. The race was to be a long one, 28 miles, and at first it appeared as if it would be another battle royal between those old rivals, the Vauxhalls and the Talbots. Both the latter cars, however, had ignition trouble which put them out of the running, and thereafter the race lay between the two Vauxhalls. That of Mr. Hancock won by a few feet over its team-mate, driven by Mr. Kidner, at the rate of 70 3-4 miles an hour. There was no limitation as to the use of fuel, and Mr. Stewart's Lancia took advantage of this by fitting an oxygen cylinder to feed the carbureter. He did not appear to gain any great advantage by it, however.

The last event on the card, the August Winners' handicap, was finely contested, and won great praise for the handicappers. The principal contestants were the two Napiers, the Vauxhall, and the Indian motorcycle, and the latter secured its fourth well-deserved win. With an allowance of 1 minute 45 seconds on the 5 1-2 miles, it just kept ahead of Mr. Astley's 59.2 Napier from scratch.

In short, it was a most successful meet, even with the small attendance, and every one is looking forward to the next one, to be held October 2. Then, it is expected, Brooklands will at last be free from its last vestige of ill-luck.

PARTRIDGE TRIED BROOKLANDS TRACK

New York, Aug. 14—E. S. Partridge, of Wyckoff, Church & Partridge, returned this week on the *Adriatic* from his European trip, during which he visited France and Germany, besides spending a week in England. While there he sampled the Brooklands track in the Stearns touring car which he took abroad with him. One of his companions in the eighty-miles-an-hour ride was James G. Holland, a newspaper man well known here in the early days of automobiling. According to Mr. Partridge, the Brooklands course is perfectly banked, and he did not feel the least bit of hesitation in encircling it at racing speed. On his return voyage he ordered by wireless one of the W. C. P. yellow taxicabs to meet him at the dock. This so interested other passengers that they did likewise, and the entire reserve squadron was necessary to satisfy the demand.

ONE-MILE TRIALS FOR LONG BRANCH

Long Branch, N. J., Aug. 16—Ocean avenue will on Saturday be the scene of a series of mile time trials by automobiles, as a part of an athletic programme arranged by the local board of trade. The city authorities have given permission to close the boulevard to the public, and sanction has been obtained from the A. A. A. for the meet. Prizes of cash, statuary and cups, representing a total of nearly $5,000, will be awarded, and from present indications there will be a large entry list of New York and Jersey coast autoists. The road is well oiled and there is an extra three-quarters of a mile, part for a flying start and the rest for the finish. The committee: M. G. Kahn, M. R. Rothschild, Failing Baruch, C. L. Bowler, Jr., H. A. Content.

LATEST NEWS OF THE MUNSEY TOUR

Washington, D. C., Aug. 14—Frank H. Trego, secretary of the Chicago Motor Club, has been selected as chairman and referee of the Frank A. Munsey reliability contest to be run September 21-29 from this city to Boston and return. Mr. Trego is one of the best posted technical men in the country and enjoys the confidence and esteem of automobile manufacturers and automobilists generally. With Mr. Trego at the helm, contestants will be assured of having the tour conducted properly. Nineteen cars have been entered in this tour to date, and the probabilities are strong that the number will be increased to 35 before the entries close at noon on September 11. The latest additions to the entry list include two Croxton-Keetons, entered by the Croxton-Keeton Motor Car Co., Massillon, O.; a Spoerer, entered by the Spoerer's Sons Co., Baltimore; a Corbin, by the Corbin Motor Vehicle Co., and a Columbia, by Frank P. Hall, of this city. The latter is the first private owner to enter the tour. The pathfinders who are blazing the route in a Chalmers-Detroit reached Boston early in the week and are now en route home by way of New York.

GUTTENBERG TRACK TO BE MOTORDROME

New York, Aug. 16—Up on the palisades of the Hudson where the natural rock forms a hard foundation, is the old Guttenberg track. This was one of the first in the country to be used for automobile racing, many years ago, and now it is to be rebuilt into a modern motordrome, with banked turns and concrete surface. The Palisade Automobile Association acts as the promotor. A schedule is being prepared.

"Zodiac III," a New Type of Dirigible, Making Its Experimental Flights at St. Cyr, France

AMERICANS ARE CONCERNED IN EUROPEAN AERONAUTICS

PARIS, Aug. 13—Automobile America is pretty well represented in Paris at the present moment. As aeronautics have taken first place, and indications are that the building of aeroplanes can now be classed as an industry, it is but natural that leaders of the American automobile industry should look closely into the aeroplane as a prospective field for commercial activity. One evening this week, among a group of Americans who had gathered at Issy-les-Moulineaux to watch Bleriot teach one of his pupils to fly, three American factories were represented. Roy D. Chapin, general manager of the Chalmers-Detroit Motor Company, watched the proceedings closely and looked into the details of the Anzani engine. L. H. Kittredge, president of the Peerless Motor Car Company, kept an equally open eye. Charles Y. Knight, who has just come over to Paris from a huge success in England, was the Chicago member of the group. Frank S. Lahm still claims America as his country.

J. N. Willys, of the Overland Automobile Company, is another American manufacturer who passed through Paris this week and left for an extended tour through France. Jefferson de Mont Thompson, ex-chairman of the Vanderbilt Cup Commission, after

Group of Americans Watching Bleriot Flying at Issy-les-Molineaux—Messrs. Chapin, Kittredge and Lahm Are Included in the Group

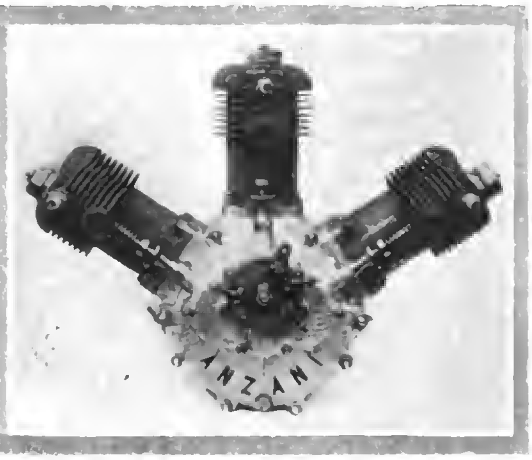
Side View of Anzani



Front of Anzani 25-H.P. Aero Motor

spending a couple of weeks in the capital, left for a tour through Germany and Holland, but will return to France in time to witness the aeroplane races at Rheims this month. Messrs. Chapin and Kittredge also intend to be spectators at the Rheims gathering, the week of August 22-29.

Cortlandt Field Bishop, president of the Aero Club of America, who has been over here most of the Summer, is now busy making arrangements for the reception of his flying machine to be piloted by Glenn H. Curtiss at Rheims. This will be the only American flying machine taking part in the big French races. David Bruce Bishop, brother of the president of the Aero Club, is dividing his time between watching the various French aeronauts and piloting the fast hydroplane boat produced by W. H. Fauber, formerly of Chicago. The Packard Motor Car Company has one of its representatives here in C. G. Moors, general works manager.

Active Preparations for Aeronautical Salon

The opening of the Paris Aeronautical Salon, to be held in the Grand Palais, has been fixed for Saturday, September 25. The closing day is at present Sunday, October 17. As, however, the hall is not needed for any other event, there is a possibility of the show being continued, if this is found desirable. The aeronautical Salon this year replaces the automobile show, abandoned after eleven consecutive years of existence. Last year the aeronautical section joined forces with the commercial vehicle Salon, each of them having a half of the hall. The 1909 exhibition is the first one held exclusively for aeronautics, and will be the first purely aeronautical exhibition of real importance held in the world. All the plans for the show have now been drawn up, the center of the hall being occupied by a spherical balloon, with a dirigible of the Republique or Ville de Paris type to left and right of it. In the centre of the floor space, under the dome, will be a number of stands of honor, important among them being one reserved to the Bleriot aeroplane which flew across the English Channel.

CURTISS ARRIVES, READY TO COMPETE

Paris, Aug. 12—Glenn H. Curtiss arrived here to-day with his aeroplane, and left immediately for Rheims, where he will compete in the International Aviation Cup race on August 28 as the representative of the Aero Club of America. He is carrying the aeroplane as "personal baggage," so as to lose no more

Comte de la Vlaux (with canes) and Constructor Mallet

Sommer in Driver's Seat of His New Record Breaker time than possible, and hopes to have it set up to-morrow in time to begin his practice flights and get acquainted with the ground. After the Rheims meet is over Mr. Curtiss will proceed to Brescia, Italy, and will take part in the aeroplane races there.

Curtiss Repairs Quickly

RHEIMS, FRANCE, Aug. 17—In a test flight yesterday Curtiss' motor stopped and he had a severe fall, painfully bruising one leg. He had already made two short flights of two minutes each. The aeroplane was thought to have been seriously damaged, but under Curtiss' supervision it has already been completely repaired.

NEW McCURDY FLYER

PETEWAWA, ONT., Aug. 14—J. A. McCurdy and F. W. Baldwin, formerly connected with Dr. Bell's Aeronautic Experiment Association, whose successful *Silver Dart* was wrecked here August 2, have completed a new machine after the same model, which has been tested with good results. It is called the *Baddeck No. 1*. No extended flights were made, but it was proved that the motor and propellers worked properly and that the arrangement of the surfaces was correct. If the trials here come up to expectations Messrs. Baldwin and McCurdy will probably go to England and attempt to win some of the prizes offered for British aviators.

Willard Making American Record for Cross-Country Flight, on Long Island

WILLARD FLIES 12 MILES CROSS-COUNTRY

Charles F. Willard, who is operating the Aeronautic Society's Curtiss aeroplane, made a new American record for cross-country flight last Friday. He remained in the air nineteen minutes and thirty seconds, and covered a distance of approximately twelve miles in an irregular square, from the grounds at Mineola, L. I., over Garden City, Westbury, Hicksville, and back to within a mile and a half of his starting point.

The motor was started for the flight about 5 o'clock in the morning. The aeroplane rose gracefully in the air, reaching an elevation of 100 feet as it passed over the trees and telegraph wires at the edge of the grounds, and then headed straight across the plain toward Garden City. For eight or ten minutes the machine was out of sight of the spectators at Mineola. Hardly had he reappeared, traveling at forty miles an hour, when the motor stopped, and Willard brought the machine to earth in a smooth glide. The stoppage was caused by a broken camshaft in the motor. Willard's successful landing was as much of a triumph in its way as his flight. It will be remembered that he received his first lesson from Glenn Curtiss July 18, never having been in an aeroplane before. Since that day he has steadily increased the length of his practice flights and has been uniformly successful, never having had a serious accident.

U. S. NAVY WANTS TO TRY AEROPLANES

WASHINGTON, D. C., Aug. 14—The Navy Department, not to be outdone by the War Department, wants some aeroplanes of its own, and specifications have already been drawn up. Unless Secretary Meyer disapproves—which is not likely, as he was one of the most enthusiastic attendants at the Wright trials—bids on two aeroplanes will probably be advertised for in the near future. The Navy specifications will call for some sort of landing boats sufficiently buoyant to keep the machine afloat if it is forced to alight on the water. The experts see no difficulty in launching an aeroplane from the deck of a battleship; it is pointed out that a fast cruiser will attain sufficient speed to cause an aeroplane to rise from its deck without the use of any special devices. The problem now is to find some way to enable the machine to return to the deck without injury. If the aeroplanes can be made to carry a searchlight they will be almost invaluable for naval operations.

The ground for the new training ground at College Park, Md., has been leased, and work has been started to put it in condition for Wilbur Wright's future flights.

Sommer Aeroplane Which Recently Broke World's Endurance Record in France

INDIANAPOLIS SPEEDWAY TO HAVE ITS GREAT INITIATORY

INDIANAPOLIS, IND., Aug. 16—Everything is in readiness for the opening automobile events on the Indianapolis Motor Speedway, which will be held Thursday, Friday and Saturday of this week. The entry list now numbers sixty-two cars, with the probability that it will grow to more than seventy before Thursday, when the list closes.

Seldom has such an aggregation of drivers been seen at a meet as will appear at the Speedway during the three days. Chevrolet, Dennison, Strang, Oldfield, Zengle, Christie, De Palma, Hearne, Knipper, Lorimer Burnham Ryall, Aitken, Drasch and De Witt are among those who will drive.

When the motoring army invades Indianapolis this week it will be treated to a great surprise party in the way of this great speed enterprise, which is even more stupendous than one imagines in his mind's eye before seeing it. The plat of ground on which it is located is 1 1-2 miles in length and 1-2 mile wide, containing 320 acres of ground. Inside those whitewashed fences is a racing plant complete, on which has been spent at least $400,000 and into which has been inculcated every modern idea in a speed way that such enthusiasts as Messrs. Fisher, Wheeler, Newby and Allison could conceive. A bird's eye view of the layout shows two tracks—one a huge oval, 2 1-2 miles in length and enclosing another which is a sinuous, twisting thing, bending here and curving there until it covers fully as much ground as does the outside circuit. This is the basis of the plant, but everywhere else on the grounds there is more evidence of thought and care in providing not only for the convenience of the manufacturer wishing a place where he can try out his product as well as for the comfort of the spectators.

The main entrance to the ground is at the southwest corner, and a road runs directly from the front gate to the main grand stand, a commodious structure, which is covered and which will hold 10,000 people without crowding. This is not the only provision made for seating the spectators, though, for ranging around the south turn are thirteen miniature grand stands intended for private parties, each of which will hold twenty-eight people. Then, in about the middle of the south turn is another big stand—the bleachers—which will hold 4,200 more.

Aside from the grand stands, there are many other features of the plant, not the least of which are fifteen garages which are to be used by the racing teams, each of which will have its own garage, which will be fitted up with tool bench and other facilities for tuning up cars. These garages vary in size, from one car up to a dozen, the big one being located outside the larger track. The others are bunched in a picturesque position just south of the south end of the inner loop and only a few hundred feet away from the finish line. Each garage is painted green, with white trimmings, and the doors are the full width of the building. Leaving this feature, one finds a row of repair pits on the inner side of the outside track. There are twenty-five of these repair pits, half on one side of the judges' and press stands and the remainder on the other side. These pits are nothing more or less than huge boxes without a cover.

Every effort has been made to make the officials' stand complete in every detail. It is located at the tape and between the main and inner tracks. It is a three-story affair, boarded up on all sides and with slanting wooden windows which will keep out the glare of the sun and the rain if the weather man becomes perverse. The press stand, right alongside, is designed with the same care, there being accommodations for about sixty newspaper men and operators. The man who takes pictures is not overlooked, either, for the ground floor of this pretentious establishment contains a dark room where pictures may be developed. From this press stand, as well as from the judges' stand, one may look at any corner of the track, the windows being on all sides. The only obstruction to the view is a bunch of trees at the northern end of the grounds—a small wood in which may be parked cars if it is found there is not enough room in the vast expanse of infield, which offers 180 acres of space for parking spaces.

Now as to the course itself. Most of those who follow racing matters know that the Indianapolis speedway consists of an outer track 2 1-2 miles in circumference, while another one of similar length occupies the infield. Both are surfaced alike, but the idea of the winding track is to secure conditions approaching what is to be found in the open country. The turns on this course are not banked, but are so gradual that it ought not to be any trick at all to hold them at top speed. This inside course will not be used for the meet this week, for it is not done as yet, but when it is completed it will make a pleasing variation to see a big field of cars strung out over the two courses, which might well be likened to a magic maze.

Every effort has been made to finish the outer track, but it has been only by the hardest kind of work that the task has been accomplished. Night and day of late the men have been working, the track at night being lighted with Prest-O-Lite gas tanks. By this kind of labor the speedway was ready for the motorcyclists, but now comes the job of refining it for the motor car races.

Upon the shoulders of P. T. Andrews, an engineer from New York City, has devolved the job of finishing this work, and right well has he stuck to the job. At times he has had as high as 450 men working, and besides this has employed five steam tractors, 300 mules, 150 scrapers and four 6-ton and three 10-ton rollers. The result of this is an outside track 2 1-2 miles in circumference and with four curves. The banking is 20 per cent. At each end—the north and south—there is a 660-foot turn, and each of the straights measures 3,300 feet. The banking itself is unique, and it is doubtful if anything like it ever has been used in track construction. The track itself runs up 50 feet from the pole, and at this point there is another smaller banking, which is termed a cap, and which rises two feet in 10, making a sort of a bumper or fender. A car can run on it if necessary, but the tendency seems to be to stop skidding in case a car hit it. To further safeguard the turns and prevent any distressing accidents which would result if a car ran off the track, there is a small board fence 24 inches in height, at the cap, which is scientifically designed so that a car skidding up to it will strike the hub caps instead of the wheels, thus holding the car on the track. The banks themselves are 12 feet in height, while the radius of the curves is 840 feet.

In building the track Engineer Andrews first used clay for a base and then put on a top dressing of taroid macadam. At the present time the top dressing needs traffic to smooth it down, but by the time the second meet is held it ought to be lightning fast. Some of the skeptics who have noticed this declare that the big cars will tear up the surface, but this is scoffed at by Engineer Andrews, who declares he has tested the surface and not found it wanting. He points out that 500 teams hitched to narrow-tired vehicles have run over it without injuring the surface, and that a big wagon loaded with 3,500 pounds of stone had failed to leave a trace of its passage.

"I never have seen Brooklands track in England, but I have had correspondence with the people who built it, and also have studied the plans," declares the engineer. "I believe we have a track that will be faster and safer than Brooklands. The English speedway has no fixed radius and easements, while it is flat on the pole. You will notice that our track gives a car a fixed position at any and all angles. A car has the same position on the banks as on the straights, while the approaches are so laid out that it is possible to hit them at 100 miles an hour without skidding. On this track there is no tendency to climb a grade when on the turn, as I have demonstrated to my own satisfaction by tests with weights on different tracks and cars."

Willie Haupt and His Winning Alco "60"

Referee S. B. Stevens

DePalma and Fiat That Won Free-for-Alls

QUAKER CITY "SHOCK ABSORBERS'" MIDSUMMER MEET

PHILADELPHIA, Aug. 14—"The Shock Absorbers," a body of local automobile writers, to interrupt the deadly monotony of a usually meetless month, took a chance to-day and ran off a midsummer race meet and gymkhana at Point Breeze track. The affair was well conducted, but it cannot be said that Philadelphia enthusiasts manifested a proper degree of appreciation of the efforts of the committee to furnish entertainment along gymkhana lines. The Quaker public showed that it preferred action for its money, and during the long-drawn-out preparations, with barrels and wires, potatoes, and spears among the "props" necessary to pull off the stunts, the crowd kept its good humor by audibly criticising the contestants and the management's efforts to amuse them.

The track was as dry as a chip, and the practice previous to the races cut up the turns until they were inches deep in dust. Big fields were an impossibility, and at one time Referee Stevens and Starter Wagner seriously considered postponing the 50-mile Point Breeze Marathon to give the watering carts a chance.

The Marathon, at fifty miles, furnished the only thrills of the day. There were four starters—Heitemeyer's Simplex "50," driven by Frank Lescault; a 70-horsepower Welch, driven by Erwin Bergdoll; American Locomotive "60," with Willie Haupt at the wheel, and the little 18-20 Lancia, Al. Poole driving. Getting away to a good start, Lescault soon forged to the front, followed by Haupt, Bergdoll, and Poole, in the order named. The Simplex steadily increased the daylight between it and the Alco, until, at the end of the thirtieth mile, Lescault was leading by nearly half a mile, the other two cars, which were apparently very evenly matched, having been lapped once by the leaders. Lescault maintained his advantage until the thirty-fifth mile, when, in negotiating the particularly soft and dusty turn leading into the back-stretch, the car plunged into and through the fence, fortunately catapulting its driver and mechanician onto the grass before turning turtle. Neither suffered anything worse than a few scratches and a general shaking-up.

With the Simplex out of it, Haupt and the Alco took the lead, and with a lap advantage on the others, easily retained the position and landed a victory by a lap and a half. Al. Poole made a sturdy fight to snatch the place from Bergdoll, and the big Welch was just 20 seconds too fast for the little Lancia.

Ralph DePalma was the "big smoke" of the day. In the five-mile free-for-all, which was run in heats, best two in three, he staved off his only opponent, Frank Lescault, in the Simplex "50," and won in the comparatively slow time of 5:35 2-5 and 6:02. In the 10-mile handicap, however, he gave the spectators a run for their money. He had to, for Al. Poole, in the Lancia, was given a start of 1:20, and Harry Davis, in the Moon, 1:45. It took seven laps and a half to catch Poole, the leader, and resulted in a new 10-mile record for the track—10:59.

The $1,251 to $2,000 five-mile race for the Frank L. Poth cup resulted in an easy win for the Oldsmobile "35," driven by Tom Berger. Wilkie's Buick dropped out owing to ignition troubles, and Borie's Mitchell did not have sufficient speed to compel Berger to exert himself. The latter, however, met his match in the ten-mile $2,001 to $3,000 race, when Harry Davis drove his 30-horsepower Moon to victory in 12:56.

The one-mile city speed limit test gave the spectators an idea of the ridiculousness of such a gait, and the veritable crawl of the eleven entrants around the mile oval was greeted with a continuous sally of witnesses. No speedometers or watches were permitted in the cars. "Jimmy" Florida, the Vanderbilt and Fairmount Park race driver, was the best guesser of the lot, landing his Locomobile "20" at the tape just two seconds short of the exact time, with George Daley, in a Woods electric, second; and W. B. Dannenhower, in a Franklin, third.

The good-natured crowd greeted the gymkhana stunts with a volley of sarcastic remarks, apparently being of the opinion that such tomfoolery was a waste of valuable time.

Ralph DePalma made two unsuccessful attempts on his own mile record for the track (1:01 4-5). The summary:

50 MILES, POINT BREEZE MARATHON—Q. C. M. C. CUP

No.	Car	H.P.	Driver	Time
1	Alco	60	Willie Haupt	:59:32
2	Welch	70	Erwin Bergdoll	1:01:10
3	Lancia	18-20	Al. Poole	1:01:30

10 MILES, $2,001 TO $3,000—GEORGE H. STETSON CUP

1	Moon	30	H. Davis	12:56
2	Oldsmobile	40	Tom Berger	

5 MILES, $1,251 TO $2,000—FRANK L. POTH CUP

1	Oldsmobile	35	Tom Berger	7:57
2	Mitchell	30	Cherie Borie	

10 MILES, HANDICAP, FREE-FOR-ALL—HOTEL WALTON CUP

1	Fiat Cyclone (Scr.)	60	Ralph DePalma	10:59
2	Lancia (1:20)	18-20	Al. Poole	
3	Moon (1:45)	30	H. Davis	

5 MILES, FREE-FOR-ALL—M'DONALD & CAMPBELL TROPHY

FIRST HEAT:

1	Fiat Cyclone	60	Ralph DePalma	5:35 2-5
2	Simplex	50	R. Heitemeyer	

SECOND HEAT:

2	Simplex	50	Ralph DePalma	6:02
1	Fiat Cyclone	60	Frank Lescault	

MILE TIME TRIALS FOR TRACK RECORD (1:01 4-5)

1	Fiat Cyclone	60	Ralph DePalma	1:01 4-5
			Second trial	1:02

1 MILE, SPEED LIMIT TEST, 12 M. P. H.—BAILEY TROPHY

1	Locomobile	20	J. W. Florida	5:02
2	Woods Electric		G. W. Daley	5:19 3-5
3	Franklin	18	W. B. Dannenhower	5:30 3-5

GYMKHANA FOR FIRESTONE TROPHY

1	Buick	18	Eddie Wilkie	
2	Simplex	50	Frank Lescault	
3	Oldsmobile	35	Tom Berger	

LOWELL BUSY ON NATIONAL STOCK CAR RACES

LOWELL, Aug. 16—Rapid progress is being made by the Lowell Automobile Club in its preparations for the automobile carnival the week beginning September 6, and everything promises to be in the best of shape for the national contests. The racing cars and drivers are not expected until about August 23, but the A. A. A. contest committee has already taken up its headquarters on the course, between the grand stand and the Vesper Country Club. Several of the racing teams have engaged their quarters, and people anywhere near the circuit who have barns that are not occupied find them in great demand by the manufacturers whose cars will be in the races.

Though the Merrimac Valley 10.6 mile circuit was considered extra fine last year when the first race was held, the Lowell club officials have not been content to leave it as it was, and in all parts of the course repairs are being made which will tend to make it faster and safer than before. Wherever it is necessary the roadway has been widened, the surface scraped and smoothed, corners changed and rebuilt, and before practice begins the whole will be treated with dust-laying preparations.

The Lowell boulevard, a mile stretch from the lower or city end of the course to the grand stand, has been smoothed and rolled and will be treated with heavy asphalt oil and covered with a thin layer of sand, making a resilient but dustless surface. Beyond this broad stretch, where three or four machines abreast can be driven at the highest speed of which they are capable, is about four miles of State road with a surface as smooth as could be desired, and without grades of any consequence. There are, however, a deceptive S curve and other curves, but they will offer no difficulty to the drivers after a little practice. Over this stretch the cars can make fast time and there is plenty of room to pass anywhere.

No Longer a Speed-Reducing Hairpin

At the end of the State road is the upper turn, a veritable hairpin. Last year this presented much difficulty to the drivers attempting to take it at speed because of a large tree that stood just at the point of the turn. This tree has been cut down and the road widened about twelve feet with a gentle slope toward the inner side, giving in effect a banked turn with a macadamized surface. The cars ought to be able to take it without shutting off very much. This turn is regarded as one of the spectacular spots on the course. After swinging around the hairpin turn the cars will enter the back stretch, Varnum avenue, at this point a country road with a dusty surface. It has been widened on both sides and the dust is being scraped away. Oil, which will be used on the State road, as well as on the boulevard, is not considered the proper treatment for this stretch and calcium chloride will be supplied. This part of the course is in the town of Tyngsboro and until the Lowell city boundary is reached, a distance of perhaps two miles, the surface is not of the best, though it will be smooth for the races. The road is winding, with one long climb: in this stretch the road has been built out in places, menacing ledges have been blasted away, and trees too near the highway have been cut down.

The worst place on the homestretch is "the dip." Approaching on a slight curve the driver finds himself on the edge of a precipitous drop with a small bridge at the bottom followed by a long climb, with a curve at the end. Cars took this at forty miles an hour last year but this year they should be able to go even faster, for the rocks that stuck out to the edge of the road at the top of "the dip" have been blasted away, the road down the declivity has been materially widened, and the bridge changed so that there will be no bump.

Reaching the city line the road changes to excellent macadam. It is winding but broad, with little grade. At the lower end for a few hundred yards there is a single car track, but there are macadam driveways of sufficient width on both sides of the flush rails. The cross over from the back stretch to the boulevard is a street with right angle turns at both sides. To prevent the tearing away of the surface at these turns and consequent deep ruts, the Lowell club is having both of them resurfaced with heavy macadam. The back stretch, with the exception of the upper end, and Dunbar avenue will be treated with oil.

A Presidential Box in the Grand Stand

The grand stand, seating 5,550 people, is nearly finished. Opposite the starting line in the middle of the stand is a special box for President Taft and party, who have been invited to witness the races. From all parts of the grand stand there is a fine view down the boulevard and up the State road. Opposite the grand stand is a commodious official and press stand and this will be connected with the grand stand by an overhead bridge, upon which the score boards will be located. A telephone system is being installed around the circuit and telegraph wires will run to the press stand. Near the main entrance of the grand stand is one end of a pile and pontoon bridge that is being constructed across the Merrimac river. On the other side the Boston & Maine railroad company has built a wide platform upon which passengers from the special trains will be disembarked. From there they may cross the bridge directly to the course. Persons arriving on street cars will also be landed at the end of the bridge. Spaces have already been staked out for 5000 automobiles along the boulevard, on the opposite side from the grand stand, and excellent arrangements have been made for reaching these parking spaces.

The entry blanks for the mile sprint races on the boulevard Tuesday afternoon, September 7, have just been sent out. These provide for eleven events, five for stock cars under the A. A. A. price classification, four for stock chassis under the A. A. A. piston displacement and weight classification, a free-for-all and record trials. The entry fee is only $15 so a very large field is expected. Bronzes, shields or sterling cups will be given as trophies in all these events. Flying start will be permitted.

The complete programme for the carnival is as follows:

Monday Sept. 6, 10 a. m.—National small stock chassis competition in three classes at 127.2, 159, and 212 miles, to be started together for the Vesper Club, Yorick Club, and Merrimac Valley trophies and $2,700 in cash prizes. Fireworks in the evening from the temporary bridge over the Merrimac river near the grand stand.

Tuesday, Sept. 7, 2:15 p. m.—Speed trials, mile straightaway with eleven classes, including free-for-all and record trials.

Wednesday, Sept. 8, 10 a. m.—National stock chassis race, distance 318 miles for the Lowell trophy and $2,100 in cash prizes.

Thursday, Sept. 9, 10 a. m.—National Marathon run over the Merrimac Valley course, distance 26 miles. Motor boat races on the river and athletic sports in the afternoon.

Friday, Sept. 10, 10 a. m.—Meeting of the American Federation of Motor Cyclists, six events for $600 in prizes.

Entries are coming in thick and fast. Nineteen additional entries were made on Saturday last, which augments the already large list considerably, and a score or more are expected within the next few days. Those made last Saturday include a string of ten Buicks, to be driven in the various events by Louis Chevrolet, Strang, Burman, Ryall, DeWitt and Arthur Chevrolet; three Maxwells: one Moon, to be driven by Harold Brinker, the western crack; one Allen-Kingston, a Columbia, an Isotta, an 18-horsepower Mercedes, a Bergdoll and a second Apperson. Paul Lacroix has decided to swell the list of foreigners by putting a second Renault among the contenders, with Charles Basle as the pilot.

Walter Christie has entered his new 100-horsepower front-wheel drive racer in the mile straightaway competition and time trials, and Mrs. Cuneo will have her Knox "Giant" in the same, driven by Louis Disbrow. Numerous manufacturers have promised more entries, which will not be announced until the checks for entry fees are paid.

Practices in Water-Cooling
Chapter II

INDIRECT COOLING involves the circulation of a liquid, as water, the function of which is to absorb heat from the cylinders and deliver the same to a current of air, which is passed over the surfaces of a radiator, within which the water, in its heated state, is circulated, for which purpose a pump is used excepting in the cases involving the thermo-syphon principle of circulation. Water-cooled motors, so called, are all of the indirect system, and this is quite independent of cyclic relations, etc. In indirect cooling there are several considerations, as follows:

(A) The specific heat of the liquid.
(B) Boiling point of the liquid.
(C) Difference in temperature of the cooling medium.
(D) Internal surface of cylinder exposed to heat.
(E) Thickness of the cylinder wall.
(F) External surface of cylinder wall submerged.
(G) Conductivity of the metal of the cylinder wall.
(H) Ability of circulating pump or equivalent means.
(I) Internal (wetted) surface of the radiator.
(J) Thickness of walls of water tubes in radiator.
(K) Conductivity of the metal used in the radiator tubes.
(L) External surface of radiator exposed to air.
(M) Efficiency of the radiating surfaces.
(N) Ability of the air propeller.
(O) Distribution of the stream of air circulated.
(P) Specific heat of air.
(Q) Difference in temperature of air circulated.
(R) Effect of "gills."
(S) Effect of incrustation.
(T) Relative values of tubes of various shapes.
(U) Influence of location.
(V) Problems involving advancing and retarding ignition.
(W) Influence of changes in the fuel ratio.
(X) Influence of time, involving speed of the piston.
(Y) Volumetric efficiency changes due to heat.
(Z) Advantages of efficient cooling.

Thermal Capacity of Substances—The thermal capacity of any body is the quantity of heat required to raise a unit of the mass 1 degree on a thermometer which registers sensible temperature. Water is taken as the standard of comparison, and when one pound of water is heated one degree Fahr. the energy expended in the process is said to equal one British thermal unit (abbreviated B.T.U.). The several heat units used are:

(a) British thermal unit (B.T.U.).
(b) French thermal unit (F.T.U.) or calorie).
(c) Pound-calorie unit (P.C.U.).

For convenience the values of the respective units may be resolved as follows.

B.T.U. = P F.
F.T.U. = Kg C.
P.C.U. = P C.

The last named unit is but little used, although it represents a certain utility in practice when the centigrade scale is used.

When P = weight of substance in pounds.
Kg = weight of substance in kilograms.
F = temperature in degrees Fahrenheit.
C = temperature in degrees centigrade.

Equivalents of thermal units may be determined as follows:

F.T.U. = B.T.U. × 3.968.
B.T.U. = F.T.U. × 0.252.
P.C.U. = B.T.U. × 1.8, or F.T.U. × 0.4536.

Mechanical Equivalent of Heat—Since heat is a form of energy it may be resolved into other units, and Joule's equivalent (mechanical) of heat as determined by him, between 1843 and 1850, was stated as 772 foot-pounds: that is to say, one B.T.U. represents enough energy which, when expended mechanically, will raise 772 pounds one foot in one minute. Professor Rowland, in 1880 (*Proc. Acd. Arts and Sciences*), proclaimed that a difference was found and his determination of the mechancal equivalent of heat was probably nearer to 778 foot-pounds than 772 as fixed by Joule.

It is sometimes convenient to reduce heat to electrical units, which may be done as follows:

$$\text{F.T.U.} = I^2Rt \times 0.24, \text{ and } t = \frac{\text{F.T.U.}}{I^2R} \times 0.24,$$

when,

I^2 = square of current in amperes.
R = resistance of the circuit in ohms.
t = time in seconds.

As a matter of fact it is easier to handle all of these computations, using electrical notation, which to do requires a certain familiarity with the methods in vogue. In the absence of this knowledge it will be necessary to proceed in the customary way, and with the constants as here afforded it should be a sufficiently easy matter to proceed without the other method.

Specific Heat Variations—Water is not of the same density at all temperatures, and since the specific heat is measured in terms of mass and temperature, it follows that a correction must be made for volumetric changes due to temperature when great accuracy is desired. The temperature of maximum density of water is 39.1 deg. Fahrenheit, or about 4 deg. Centigrade. In ascertaining the equivalents of temperature in the several standards it is convenient to proceed as follows:

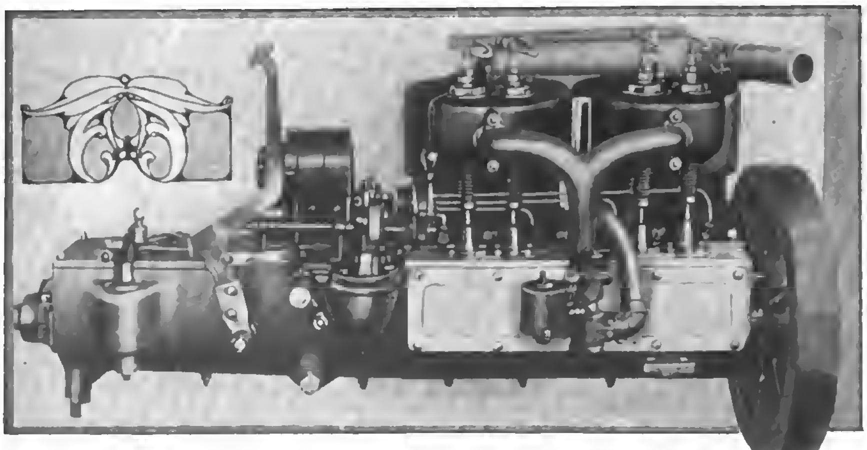


Fig. 1—Thermo-syphon system of cooling as used on the Maxwell Model Q motor for 1910

Extracts from Vol. I., Part V., Chapter II., of a set of books, in preparation, by Thos. J. Fay, covering all phases of automobiling, from the point of view of designers, and in actual service.

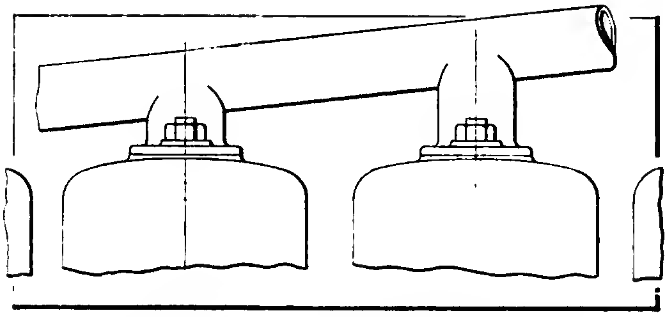

Fig. 2—Rigid water manifold above cylinders

Let F = temperature in degrees Fahrenheit.
C = temperature in degrees Centigrade.
R = temperature in degrees Reaumur.

$$\text{when, } F = \frac{9 \times C}{5} + 32, \text{ or } \frac{9 \times R}{4} + 32$$

$$C = \frac{5\,(F - 32)}{9} \text{ and } R = \frac{4\,(F - 32)}{9}$$

As an numerical example of the use of the formulae let it be granted that the temperature of maximum density of water is 39.1 deg. Fahrenheit, and to reduce this to degrees centigrade proceed thus:

$$C = \frac{5\,(F - 32)}{9} = \frac{5\,(39.1 - 32)}{9} = 4 \text{ nearly.}$$

Saline solutions, as sodium chloride, calcium chloride, alcohol and water, glycerine solutions, etc., will not have the same thermal capacity as water, the actual thermal capacity of the solution to be used in cooling must be considered, especially as water is the more competent solution, so that, if the ability of the circulating system is limited, the cooling medium may be below the requirements in point of quantity circulated, unless the circulating pump is speeded up or some equivalent method is employed. To illustrate the point it is only necessary to set down some thermal values of saline solutions alongside of water, as follows:

SOLUTIONS	SPECIFIC HEAT
Water	1.
Sodium chloride (20 per cent)	0.829
Calcium chloride (20 per cent)	0.834

If a cooling system is so closely designed that the water will steam under the conditions of its use, it is certain that saline solutions will give trouble, in view of the above, since the quantity of "brine" circulated will be no more and the thermal capacity of the same is less than water.

Just as the thermal capacity of the cooling solution is a factor, when the ability of the same is being measured, so must the thermal capacity of the air used for cooling be considered in any attempt to ascertain the weight of air required for the purpose.

Specific Heat of Air—The specific heat of air, according to Regnault, has mean values as follows:

Between —30 and +10 deg. C. specific heat = 0.23771.

Between 0 and 100 deg. C. specific heat = 0.23741.

Between 0 and 200 deg. C. specific heat = 0.23751.

The specific heat of air at a constant volume differs from the

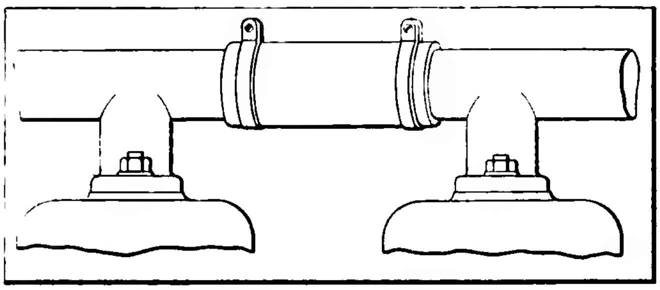

Fig. 3—Flexible connection in water manifold

above, and, according to Professor Woods, the value which will most nearly represent the same may be found as follows:

$$\text{Specific heat at a constant volume} = \frac{\text{mean specific heat}}{1.406}$$

The value, at a contstant volume, is usually taken to be 0.1689.

In cooling work, it is of some importance to note the manner of the use of air, and if it is at a constant volume, the ability will be much reduced, as the above values indicate.

Effect of Heat on Volume of Air—When the cooling air strikes a heated wall, the heat is communicated to the cooler air, and the volume of the air is increased in consequence. The coefficient of expansion of air is given as follows:

In the centigrade scale, at a constant pressure, the coefficient of expansion, per degree centigrade, is equal to;

$$\frac{1}{273} = 0.003665,$$ in which 273 represents the absolute zero on the centigrade scale.

In the Fahrenheit scale: at a constant pressure, the coefficient of expansion, per degree Fahrenheit, is equal to:

$$\frac{1}{491.2} = 0.002036,$$ in which 491.2 represents the absolute zero in the Fahrenheit scale.

Absolute Temperature Measurements—The melting point office is represented by:

0 degrees centigrade; 0 degrees Reaumur, and 32 degrees Fahrenheit.

Absolute temperature, unlike the degrees on thermometer scales, which deal with sensible measurements in common practice, as above depicted, date to the point at which an imaginary gaseous medium would be without volume. Absolute temperatures may be measured in degrees centigrade, Fahrenheit, etc., in which the following will hold:

On the Fahrenheit scale: 32 degrees Fahrenheit = 491.2 degrees absolute.

On the centigrade scale: 0 degrees centigrade = 273 degrees centigrade.

With the above considerations as a basis, computations, involving air, may be made as follows:

One cubic foot of free dry air, at the sea level, weighs 0.080728 pounds, and the volume of one pound:

$$v_o = \frac{1}{0.080728} = 12.837 \text{ cubic feet.}$$

Since, under the conditions named, the pressure of the air is equal to 2,116.2 pounds per square foot, (14.682 pounds per square inch) the following will hold:

$$\frac{p_o\,v_o}{T_o} = \frac{2{,}116.2 \times 12.387}{491.13} = 53.37 = \frac{p_o v_o}{T_o} \text{ and}$$

$pv = 53.37 \times T_o$ as arrived at by Prof. Woods, when,

p_o = pressure due to a temperature of 32 degrees Fahrenheit.

v_o = volume of the gas at the same temperature.

T_o, p and v being the temperature, pressure and volume at any other temperature; T being absolute temperature, at the melting point of ice.

The Latent Heat of Fusion and Evaporation—It is generally considered that the latent heat of fusion does not come into play when reference is had to cooling problems, and this is true, unless account is taken of the performance of excesses of salts, in a saline bath, as calcium chloride. Fusion, in the sense that a solid is liquified, takes place when salts are dissolved, and amonia chloride, for illustration, is a decided refrigerant under such conditions. The ability of solvents is limited, and when the amount of salts which can be dissolved in a liquid, as water, is up to a certain point depending upon the salts and the liquid, the solution is said to be saturated.

A state of saturation is dependent upon temperature to quite some extent, and as the temperature is increased the saturation limit increases also; in other words, if the liquid is heated, the amount of salt which can be dissolved will be increased. It follows, when dealing with saline solutions in a state of near saturation, that some of the salt will precipitate, when the temperature is lowered, only to dissolve again when the temperature is increased: under such conditions the latent heat of fusion would come into play, and there are conditions under which this principle might be of value in cooling work.

The latent heat of evaporation is of the greatest importance, and when water, in the cooler, reaches the boiling point, it is because of this latent heat that the water does not quickly boil away. Water boils at 212 degrees Fahrenheit at the sea level, and if the water enters the radiator at 100 degrees Fahrenheit, the thermal value of one pound of the same, between the entering temperature and the boiling point will be $212 - 100 = 112$ B.T.U. (approximately). When one pound of water is boiled, under a pressure of one atmosphere (14.7 pounds per square inch) the latent heat of boiling is 965.7 B.T.U. From this, it will be observed that one pound of water, if it is turned into steam, in a cooler, if the same is opened to the atmosphere, which is always true, will require the expenditure of nearly ten times as many heat units as will be taken up in raising the temperature of the water from 100 degrees F. to the boiling point.

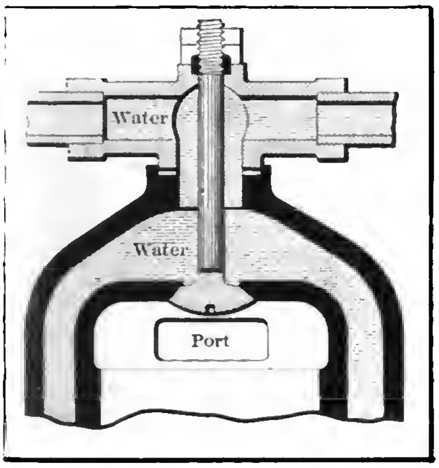

Fig. 4—Showing water connection above cylinder and a liberal body of water

The effect of altitude will be present, since water boils in a vacuum at a lower temperature than it does at the atmospheric. The approximate effect of altitude on the boiling point of water in the radiator, may be stated as follows, remembering that increasing altitude has the effect of rarefying the air just as it is reduced in weight for volume in a vacuum, and in a vacuum water boils at a lower temperature than it does at sea-level pressure.

BOILING POINT OF WATER AT VARIOUS ALTITUDES

Altitude Above Sea Level in Feet	Boiling Point of Water in Degrees Fahrenheit
Sea level	212
1,025	210
2,063	208
3,115	206
4,169	204
5,225	202
6,304	200
7,381	198
8,431	196
9,579	194
10,685	192

It is considered good practice to run the temperature of the water in the radiator at about 202 degrees Fahrenheit, under normal conditions, which allows a margain under adverse conditions, as on a long steep grade, and when cars at the "curb," running the motor free, on a retarded spark. These radiators would steam where the cars are running under normal conditions at an altitude of about one mile. In cases involving steaming radiators under normal conditions, at the sea level, mountain climbing becomes quite out of the question.

Internal Surfaces of Cylinders—The prime object in cooling is to maintain the temperature of the metal of which the cylinders are made, below the point that will produce lubricating trouble, preignition and pronounced rarefaction of the incoming charge. Were the cylinders made of a material such as would not absorb heat, there would be no occasion for cooling, and the principle of limiting surface exposed to the hot products of combustion, on the inside of the cylinders, has the virtue of reducing the cooling requirement without interfering, in any way, with the functions of the motor, and with a gain represented by reduced cooling trouble.

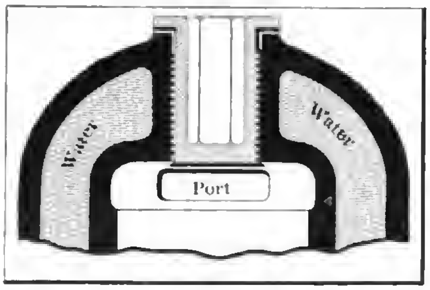

Fig. 5—Liberal body of water above dome of cylinder with side connection

It is common practice to extend the water-jacket, of cylinders, to a point just below the bottom of the stroke, measuring at the top of the piston. Watering below this point would add weight and complication, without delivering an equivalent advantage. The combustion chamber space begins at the top of the piston, at the top of the stroke, and the major portion of the heat must be tapped away through the surface thus exposed, although it is true that overheating would be eminent were the water-jacket stopped off at the top of the stroke rather than at the bottom.

Since all cylinders are round to a point well above the top of the piston, on the top of the stroke, none will differ overmuch as respects the internal surface, up to a point near the fillet of the dome; beyond this point there are wider differences in the several designs, partly due to differences in shapes of domes, but mostly on account of the location of valves, and differences in surfaces of valve-ports. Considering domes only, it is to be expected that a half sphere will offer the least internal surface, since, for a hemisphere, surface for volume is a minimum. Through the use of the formula as given below, it will be found that flat heads offer the greatest surface, and hemispherical domes the least; modifications of both will resolve into areas between the two limits, and when valves are not in the head, it will be necessary to ascertain the increase in area due to port-walls, as an especial effort in each example, since no two designs will be alike, nor can any rule be established which will be general in application.

In considering this phase of the cooling problem, it is a simple matter to assume that surface (internal) is the "valve" which allows the escape of heat, and limiting the surface, limits the escape of heat. This very idea carries with it the logical conclusion that, the greater the effective external surface, in proportion to the internal surface, the cooler will the metal of the cylinders become, and the better will cylinders perform in service, under adverse conditions.

Surfaces May Be Resolved for Comparison—

Let,

d = diameter of cylinder bore.

l = length of cylinder between the top of the piston at the top of the stroke and the point of beginning of the hemispherical dome.

A = area of internal surface of combustion chamber.

a' = area of flat dome not counting area of side walls.

a'' = area of hemispherical dome not counting area of side walls.

a''' = area of side walls neglecting area of walls of valve-ports when valves

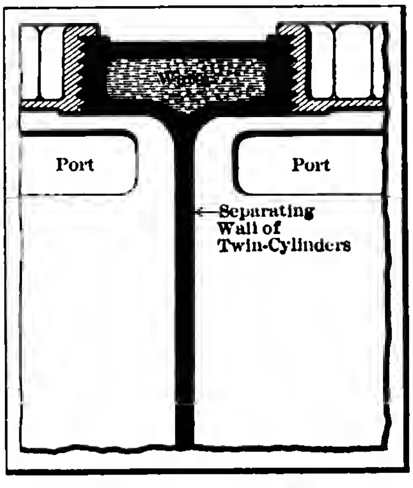

Fig. 6—Common wall for twin cylinders which defeats equal cooling to some considerable extent

are in the head as in some types of cars, mostly for racing.

For hemispherical head types, not counting errors due to shapes of valves in the head:

$$a'' = \frac{\pi d^2}{2}$$

$$a''' = \pi d l$$

$$A = a'' + a'''$$

For flat heads, neglecting irregularities due to shapes of valves, considering types with valves in head:

$$a' = d^2 \frac{\pi}{4}$$

$$a''' = \pi d l$$

$$A = a' + a'''$$

The magnitude of a''' will not be the same when the dome is a hemisphere as it will in flat-head cylinders, since some of the combustion space will be within the dome of the hemispherical contour, which will not be true when the head is flat.

Best Thickness of Cylinder Walls—From the point of view of cooling, which is a matter separate from the strength required to resist pressure, the best thickness of walls to establish, will be the least possible. If internal surface is restricted, thus serving as a valve, limiting the amount of heat which can pass through, the coolest condition of the metal will follow under the conditions as follows:

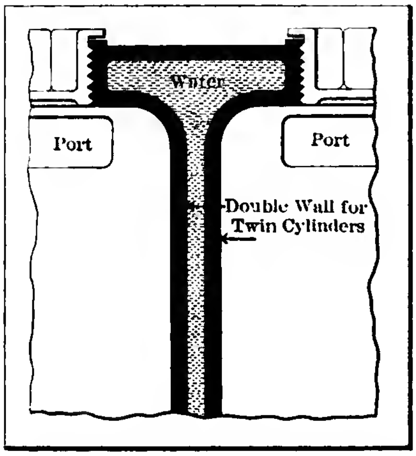

Fig. 7—Separate walls, with a water space between, rendering cooling uniform

(A) With the greatest possible effective external surface.

(B) With the maximum difference in temperature between the metal in the external surface and the cooling medium.

(C) If the walls are thin, since the distance heat will have to travel in the metal will then be minimum.

(D) When the cooling medium is circulated at a sufficiently rapid rate to maintain the greatest possible difference in temperature.

(E) With a cooling medium of the maximum specific heat, highest boiling point, lowest internal heat resistance, best conditions of conduction, and the best conditions of convection, which is a property depending upon the relative motion of the molecular structure of the fluid, which is augmented properly regulated circulation.

That the walls should be thin, is shown by consulting the law of internal conduction, as follows:

"For a given heat conductivity of the material used, internal conduction is directly proportional to the difference in temperature and inversely proportional to the thickness of the wall." This same law indicates, in no uncertain way, that the cooling medium should be a thin layer circulated over a large surface, beyond a certain speed, it will be of small avail to circulate the liquid, for, when the speed is so great that the molecules of the liquid will fail to absorb sufficient heat, which property is retarded by limiting conduction, the circulating effort is excessive, and power will be saved by lowering the rate of circulation of the liquid.

The lower the rate of circulation of the liquid, the thicker should be the layer of cooling liquid over the surface, and in the thermo-syphon system of cooling for illustration, this idea is reduced to a logical conclusion. The thermo-syphon principle of cooling is depicted in Fig. 1 of the Maxwell Type Q motor, which is a 1910 product. Referring to the illustration, and the water connections at the top of the cylinders, it will be noticed that the piping is tapered towards the radiator, at the front, and in order to take full advantage of the principle, the area of the piping is made very liberal. In this system, instead of circulating the water by means of a pump, the whole jacket system is submerged in water, due to the elevation of the radiator, and there is a natural exchange of cold for hot water going on all the time.

Weight of Water at Different Temperatures—Rankine gives, for the weight of water at its point of maximum density, 62.425 pounds per cubic foot. At the boiling point, the weight is less, by 2.77 pounds per cubic foot, which is a mean average of values as given by several authorities. At 62 degrees Fahrenheit, the weight is generally taken to be 62.355 pounds per cubic foot.

In view of the positive difference in weight, between hot and cold water, and since the phenomena of segregation assures that the heavier liquid will migrate to the lower level, this method of cooling possesses the virtue of affording a uniform temperature over the surfaces to be cooled, and a relatively slow but dependable method of circulating the water, thus bringing the cooling influence of the radiator to bear, and while it is necessary to use a radiator of adequate area, it is unattended by such complication as a pump must necessarily involve.

Some Minor Details to Consider—Besides having the piping of adequate area, it is necessary to assure that one cylinder will not rob the other of its share of the cooling fluid, and it is also desirable to maintain tightness of the joints of the piping, which may be done, either by properly contrived manifolds, without flexible joints, as shown in Fig. 2, or, with hose joints, as depicted in Fig. 3. At all events it is desirable to have a substantial body of water above the dome of the cylinders examples of which are offered in Fig. 4 and 5, with the understanding that the methods of sealing the cylinders, shown, are not here under discussion, nor do they represent the most approved ways.

Fig. 6 shows a dividing wall between cylinders, which is common for both, and that a certain amount of unequal expansion will result from this plan, is a common claim, yet even so, a vast number of motors have been put out in this way, and it has not been indicated that any serious ill resulted. Fig. 7 depicts the plan that represents freedom from unequal expansion, and when room is not at a premium, it is well on the side of safety.

Conductivity of Metal of Cylinder Walls—When cylinders are finished all over, as they are in the examples involving the use of copper jackets, the conductivity of the metal is that of cast gray iron, when cylinders are so made, but in most cases the walls are not finished on the exterior, and the conductivity is that of the iron hampered by a skin, which detracts from the heat-conducting ability to a very considerable extent.

That this skin will act quite as badly as a crust is generally well understood, and as for incrustation, there is bound to be a certain amount of it after a motor has performed in service for a certain length of time. The nature and hardness of the scale will depend upon the substances held in solution in the cooling liquid and to a vast extent upon the amount of boiling that takes place. If the cooling system does not waste water, it is then possible to consider that the amount of scale which will form will be limited to that in the small amount of water likely to be used.

It is estimated that a scale to a depth of 1-16 inch will diminish the conductivity by 13 per cent., while a coat 1-4 inch in depth over the surfaces will diminish the conductivity 38 per cent. That this is at the bottom of some of the troubles experienced with high compression motors is one of the matters to be relied upon, and even if the scale is not baked on it will have substantially the same effect. In certain parts of the country, notably in the vicinity of the Great Lakes, this question of scale (deposits) is uppermost.

(To be continued)

Grease or Oil in Transmission Gears?

By H · L · Towle

WITHOUT a doubt the duty imposed on the transmission gears of an automobile, including the bevel gears, is more …ere in proportion to the size of the gears than that encoun…ered in any other class of machinery. The steels used for these …ars are among the strongest and toughest known in order to …sist breakage, and the toothed faces are brought to a file-like …ardness to resist wear. The pressures per square inch between …e teeth are greater than those of almost any other bearing sur…es, and in spite of their hardness wear is more rapid than …uld be considered permissible in bearing surfaces of other …sses. As it is only the lubricant which prevents these gears …m reducing each other to a powder in a short time, the char…er of the lubricant is a matter of considerable importance.

…f there were no other consideration involved one might say …hout hesitation that a fairly heavy grease would most effec…ely protect the gears from wear. Undoubtedly where grease …n be used it is the most suitable lubricant. Nevertheless, it is … most cases necessary to consider not merely the gears, but …e bearings as well, as usually these depend on the same lubri…nt as the gears. The selection of a lubricant is therefore fre…ently a compromise between conflicting interests.

…f the bearings of the gear case are anti-friction throughout—…ter yet, if they are not only anti-friction, but separately in…sed and packed with vaseline—one may safely treat the gear …ication on its own merits, and the choice will probably fall … a grease of medium consistency with a moderate amount of …ng." The purpose of the cling is to prevent the gears from …ing a path in the grease and therefore turning in empty space. … the other hand, in some transmission greases observed the …g is excessive, and the drag due to the churning action cannot … being considerable. If the grease is just soft enough so … it will not quite hold its shape it will continually settle to … bottom of the case and keep the gears supplied. It is not …essary that the case should be filled to the level of the shaft, … only that the smallest gear should dip an inch or so into … grease.

…orm of Bearings Influences Lubrication—All this assumes … there is not a plain bearing anywhere in the gear case. In …y otherwise anti-friction transmissions, however, there are … plain bearings. One is the reversing pinion bearing, and the …er is the bearing by which the squared shaft enters the main …ing pinion. As the reverse gear is seldom used, and then … for a few moments (unless one breaks the first speed and … to back up hill), the present writer is not prepared to affirm … a plain bearing at this point prohibits the use of grease. …lly this bearing is supplied through one or two holes drilled … the pinion at the base of … teeth, so that oil or grease … forced in when the pinion is … mesh. It is fair to suppose … grease may be used if … holes are not too small. … other bearing, however—…de the main driving pinion …ust be well lubricated be…d peradventure, and if it is … the plain bushed type, the …al one or two one-eighth …h holes drilled at the base of … pinion teeth are far from …ficient to induce grease to …ter in sufficient quantities. … plain bearing at this point, …erefore, definitely debars grease. In many recent cars, this fact is recognized and anti-friction bearings are employed. Fig. 1 is an example. The shaft *A* is connected to the clutch, and shaft *B* carries the forward universal joint of the propeller shaft. The end *C* of shaft *B* turns in a bearing of long rollers of small diameter inside the main driving pinion *D*, which is formed on an enlarged portion of shaft *A*. *A* runs in a taper roller bearing, and is steadied against possible rocking by shaft *C*. In other constructions a pair of annular bearings is used between *C* and *D* in place of the roller bearing, Fig. 1.

In case grease cannot be used in a gear case, the usual alternative is gear case oil, which is a low-priced grade of steam cylinder oil to which tallow has been added to give it as much body as is consistent with ability to flow. It is not a bad plan to add a small quantity of graphite to gear case oil, as experience seems to show that the graphite prolongs the life of plain gear shaft bearings considerably by giving them a glaze which helps them to resist the cutting action of small particles of steel worn off from the gears and floating in the oil. Caution must, however, be used not to add too much graphite. About one-half teaspoonful to the quart is sufficient. An excess is liable to clog the bearings or oil grooves.

Jack Frost Calls for Oil—In cold weather it is sometimes necessary to thin gear case oil to counteract its tendency to thicken by degrees after it is put in. Unless the oil will flow, it is worse than grease. A suitable quantity of cheap machinery oil or even kerosene may be used as a thinner.

Allusion was made just above to the grit worn from the gear teeth. This grit is a factor demanding serious recognition, as it is impossible to prevent the gears from wearing at a rate which even at the slowest would be considered quite inadmissible in ordinary shaft bearings. The steel powder thus ground away is more or less supplemented by actual pieces or fragments knocked off when the gears are shifted, and forms an abrasive which would be admirable if it could be applied to a useful purpose. It seems impossible to prevent this grit from entering the bearings to some extent. Attempts were made in cars of a few years ago to oil the gear shaft bearings (which were plain bushed) by separate oil pockets with oil rings or chains. The results were unsatisfactory, as it was difficult to keep the oil pockets filled and the grit-laden oil from the gears persisted in working along the shafts into the oil pockets, cutting the bushings as it did so. The attempt to use grease in the shaft bearings would probably have been successful if the owners of the cars could have been persuaded to keep the grease cups filled, but their neglect to do this necessitated a hunt for a more nearly automatic system. It seems impracticable to use oil so thin that the grit will settle (except the heaviest chips), and the best alternative appears to be using grease, if possible, for its protective effect on the gear teeth, and using bearings of such form as permits grease lubrication. As already stated, any form of good anti-friction bearing falls in this class, although it may be surmised that ball bearings are better than roller bearings, owing to the chance they give small solid particles in the oil to squeeze out instead of being crushed

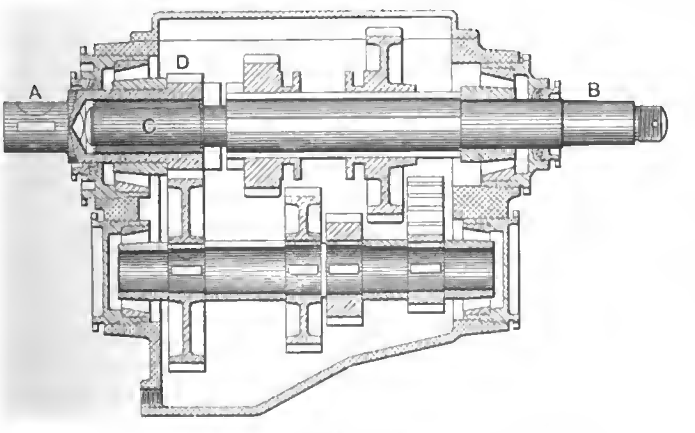

Fig. 1—Typical transmission with roller bearings

between the rolling surfaces. If the principal ball bearings could be enclosed in boxes and packed with vaseline, they might be deemed to be protected as thoroughly as possible, and a few builders of the more expensive cars have gone to this expense, although it must be said that most of them leave the inner faces of the bearings open to the grease from the gears.

Consider the Differential, It Toils Not But Spins Continuously—Let us now consider the bevel gears and the differential. One might be disposed to assert off-hand that these should be packed with grease. However, we are again confronted, as regards the differential at least, with the presence of plain bearings which, if small, are still important. Grease is an ideal lubricant for work of this class *provided* it can be forced to the bearing surfaces either by pressure or by the relative movement of the parts. Bearings fed by compression cups fulfill the first requirement; the majority of universal joints and grease-packed steering gears fulfill the second. But in the bearings of the small differential pinions we have a situation which offers grease of ordinary stiffness small chance to be effective. Figs. 2 and 3 show two typical differentials. The shell *A* has openings of sufficient size to admit grease freely to the bevel gears and pinions within. The pinions run on arms of the spider *B* and have oil holes *C C* drilled at the base of the teeth. The whole arrangement is rotating more or less rapidly, and the tendency of centrifugal force is outward. Of course, some grease or oil will enter the shell in spite of the centrifugal force, but is it not certain that the rolling action of the teeth will force enough grease through the oil holes *C C* if the grease is stiff. It may almost be declared to be the exception rather than the rule to take the differential apart and find the pinion bearings in even moderately good condition. They are usually "cut to pieces," and the thrust washers back of the pinions are not much better off. It is hard to propose a more effectual way of feeding lubricant to these small bearings than by way of the holes *C C*, but in view of this fact it seems clear that oil—as heavy as may be depended on to flow—is the more suitable lubricant.

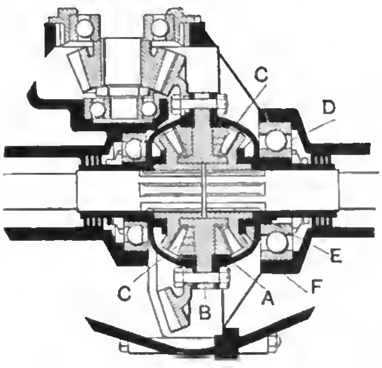

Fig. 2—Differential on ball bearings

In most modern cars, ball bearings *D* are interposed between the sleeves *E* and the stationary housing *F*. In many of the older, and not a few of the modern cars, however, plain bearings are used at this point. This is particularly apt to be the case in chain-driven cars, in which the differential is in the gear box, and the sleeves *E* are extended to a considerable length on each side, one or both carrying brake drums outside the gear box. It is conceivable (though hardly probable) that if grease be used here the external bearings of the sleeves *E* in the stationary bushings will be properly lubricated without special provision being made. But how about the shaft bearings inside these sleeves? The shafts turn relatively to the sleeves whenever the differential is working—and in practice, if not in theory, the differential is working more or less most of the time. If one hunts, he will usually find one or two oil holes hidden away somewhere near the inner ends of the sleeves *E* by which oil is supposed to enter and lubricate the shaft. But any repair man can tell of cut bushings and shafts needing to be reground on account of refusal of the oil to disobey the law of centrifugal force and work in through those holes instead of out. If reasonably fluid oil is used the shafts have at least a chance, but if grease is used they have no chance at all.

Grease That Is Grease—It is, of course, understood that where the word "grease" has been used above, a stiff body is meant —in other words, grease that really is grease. Quite possibly it is the recognition of the limitations of grease in such cases as those cited above that has led the manufacturers of certain greases to add to their product so-called greases which are in reality heavy oils, and are sufficiently fluid to feed by capillarity rather than by pressure. As these products are doubtless called grease for trade purposes, no quarrel need be raised with the name. The important thing to be remembered is that where pressure in one form or another—from a compression cup or from motion of the parts themselves—is available, grease is more suitable than oil; but where no such feeding force is at hand, the lubricant must be sufficiently fluid to feed itself by gravity and capillary action. This, of course, refers to plain bearings only.

To sum up, grease is abstractly preferable for gear lubrication to oil, and is to be preferred wherever the gear lubrication is not complicated with questions of plain bearing lubrication. If there are plain bearings to be lubricated by the same unguent that lubricates the gears, oil is almost invariably essential.

Whether grease or oil be used, it must be renewed occasionally when an examination discloses gritty particles floating in it. A simple way to test the oil is to dissolve a spoonful of it in a tumbler of gasoline and strain it through a cloth, when any suspected metal particles will easily be found.

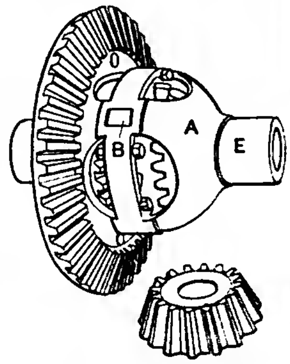

Fig. 3—Spider allows grease to pass

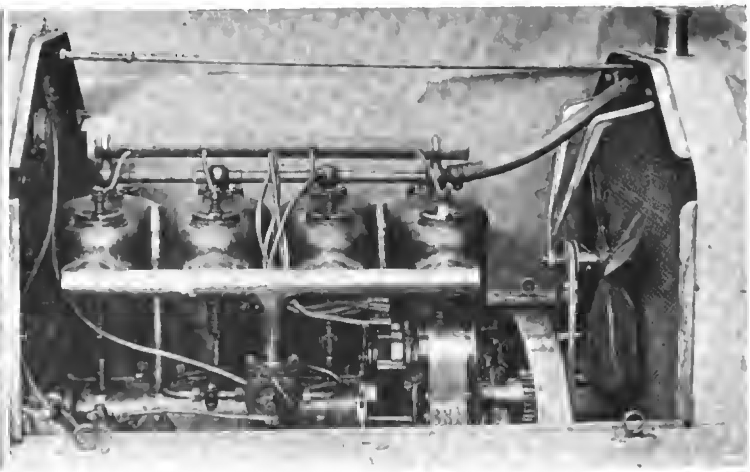
In closing, it should be said that the above remarks apply only to mineral greases. Greases compounded of animal fats have not been considered at all, since while they have their uses, they are distinctly unsuitable for gear lubrication, because of the fact that they remain hard until softened by heat—which heat must generally be engendered by the friction of the rubbing parts themselves. In addition, animal greases are not permanent. They turn rancid in time and form acids very deleterious to bearing surfaces. Where ball or roller bearings are used, grease containing any percentage of animal fats should be absolutely excluded.

FLAME TEMPERATURE OF BURNING GAS

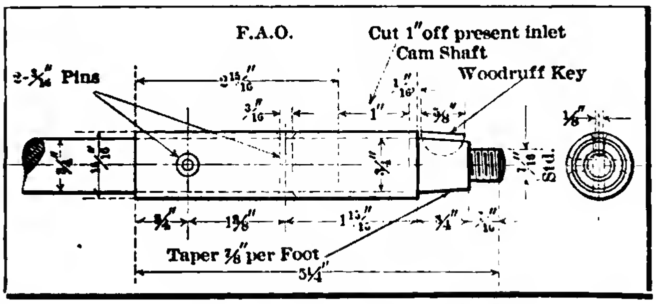
Calorific value of a combustible, as gas made from air more or less saturated with a hydrocarbon, as gasoline, is not all to take into account when reference is had to the intensity of heat, referring, of course, to the sensible temperature. Take, for illustration, hydrogen; a much hotter flame will result if the hydrogen is burned in the presence of pure oxygen than will follow if the oxygen is conveyed into the cylinder with nitrogen, as in air. The number of heat units will be the same in the hydrogen in both cases, but when the air is considered, account must be taken of the nitrogen content, which, it will be remembered, represents 3.35 parts. This nitrogen represents nothing by way of calorific in itself, and it has to be heated at the expense of the heat units in the hydrogen. Since the specific heat of nitrogen is 0.24 (approximately) the large nitrogen content has a marked effect upon the sensible temperature of the burning gas. Likewise, "spent" products of combustion, left over from the previous charge, will reduce the temperature of the burning gas, and even the hydrogen itself has to be heated, and the net result is a lowering of temperature. These events might be looked upon in the light of an unmixed evil, but account must be taken of the heat that would pass off to the water-jacket in excess of that which now passes off that way were the sensible temperature increased, as it would be in the absence of the very nitrogen to which allusion is here made. In view of all the influences, the right plan is to strike a happy medium, rather with the expectation that, on the whole, the best results will follow if no one point is accentuated at the expense of the other and equally important details.

How I fitted a Magneto to a Small Runabout

By Joseph Tracy.



IT is to be remembered that I have always been an advocate of magneto ignition, not alone on the racing cars that I have driven, but also on all kinds of touring cars, so when I became possessed of a Model "S" Buick which was fitted with battery ignition I at once became obsessed with the idea of converting it into a car having magneto ignition only. My Model "S" Buick is a runabout, carrying two people, and the motor is of the 4-cylinder type, developing 24 hp. I use it largely in the streets of New York for business purposes, in the vicinage of Automobile Row. The car, which is one of the first of this model produced



Sketch of Necessary Machining on Camshaft

by the Buick Company, has had steady and strenuous service, but now that I have changed it from battery ignition to an up-to-date magneto system I feel that others might be interested in the way in which I did it, and hence this story and the copies herewith of the six mechanical drawings showing the change, accompanied by a photograph of the right side of the motor.

Now, there are three systems of high-tension magneto ignition in vogue—the single system, the magneto alone, as the sole source of current supply; the dual system, which embraces the magneto and the battery system combined through one set of plugs, wires and a switch, and which really might be called a system and a half, but in a mechanical sense rather than in a derogatory sense. The third and last system is the double system, which embraces two complete systems, a double set of plugs, a double set of wiring, a magneto and a battery, so that either can be switched on at will, as in the dual system. I decided to install a simple, single system, and finally selected the U. & H. Master Magneto of the C B 4 type for the alteration.

This magneto is of the true high-tension type, and no coil is necessary for its operation. It not only furnishes the high-tension current, but times and distributes it so that the spark occurs in the proper cylinder at precisely the right time in relation to the piston travel. Thus the entire ignition apparatus necessary to operate the motor consists of simply the magneto and the spark plugs in their respective cylinders.

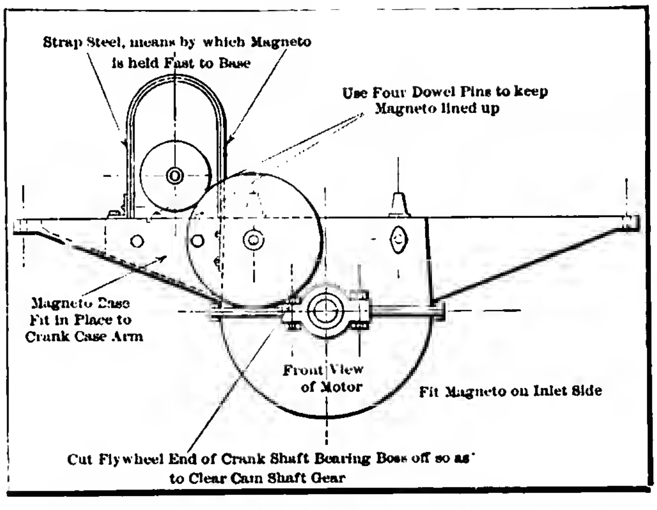
The spark delivered by this magneto is entirely different in its character from the spark produced either by battery and coil systems or by magnetos which employ a separate coil to transform (or step up) the low-tension current they generate. It is not a mere spark leaping across the gap of the spark plug, but an actual arc flame, which plays across the gap for an appreciable length of time.

The principles upon which this magneto operates are not new, having been in use for a number of years, in which time the superior igniting qualities of the spark and the absolute reliability of the system have been thoroughly demonstrated.

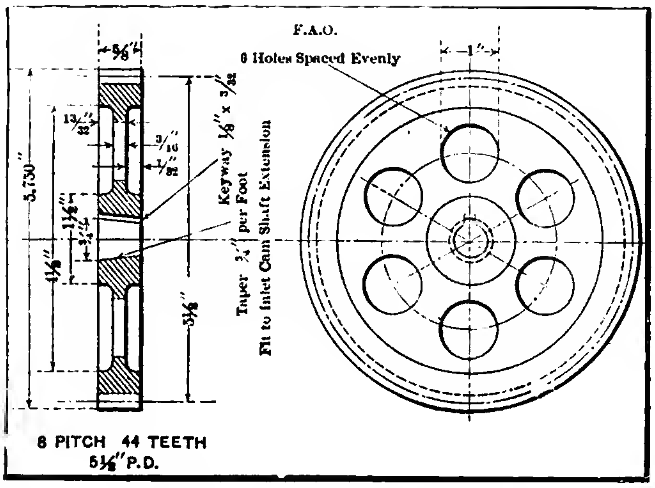
The photograph shows the method of wiring, which consists only of one wire for each cylinder leading from the magneto directly to the spark plug, and a single wire leading from the magneto to the switch on the dash, the four wires being first carried in a hard, red fiber busbar, as shown, on the top of the motor, and from there branching out to each separate sparking plug.

For the detailed plans of the alteration I refer the reader to the six clear reproductions of the original drawings shown herewith, because, in the language of the specifications of the Patent Office, to those familiar with the art they will be readily understandable, and any good mechanic who can read a drawing should be able to thoroughly understand them.

In looking the car over before commencing to make notes for the drawings, I found that the only alterations to be made would be on the right-hand side of the motor. Here the main feature in the way of placing the magneto was the shape of the curved gas inlet manifold. I removed this and replaced it with a perfectly horizontal one, as shown in the photograph. Having no further use for the battery, which was carried under the rear turtle deck, I removed that also. The coil was removed from the dash, and as the magneto carries its own timer internally, I removed the timer and covered up the shaft hole in the crank case with a plate cover, bolted on, as shown in one of the draw-



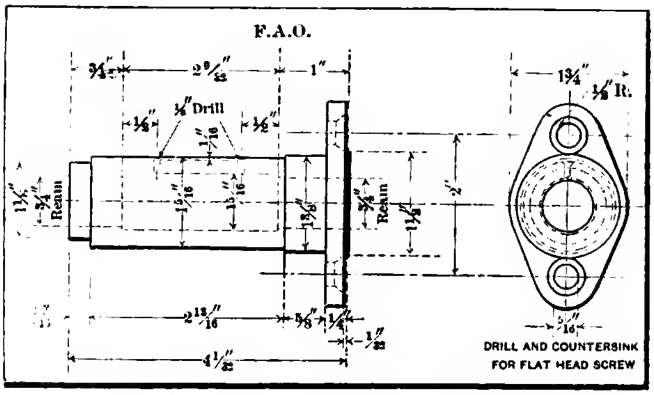
Drawing to Show General Scheme of Magneto Fitting



Detail of New Camshaft Gear Required

ings. The extension of the cam shaft which carries the gears to drive the magneto I carried out through a blind hole in the forward end of the crank case, and all that was necessary to do there being to remove the cover of the hole. The bed plate in the arm of the crank case, on which the magneto rests, I made of bronze, and after having everything fitted I found that it was as easy—a quarter turn sufficing—to crank off the motor on the magneto as it was previously on the battery, and that has been my experience ever since.

In order to prevent "joy" riding on my car in my absence, I fitted a little Yale lock on the dash, which locks the bonnet in place so that it cannot be opened; it also cuts out the ignition service, and, as I have the only key for the lock, the car cannot



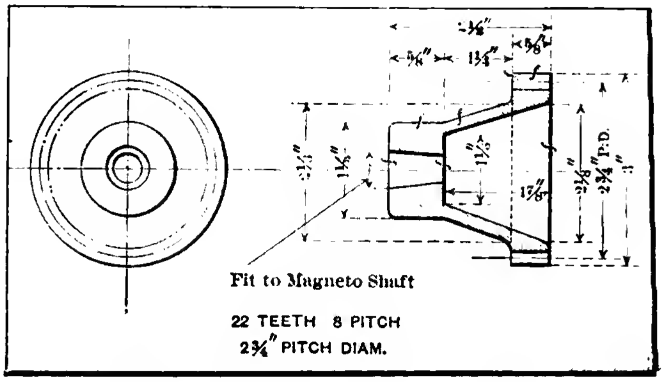
A Flanged Driving Sleeve Is Also Used

be used; and even if this system could be tampered with, I added a French oscillating odometer in a sealed glass case on the dash, which works on the well-known principle of a pedestrian's pedometer, so that the slightest movement of the car will register from the odometer. Beyond all this I did nothing else with the car except to take the steering wheel column a little more toward the rear, giving the car a much more sporty and racy appearance, and placing the steering wheel closer to me, with its gas throttle lever; the spark lever I cut away as useless for fixed ignition. I might further add that a coat of light gray paint which is so fashionable, some black striping and a coat of good varnish have made the little car very presentable, and with its up-to-date ignition system I find it attracts a great deal of atttention, and when the car is standing still and the motor running the magneto driving gears run so quietly and with so little vibration of the bonnet as to deceive many experts along Automobile Row, who doubt very much indeed that the motor is running until a lifting of the bonnet reveals the fact. It also demonstrates to their satisfaction that the U. & H. Magneto is able to produce a good spark when running at an exceedingly slow speed, besides always starting on a quarter turn without spinning the motor.

Any good mechanic can follow out my lines and plan of operation, and the plan may be adapted to use it on many makes of cars where it is desired to change from battery to magneto ignition, and thus bring the car up to date.

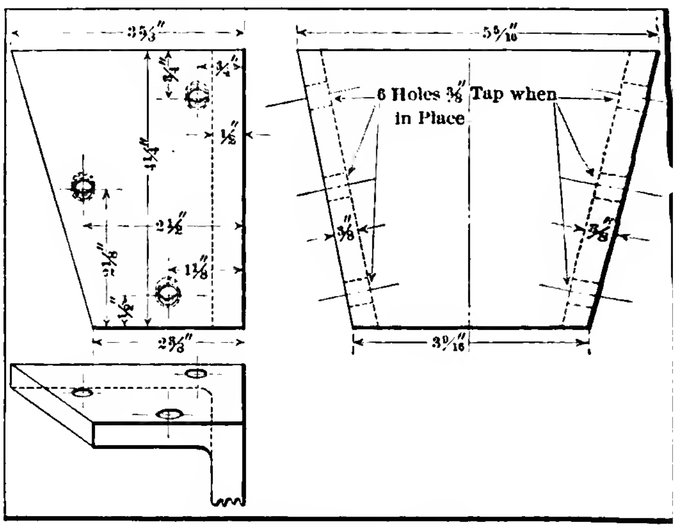
SAFETY IN CONNECTION WITH PRESSURE

Sometimes the exhaust pressure from the motor cylinders as it is led to the gasoline tank is "flaming" and to assure safety it is the custom to pass the exhaust gas to the bottom of the gasoline tank, so that the flame will be quenched in liquid gasoline before the gas is allowed to rise in the tank to the space above the liquid. A further measure for safety consists in placing a copper screen, of close mesh, and two or three layers deep, in the system at the entrance of the gasoline tank, as well as the same kind of a safety device in the reducing valve at the cylinder of the motor. True, the atmosphere in the gasoline tank, as it usually obtains, is non-inflammable, due to the en-



Magneto-Driven Gear Has an Odd Shape

riched condition and the lack of oxygen sufficient to support combustion. On the other hand, it is not considered safe to depend upon the non-explosive characteristics of the atmosphere in the tank, especially in view of the prospect following the time when the gasoline will all be used up, excepting the remaining vapor in the tank, which might then become lean enough to take fire. The screen built on the principle of the "Davy" lamp assures safety if it is of copper, about 120 mesh and about two layers deep, free from seams, and put on without solder which will melt in the heat it will encounter. The tube should be of steel, perforated with small holes.



Bronze Bed Plate for Magneto

AUTOMOBILE SPRINGS AND THEIR CHARACTERISTICS

INVESTIGATION and practice of the members of the Association of Licensed Automobile Manufacturers as to the springs which carry their car bodies and frames make a very interesting tale. Many grades of metal, domestic and foreign, have been used, including chrome nickel steel and steel containing chromium combined with tungsten, vanadium, etc. With special alloy steel, a very superior article can be produced provided the requirements of heat treatment are followed. By some it is advanced that silico-manganese steels will endure longer than high carbon steels. Springs of certain specific analyses are to-day being made which will successfully withstand any test to which they would be subjected.

Typical practice is to have the proper ingredients in the initial product, insisting upon a strict maintenance of this standard when the product is delivered, following with a standardized method of treatment all the way through, including the requirement that the spring will take only so much set under the first test and then stay there. It is necessary to have the furnaces, in which the steel is treated, under pyrometer control, with very slight variation in temperature allowed; and with a so-called "soft" heat, not harsh or severe, as to which the kind of fuel employed is important. The most commonly used heat treatments are annealing, hardening, tempering, hardening and annealing, double annealing, and double hardening and annealing.

It is contended by some producers that a spring with the least arch, that is, the nearest flat, is the safest spring, if enough room for the proper amount of deflection is reserved. This is on the theory that the greater the arch the greater is the fiber strain in a spring.

In connection with front springs, one authority states they should, to preserve proper resiliency, not be thicker than their width; should be fairly stiff, with a maximum deflection of not over one-quarter of an inch per hundred pounds; not off-centered, and have the front eye set higher than the rear eye not less than one-half inch, this latter preventing the car from ducking. That in rear springs, where the problem is relatively easy, the length and width should be as great as possible, if made scientifically as to the spacing of the leaves, the length of the taper and the grading of the steel. There can be made a spring that will take certain dimensions under a given load, and ten thousand other springs which will take the same dimensions under the same load, but it is essential that they have a large number of leaves of special grade steel, specially tempered, with an absolutely correct grading, so that there will be spring play from the center of the eye to the center of the spring, and, too, it is important to have the strains equal in the section of all leaves.

It has long been seen that the carriage spring steel of the last quarter of a century will not do for automobile springs. And successful experiments of the last ten years have given us various satisfactory designs for automobile springs, securing reliability and ease of riding with lower suspension of the body.

The weight, the speed, the traction feature and the variation of passenger load are elements that never until the case of the automobile existed to the same extent in any one vehicle.

QUALITY IN VALVE SPRINGS IN MOTORS

If the valve is light, and if the spring is properly designed and made of good material, it is desirable to have the spring pressure as low as possible, to abort undue pressure on the cams and the mechanism. In many cases the spring pressure is as high as 45 pounds, and that this pressure is prone to cause rapid wear of the mechanism, is assured. If the valve is made as light as the situation would warrant, providing the design is good and good materials are used in the valve, the spring pressure might be reduced by one-half. It must be remembered that springs will not always remain at the same tension, otherwise it would be possible to consider even a lower pressure than the amount above named. The angle through which the camshaft will rotate while the valve is closing is the matter to be noted, which may be done as follows:

Let

θ = angle of camshaft rotation while valve is closing under the action of the spring.

s = speed of camshaft in revolutions per minute.

W = weight of valve in pounds.

P = mean spring pressure in pounds.

l = lift of valve in inches.

Then

$$\theta = \sqrt{\frac{l\,(s \times W)^2\,W}{0.67\,P}}$$

In general the valve should close within an angle of the camshaft rotation of 15 degrees. This will only be possible when the valve is very light, and with well-designed springs. Many springs are very lazy in action, due to improper design, and it is important to note that it is more than a question of size of wire, and number of turns of the same. Diameter of the spring must be considered. Sometimes springs are damaged by heat, due to placing them in contact with heated cylinder walls. To abort this, it is necessary not only to have the springs correct in design, but to limit the lift of the valve, and contour the cams to engender easy action.

PROPORTIONS OF ATMOSPHERIC AIR

(1) To find the quantity of nitrogen by volume corresponding to one volume of oxygen, multiply by 3.77092.

(2) To find the quantity of oxygen by volume corresponding to one volume of nitrogen, multiply by 0.265182.

(3) To find the quantity of nitrogen by weight corresponding to one part by weight of oxygen, multiply by 3.313022.

(4) To find the quantity of oxygen by weight corresponding to one part by weight of nitrogen, multiply by 0.301839.

(5) To find the quantity of nitrogen by volume corresponding to one part by weight of oxygen, multiply by 2.6365411.

(6) To find the quantity of oxygen by volume corresponding to one part by weight of nitrogen, multiply by 0.2730071.

(7) To find the quantity of nitrogen by weight corresponding to one part by volume of oxygen, multiply by 3.6629154.

(8) To find the quantity of oxygen by weight corresponding to one part by volume of nitrogen, multiply by 0.3792848.

Formula for correcting the voluume of gases for temperature and pressure:

$$\frac{V}{V^1} = \frac{(273 + t)\,P^1}{273 + t^1\,P}$$

When,

V = original volume.

V^1 = corrected volume.

t = original temperature in degrees Centigrade.

t^1 = final temperature in degrees Centigrade.

P = original pressure.

P^1 = final pressure.

273 = absolute temperature in degrees Centigrade.

Absolute temperature, if measured in Fahrenheit units, instead of in Centigrade, as above given, would be 491.13 below the melting point of ice. The volume of a perfect gas increases 1/273 of its volume at 0 degrees Centigrade for every increase of 1 degree on the same scale. According to this, absolute zero corresponds to the temperature at which the same perfect gas would reduce to nothing.

WEIGHT PER HORSEPOWER

Editor THE AUTOMOBILE:

[1,980]—Will you advise me as to the standard set by automobile builders relative to the horsepower required to carry a certain weight of car. I had a car built using a 24-28-horsepower motor, the car complete weighing 3,200 pounds. The engine does not appear to work properly, don't seem to pull light and does not do the work as it ought. The wheels are 36 inches in diameter and the gear ratio on the high gear 3 1-2 to 1. I have no fault to find with the engine; it is simply a case of knowing if the car is built too heavy. F. G. W.
Pittsburg, Pa.

To arrive at any such figure as you desire, it will be necessary to assume a basis of figuring power, since different makers rate their engines differently. If, then, the A. L. A. M. rating formula is used as a basis, some figures may be given which allow of intelligent comparison. The matter of weights is not in the same category, however, since some unscrupulous manufacturers understate the car weight, others only approximate it, while a third class intending to give it correctly, do not state whether the given weight includes anything but the bare car or not. So, it is hard to obtain anything reliable in the weight line. The tables given in THE AUTOMOBILE at the time of the shows last winter were made up from information supplied by the car manufacturers, and as such, must be taken with a grain of salt.

Thus from the cars of the A. M. C. M. A., the figures for the class costing $1,000 or less, the average of sixteen different weights is 65.6 pounds per horsepower. The lowest figure was 45.8 pounds and the highest 141 lbs. The average horsepower in this class was 19.5 and the average weight 1,280.

In the class $1,000 to $2,000, there are 54 cars of different weight, of which the average is 1,985 pounds, the average power 29.2, and the average weight per horsepower 68.1, which is a slight increase over the cheaper cars. The lowest figure for this was but 44.4, and the highest 91 pounds, the range not being as great as before.

Class $2,000 to $3,000 includes but 28 cars of varying weight, of which the average is 2,510 pounds. The average power is 38.3, from which the average weight per horsepower is found to be 65.4, the lowest yet found. In this class, the lowest was 46.3 pounds, and the highest 167 pounds. The latter was a car having an unusually long stroke, 1.46 times the bore, and would not class with the others for this reason. Eliminating it, the highest weight is 86.0, so this class has also the lowest range of weight values.

Next in order comes the class $3,000 to $4,000, in which are found but 26 cars. These average in weight 2,980 pounds and 41.6 in horsepower. The average weight per horsepower is the highest yet at 71.8. The range of values is also large, 52.5 pounds for the lowest and 107.5 pounds highest. The greatest power was 54.1 and the lowest 25.6. The greatest weight was 3,500 pounds and the lowest 2,250 pounds.

Combining all other cars into one class above $4,000, only 21 are found. The power of these varies from 32.4 up to 72.6, while the weight may be anything between 3,100 pounds lowest and 4,400 pounds highest. The average horsepower is 49.7. The weight averages at 3,550 pounds. Dividing one by the other, the average weight per horsepower is 71.4, lower than the previous class. The range of weight values was from 48.2 lowest up to 111 highest, this being on a limousine.

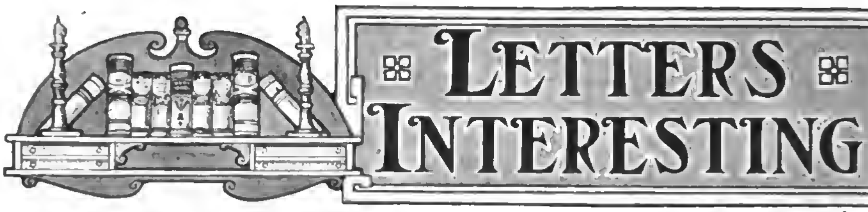
Summing up the whole five classses into a grand total, there are 145 cars, varying in weight from 900 up to 4,400 pounds and in power from 6.4 up to 72.6. The average weight was 2,418 pounds, the average power 35-horsepower, and the average weight per horsepower, the desired quantity, 69 pounds. Incidentally, the least weight per horsepower was 44.4 pounds in the second class, and the highest 167 pounds in the third class, next to which comes 141 pounds in the first class.

Viewed in the light of the above figures, your car is slightly underpowered for its weight, as you thought. The motor would be rated at 28-horsepower, which makes the weight per horsepower 114 pounds, as against the figure of 69 pounds above. Taking the latter into the weight of your car, and allowing 100 pounds more weight for the larger engine, your car should have a 48-horsepower engine. This will be obtained, according to the rating formula in a four-cylinder engine of 5 1-2 inch bore and in a six-cylinder motor of 4 1-2 inch bore.

MORE WHITE ENGINE

Editor THE AUTOMOBILE:

[1,981]—In reading over your valued publication of date, August 5, we notice the letter from B. F. Ulmer in regard to our rotary valve engine. Now, we are very sorry that this got into print, for we have been trying to keep it a secret until we had developed it to a state where we could place it on the market in competition with the poppet valve engine. Since something has been said about it, we will add that it was built solely for experimental purposes, to determine the relative efficiency of the rotary and poppet form of valve. The results obtained were very satisfactory, but as yet we are not ready to give out the details, other than the fact that the valve is placed directly in the head of the cylinder, which position permits of a spherical combustion chamber. In this way we are able to get a valve opening of 4 1-2 square inches on a 3 5-8 inch diameter of cylinder. We have in course of construction an engine which we hope to exhibit at the automobile show here next fall, which will dispense with all poppet valves, cams, springs, packing, water pumps, water connections, radiator, and many other parts. This engine is almost silent, or as near so as a dynamo. You will note from our description above that there is nothing to make noise. We developed the type of valve used by the Frenchman five years ago, but discarded it for the present one because we are able to get twice the valve opening with the same size. Despite faults, it is superior to poppet valves. Regretting the premature publication of this,
Atlanta, Ga. W. H. and E. F. WHITE.



CONTEST SUGGESTIONS

Editor THE AUTOMOBILE:

[1,982]—As it is proposed shortly to hold another 24-hour race at the Brighton Beach track it would seem as if a special opportunity is offered to those manufactures using air-cooled motors, two-cycle motors and slide valve motors to demonstrate in a convincing and readily understood way that these motors have the advantages claimed for them without the faults which they are commonly thought to possess.

It is true that the vehicles on which they are used have performed well in special tests and in endurance contests, but it is surprising how few users or intending users of motor vehicles know of these performances and many who have heard of them do not fully understand the methods of scoring and cannot appreciate the relative advantages shown by the different contestants.

Moreover, 24-hour contests, in addition to being readily understood by every one and consequently of more general interest, contain less of the element of luck (particularly after the first few hours) than most other contests and less opportunity for deception as the troubles of the contestants can be fairly well seen and any imperfections developed not attributable to mechanical inferiority can be allowed for.

Of course, some makers claim that they do not believe in such contests because of the danger (this has largely been eliminated by the removal of the fences and the provision of fairly level ground for the cars to run on if they leave the track at a turn), but in the opinion of many people this announced belief would possess little weight with these makers if they were more certain of making a good showing.

It would certainly seem as if even a creditable showing of a vehicle having one of the above mentioned motors would benefit its makers more than thousands of dollars spent in special tests, in contests of little general interest and in trying to convince the public by means of claims made in advertisements.

In closing, and in fairness to the most prominent makers of the slide-valve engine car, it might be well to point out that, in addition to its being an imported production, their abstaining from such contests may be due to the fact that it has only lately been marketed by them and they may not have had time to give such contests consideration, particularly as 24-hour races are as yet unknown in Europe. It would, however, be very interesting to have this type of car entered and even if it could only be arranged to enter one of the vehicles which have been imported for private parties it would seem as though the makers would benefit, as any handicap under which it might be operated would be, to a great extent, considered by the public. A. E. OSBORN.
New York City.

While suggestions of this sort are always welcome, it is rather difficult to see how a contest of the kind proposed above, namely, a 24-hour race between cars with air-cooled, two-cycle, and slide-valve engines, would serve any useful purpose. Unless we are very much mistaken, the races as planned are intended to bring out the merits of a number of competing cars, that is, cars which are natural competitors, aside from the matter of price. The cars mentioned do not compete with one another, but rather each stands in a class by itself. So, it would appear that such a contest would not fill in the simple matter of number of entries. Who could blame the makers of air-cooled engines for not caring to pit their product against two-cycle motors, or either one of them against the newest wonder, the slide valve engine?

ANSWERED AND DISCUSSED

CHAIN OR SHAFT?

Editor THE AUTOMOBILE:

[1,983]—Will you please advise me of the relative merits of the two following forms of construction: two-cylinder opposed engine set lengthwise of the car and driving by chain, and two-cylinder opposed engine set crosswise under the hood, driving the car by shaft.

Now that I have disposed of my single-cylinder car, it behooves me to advance one cylinder towards the four and my preference has been for the last mentioned car until recently, when a local automobile man undertook to convince me of the superiority of the former type of construction. He says that the last named method of placing the engine does not allow it enough room, and that, having a lack of room, it will also lack both speed and power, because it hasn't room enough. Similarly, the engine of the form first mentioned happens to have a slightly longer stroke, which he claims will give more power, therefore the car with that engine will travel farther in a day's run than a car equipped as in the second case.

In other words, I would appreciate your opinion of the relative merits of a two-cylinder engine placed in the two different positions. Also, what other considerations go with a two-cylinder engine that might make for or against speed and power? Why is a four-cylinder engine so far superior to a two? F. K. GREEN.

Louisville, Ky.

Your friend was wrong, radically wrong when he said that a lack of room for the engine would prevent it from developing either power or speed, for the engine could be hung on the roof, carried in your arms or put into any old position, whether there was room enough for it or not, and it would develop the same amount of power from a given quantity of fuel. So, if the fuel supply was all right, the position would not influence the power output in the least.

Your friend was also wrong when he stated that a longer stroke engine would carry a car a farther distance in a day than a short stroke. As a matter of fact, if the gear ratio was the same, the shorter stroke would carry your car farther, since to develop the same power necessary to propel the car the short stroke motor must turn over at a higher number of revolutions per minute. Consequently, this form of engine would carry the car farther in a given time. If the gear ratio of the car having the motor with the longer stroke were altered to compensate for the lower speed of rotation, the two cars would travel the same distance, always granting that the two engines were equally well made, so that the fuel economy would be the same.

Speaking of the stroke alone, without regard for the car or the gear ratio, the long stroke engine is supposed to give more power than the short stroke. That is regardless of speed, but seeking power and maximum power alone, a 4 by 6 engine will give more power than either a 4 by 5 or a 4 by 4 engine.

The real argument in the two cases you cite seems to be the relative merits of the chain and shaft for final drive, since the two engines were placed as you found them for the purpose of obtaining the different drives, across the car for shaft drive, and parallel to the axis of the car for chain drive. So, it is a question of chain or shaft, which? Chains are said to be more efficient than either spur or bevel gears, yet nearly 90 per cent. of the automobiles made to-day are shaft drive. This shows that other considerations enter into the matter than just the mechanical efficiency. Thus, chains are noisy, shaft is quiet; chains are very difficult to enclose satisfactorily, and when so enclosed are difficult to adjust and otherwise attend to; shafts are easy to enclose, in fact, all of them are found enclosed on the cars to-day. When not enclosed, chains gather dirt and thus wear rapidly; shaft being always enclosed does not gather dirt and dust, thus outwears chains. Less wear means less adjustment and less care. Chains are hard to lubricate; most shafts are packed in grease or oil, and are self-lubricating. If one of the chains break, on a double chain driven car, it is helpless, and must be towed home. So, too, with a single chain drive, but with a shaft drive, this seldom if ever happens. That is, it very seldom happens that a derangement of the propeller shaft puts the car out of commission.

To go back to the two different engine locations, the fore and aft one would seem to have some disadvantages not previously mentioned. Thus on climbing a steep hill, the front cylinder rises and the rear one falls relative to the crankshaft center line. This would conduce to poor lubrication within the cylinders, as the oil in the rear cylinder would all flow into the cylinder head, the lowest point, where it would mix with and dilute the incoming mixture, while the lubricant in the front cylinder would run to the low point, which is the crankcase, resultiing in both cylinder bores being without oil, or one without any and the other flooded. The engine placed across the frame would not be subject to this annoying trouble.

A four cylinder engine is superior to a two, just as a two has the advantage over a single cylinder, and as a six has "it on" a four, in the frequency and regularity of firing. That is, considering any two revolutions of the crankshaft, the single cylinder has one power impulse; that is, fires once. The two cylinder engine gives two impulses; the four produces four power strokes, and the six, six. As each revolution means two strokes, two turns will be four strokes. The four engines compared, then (if of equal power), will give: one tremendous power stroke in every four; the two cylinder produces two power strokes in four, each therefore being of lesser magnitude; the four cylinders turn out four still smaller impulses in four strokes, one per stroke; while, lastly, the six is so constituted as to produce six power strokes, an average of one every two-thirds of a stroke, and all of still smaller size than those of the four. You can readily see that the smaller the impulses and the more frequently they occur, the more quietly will the engine run, and the smaller will be the wear and tear on the whole of the mechanism.

CEMENT FOR RUBBER

Editor THE AUTOMOBILE:

[1,984]—Will you please let me have several formulas for cement to be used in patching inner tubes. M. H. P.

Newark, N. J.

In any cement for rubber, the cement must come in contact with the rubber, which result is obtained by brushing the surface with naphtha. This softens the rubber, and when partially evaporated leaves it in as nearly favorable condition for adhesion as it is possible to get.

Among the many cements used in rubber manufacture is marine glue. This consists of a pound of the crude rubber (caoutchouc) to one gallon of coal-tar naphtha and twenty pounds shellac, heated gently and poured upon metal plates to solidify. In using, small pieces are melted at 250° Fahrenheit. If required in a liquid form use more naphtha.

A good gutta percha cement is made of two parts of common pitch and one part of gutta percha, melted together and well stirred. When ready this is poured into cold water, which transforms the cement into a hard, brittle substance. To use, this is softened by heating, and at 100° Fahrenheit is a thin fluid.

The basis of nearly all good cements used in tire repairs is either india rubber or gutta percha dissolved in any one of the common solvents, which include benzine, carbon-bisulphide, chloroform and ether. Various other ingredients are necessary for a good cement, as, for instance, if quick drying is desired, some form of dryer is added, and to attain tenacity still other gums, such as rosin, mastic, gumlac, are used.

PLANS FOR A GARAGE

Editor THE AUTOMOBILE:

[1,985]—I want to get plans and suggestions for a small garage which I am about to build. Have you published anything of this kind? If so, kindly send it along. H. M. W.

Dayton, O.

No, we have not published anything that will help you in this matter, but a garage article now in preparation will cover all of the present tendencies in garage construction, and will doubtless furnish you the information you wish. All materials will be dealt with, for the man who wants to build. It will be complete in several numbers, beginning in an early issue.

TWO AND FOUR CYCLES

Editor THE AUTOMOBILE:

[1,986]—Will you kindly inform me through "Letters Interesting and Instructive" just what is meant by two-cycle and four-cycle engines. There are so many different opinions about this that I am very much puzzled to know which is which, and would be glad to have you give me something definite and something upon which I can depend.

Plattsburgh, N. Y. H. J. LANGLOIS.

The difficult thing in this explanation is to make it so simple that anyone, whether versed in mechanics or not, can readily grasp the idea. You doubtless know that in the operation of a gasoline engine there is a regular succession of events, which must occur in the same regular, unvarying order every time. This is called a cycle of events, or, for short, a cycle.

Now automobile engines may be so constructed as to have this cycle take place in varying lengths of time as determined by the number of strokes made by the piston. That is, the cycle may be completed in two strokes, or in four strokes. In the former case the engine is said to work upon a two-stroke cycle and is called a two-stroke cycle engine, the word stroke usually being omitted. In the latter case when the cycle of events is completed in four strokes, the engine is called a four (stroke) cycle engine. There is also an engine built which operates upon a six-stroke cycle, but not being in common use this is not worthy of further attention.

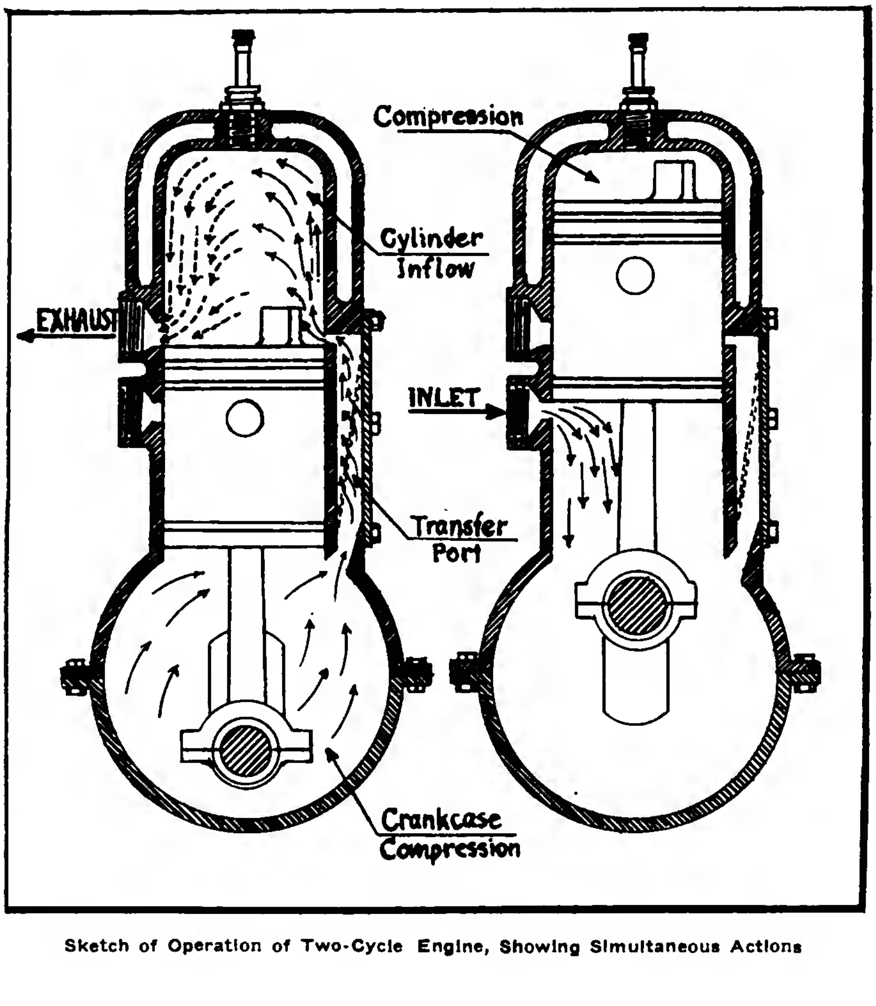
The cycle of events and the order in which they happen is as follows:

1. Suction, or drawing of the fuel.
2. Compression, or increase in the pressure of the fuel mixture.
3. Expansion, following the firing of the compressed charge.
4. Exhaust, or cleaning out the cylinder, so as to resume the first operation, or to allow of repeating the cycle of events.

In the four-cycle engine the first down stroke completes the first action (1), that is, the downward motion of the piston causes a partial vacuum into which the fuel rushes. The stroke being completed and the cylinder filled with gas, the return stroke compresses the charge, action number (2). A spark is then made in the cylinder containing the compressed charge, which burns or explodes more rapidly for having been compressed. In burning or exploding, the gases expand and drive the piston down the second time, this being action (3), and the only useful part of the whole cycle, in so far as producing power is concerned. At the close of this stroke, the cylinder is filled with burned and consequently useless gases, which the ensuing upstroke pushes out into the air or at least out of the cylinder, so as to make place for the next charge of unburned gas. This is action number (4), and concludes the cycle.

In the two-cycle engine, all this takes place in two strokes of the piston, one up and one down, just half the number necessary in the four-cycle. As the cut shows, the left-hand view is that at the close of the expansion the burned gases are exhausting through the exhaust pipe, while *at the same time* the fuel is entering the cylinder from the crankcase, where it has previously been partly compressed. The other view shows the condition just previous to expansion, and at the time when the spark is made to ignite the charge. The fuel in the cylinder has just been compressed, while *at the same time* the fresh charge of fuel was drawn into the crankcase base. The *italics* indicate that to perform the needful actions it is necessary to double up, and it is this doubling up which has held the two-cycle engine back, for with two things taking place in the cylinder at the same time it is hard to say when the one stops and the other commences. This is highly important, as may be seen from a single instance. Thus, how is it possible to stop the fuel from following the exhaust out of the cylinder and in this way waste some of the fuel? Or, on the other hand, how is it possible to have all of the burned gases expelled from the cylinder, so that none of them remain to dilute and render useless part of the simultaneously incoming fresh fuel?

Be that as it may, there is a power impulse on every down stroke, while in the four-cycle engine there is a power impulse on every other down stroke. This statement would lead a person to think that a two-cycle engine would develop twice as much power as a four-cycle of the same dimensions, but such is not the case. Far from it. The very best of two-cycle engines will not develop much over one-fifth more power than the same sized four-cycle.



Sketch of Operation of Two-Cycle Engine, Showing Simultaneous Actions

FIRST BLOCK MOTORS

Editor THE AUTOMOBILE:

[1,987]—I am an American and proud of it. My grandparents on both sides were ditto, and my sense of justice is well developed, I trust. So it grates when I see an able editor giving credit to a foreign country that belongs to America.

On page 70 of your issue of July 8 you give the French credit for originating the block system of casting auto motors. Now I would not take a single bit of credit from them that they actually deserve. They and their good roads have done much for the auto; but bless you, the block method of casting auto cylinders was used on Duryea double cylinders as far back as 1894. It was continued in '95 and '96, and in '97 the triple cylinder was designed, built and sold for the next ten years. In 1897 a four-cylinder Duryea engine was built having the heads, water jackets, valve pockets, and in fact everything but the cylinder shells, in one piece. This is close enough to the present block method to be called a starter even if the others had never been built.

These various motors were mostly of 4 1-2 bore and stroke, but other bores from 4 to 6 inches were tried. They were shown at cycle shows as far back as 1897 and at every New York auto show from the first up to quite recent years. There is no chance to say that they were hidden and not known by the public. It was a two-cylinder block engine which drove the winning Duryea in the first British event in '96 when it defeated the best three rigs of the French race of that year. CHARLES E. DURYEA.

Reading, Pa.

It was not the intention to deprive Mr. Duryea of any credit naturally due him. So, perhaps it should have been said that the French were the first to push the *en bloc* construction, adopting it widely.

IN in the development of models for 1910, the E. R. Thomas Motor Company, Buffalo, N. Y., took into account the lessons taught by the British "Four Inch" race and incorporated the results thereof in the latest production of the big factory on Lake Erie. Prime among the benefits accruing from that particular race was one that the whole automobile world has now learned, the very marked advantage of the long-stroke motor, both in power and in speed, wear being reduced incidentally.

E. R. Thomas has just returned from a five months' tour of the automobile factories of Europe firmly convinced that the most important new feature for 1910 on the other side will be the long-stroke motor. In explaining his company's departure from past practice as exemplified by the relative bore and stroke of the new model, Mr. Thomas had this to say: "By the long-stroke motor is meant one in which the travel of the piston is greater than the diameter of the cylinder bore. Heretofore, most motors have been what is termed short or square; that is, the stroke was either less than or equal to the bore. The long stroke has the advantage that the engine does not have to revolve so fast to deliver its power. Thus, a 4 by 4 engine must run at 1,500 revolutions to develop its A. L. A. M. rating, while a 4 by 5 motor, which is rated the same, would only have to run 1,200 revolutions, and a 4 by 6 would have to make but 1,000 turns."

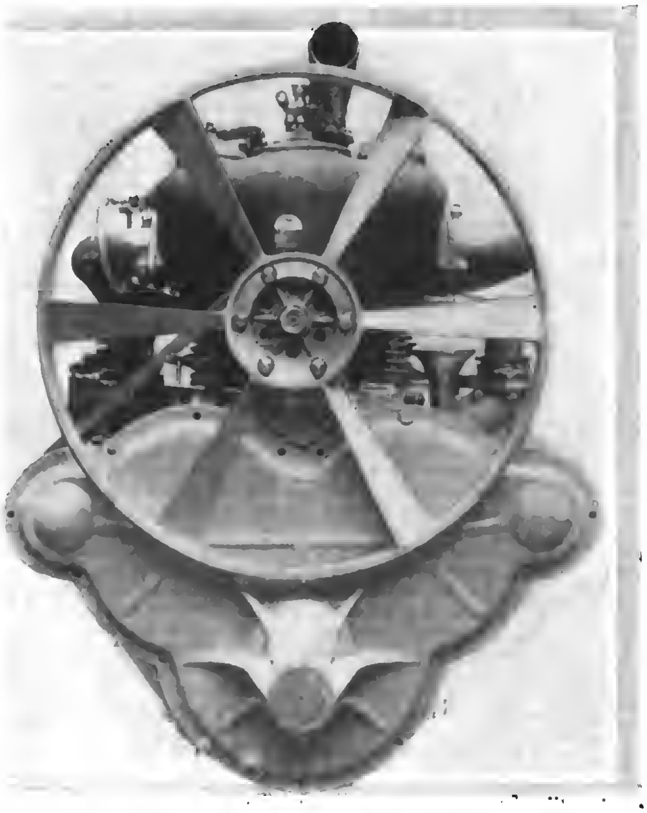
Newest Addition to Thomas Family Will Have Long Stroke—So it is that a new car has been added to the list of Thomases, a little "six," and this will be equipped with a long-stroke motor. The motor in detail is four-cycle, water-cooled, six cylinders, of 4 1-2-inch bore and 5 1-2-inch length of stroke. This gives a ratio of bore to stroke of 1 to 1.22, as compared with the 78 engines shown at the A. L. A. M. and A. M. C. M. A. shows in New York City last winter, which averaged but 1.14 for the value of this ratio.

The cylinders are cast in pairs, another departure from Thomas practice, and are exceedingly well water-jacketed. At the lower part of the cylinder the water-jacket is tapered to force more water to the top and hotter parts and less at the lower cooler portion. Moreover, the valves have been completely water-jacketed, and the stems of the valves are taken care of in the same thorough way. This prevents deformation of either valve seat or cylinder head.

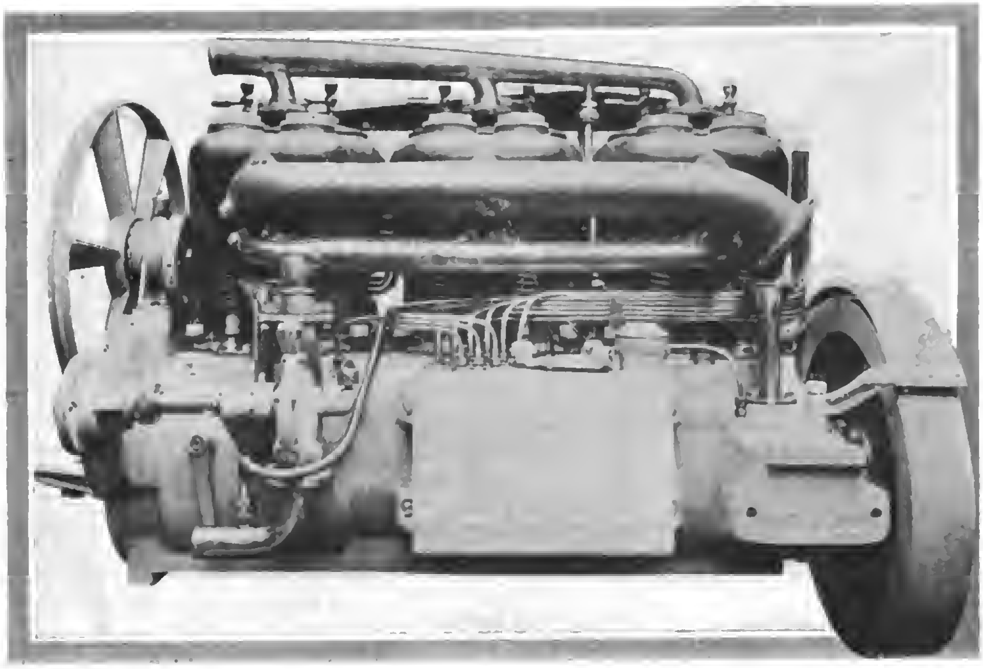
The cylinders are of what is known as the "Tee" head type; that is, they are symmetrical about the center line, the valves being located on opposite sides, inlet on the right and exhaust on the left. This form of construction lends itself well to the use of four bearings on the crankshaft, one at each end and one between each pair of cylinders.

Within the cylinders are placed the long pistons, with many rings. The length of the pistons is actually equal to the stroke, namely 5½ inches, and four narrow piston rings keep the cylinder heads gas tight. The connecting rod is also long, being more than twice the stroke length, that is, 11¾ inches.

Model M, as the newcomer is to be called, has been designed with a full knowledge of the latest foreign practice in large valves, big ports, and easy, smooth gas passages. The clear valve opening is 2¼ inches, or just half the diameter of the piston. The exhaust pipe is a casting of large internal diameter and easy bends; this, in combination with the large valves, serving to clear away the burned gases very quickly. The inlet manifold, on the other hand, is of drawn copper tubing, carefully built up to the required shape by brazing. This makes not only a serviceable job, but a fine appearance as well. When the speed at which



Motor as Seen from the Front Shows Symmetry



Exhaust Side of Model M Long-Stroke Motor, Showing Pump and Oiler

The bolts are of nickel steel. Camshafts are of the same material, while all gears are either steel and hardened or of bronze. Flywheels are usually of cast iron, because it costs little, but the Model M flywheel is of cast steel, which is better adapted to withstand bursting strains. This makes it possible to use a larger diameter also, which is advantageous in the weight; the same weight placed farther from the center of rotation being much more effective, or, inversely, with the same effectiveness less weight may be used if it is located farther from the center.

The crankshaft, being the most important part of the engine, should be given the most care, and, in this case, it is. The material is a high grade of carbon steel, drop-forged and specially heat-treated by crankshaft specialists to bring out the best qualities.

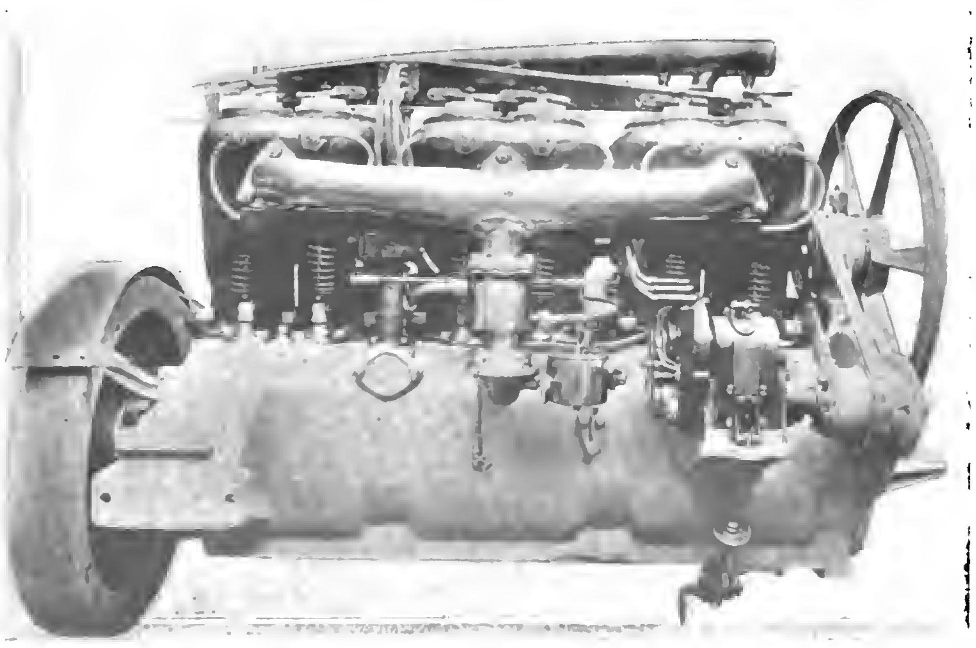
Three-Point Suspension for Crankcase—One of the newest ideas as expressed in this engine is the three-point suspension incorporated in the crankcase. This case is a one-piece casting of aluminum, with two very wide strong feet at the rear and close to the flywheel. At the front the extended crankshaft bearing of the gear-case cover is machined to a circular form and is used for the forward point of support. The front gear cover, as is to be seen in the front view of the engine, is symmetrical about the center, the cam and auxiliary gears being located so as to balance. These shafts also locate the accessories, the shaft on the right side driving the magneto and the fan, while that on the left drives the centrifugal pump. Forward of the magneto, which is strapheld in place, is the pulley which drives the fan, this being of the six-bladed type with a rim, driven by a trapezoidal leather belt. Back of the magneto on the right side is placed the carbureter, and back of that, in turn, but closer to the cylinders, is the Unisparker. This is driven by bevel gears from the camshaft, and is located high up and midway between cylinders four and five.

the gases travel in and out is mentioned—upward of three-quarters of a mile per minute—the importance of the size and proportions of the pipes will be appreciated.

Quietness Obtained in Many Places by Many Devices—One of the places where the noise has been reduced—and they are many—the valve plungers have been provided with fiber inserts, and the clearance reduced one-half of that ordinarily used. This combination makes an absolutely noiseless valve action. Another instance of this is in the gears for the camshaft. These are of steel and bronze, the camshaft gear being a pair of bronze helical gears, riveted together to form a single gear of herringbone tooth outline. This is well known for its quiet running qualities; so much so that the expense of cutting the double gears was not considered. Throughout the motor the materials have been selected with care, as will be seen in a mention of some of them. Thus the piston rings are of special iron developed from an exact cupola formula for this purpose. The connecting rods are of government specification nickel steel, with sulphur and phosphorus together limited to .04 of 1 per cent.

Nothing but the pump is placed on the left, the water entering from below, passing through the pump directly upward into the tapered section copper pipe, which divides, one branch to the rear for cylinders five and six, and one forward for the other two cylinder blocks. The water outlet is on top of the cylinders, just off of center to the left, the compression relief cocks being located on the center. This pipe rises gradually to its greatest height just at the radiator connection, the section increasing at the same time, and in the same way.

The bottom of the crankcase is closed by three handhole plates, these being ribbed to make them stiff, while being of very thin section and light metal, aluminum. The front one has a cored passage across the bottom, to the outer end of which is attached a cock and gauge glass. By reaching down and opening the cock, the oil rises in the glass to the same height as that within the case. If too low, more oil may be added through the vent pipes, of which there are two on the left side, the



Inlet and Ignition Side of the New Engine, Showing Cooling Fan and Belt rear one communicating with the interior through the hollow crankcase foot.

The oiler is fastened to the left side of the case, back of the pump, four bolts serving to make it practically an integral part of the case. From it about a dozen leads conduct the lubricant to the various parts which have forced lubrication.

Very Large, Liberal Bearings—Bearings interest everyone, for, no matter what else is right, if the bearings are not, it is dangerous to run the engine. On Model M the crankshaft is 1⅞ inch in diameter and provided with four bearings of a high grade of babbitt, die cast to insure absolute interchangeability. The total projected area of the four is 52.6 square inches. The same material is used for the big ends of the connecting rods, while on the camshafts bearing bronze is used. Each camshaft is provided with bearings which total 11.3 square inches projected area. This gives 22.6 square inches total for both shafts.

Perfect balance is obtained in two ways—every part is balanced on the ways for static balance; then, when completed and assembled, the units are tested for correct running balance. This constitutes the first part, while the second consists of machining the combustion chambers of the cylinder castings. Furthermore, these are measured and selected so as to match up, a set of six which exactly agree being selected for each engine. This care in balancing insures equal charges, equal explosions and equal expansions, all of which result in a quiet-running engine.

Double Ignition Features Show a Difference—It has come to be a trite saying that the motor is fitted with double ignition, two separate and distinct systems, so only the details of this one will be given. The two sources of current are a high tension magneto, Bosch, and the Atwater-Kent Unisparker for the second. The spark plugs for the latter are placed on the top of the cylinders, the wires being carried across the cylinder heads in an enclosed bus bar. The same method of procedure is carried out for the magneto, the plugs for which system are screwed into the side of the cylinders, projecting into the inlet valve pockets, as do also the other set. Among the little things worthy of mention is the ball and socket joint for operating the magneto, this being adjustable to very close limits.

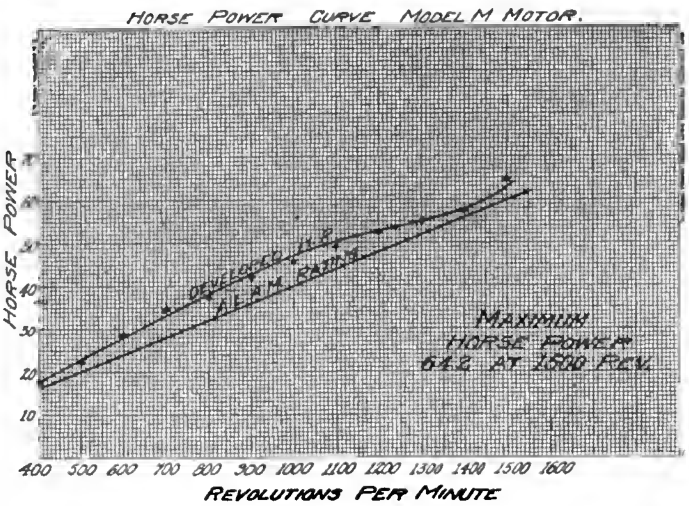
With this engine is used the three-disk clutch of which Thomas is the most consistent advocate. This is carried on two imported annular bearings, is provided with double adjustment, and is fitted with cork inserts. Back of the clutch and ahead of the transmission are placed two universal joints, of the internal gear type, which have stood up so well in motor truck service.

Transmission Shows Very Careful Designing—The gearbox is a very small, compact piece of mechanism. Some idea of the compactness may be obtained from the bare statement that the distance from center to center of the annular ball bearings, upon which the countershaft is mounted, is but 8 7-16 inches. Six of these bearings are used in all. The gears are of nickel steel, heat treated, hardened and quenched in oil. The net result of all this care in design and selection of material is that the complete gearbox weighs but 82 pounds.

In the rear axle Timken roller bearings are used throughout, the rear axle itself being a piece of Timken work. The axle casing is of pressed steel. Gears are of four pitch, and the gear ratio is three to one. In this axle the wheels are driven by jaw clutches at the outer extremities, the axle being known as of the full floating type.

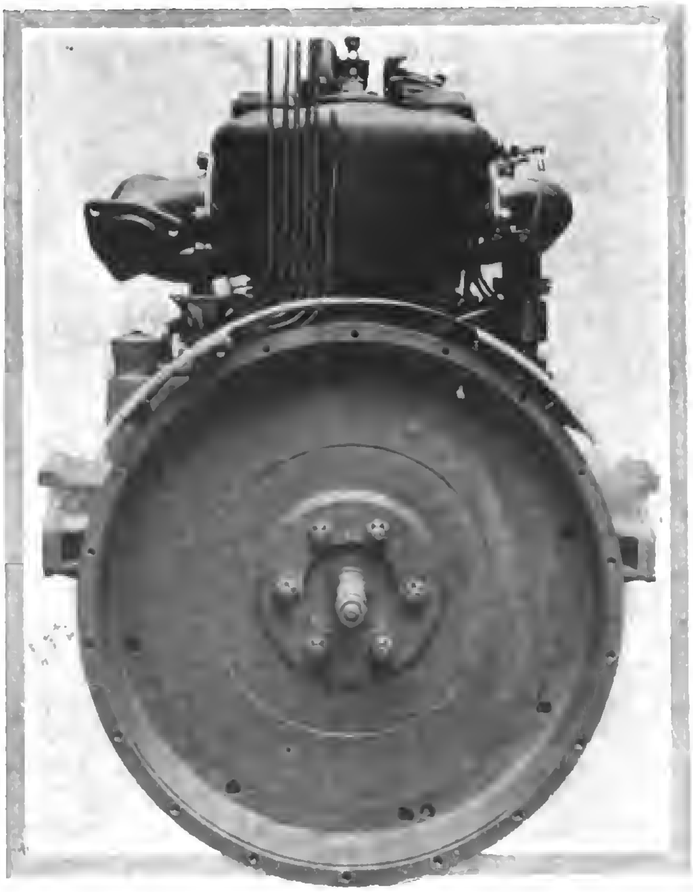
The front axle is a nickel steel I-section forging of large sectional area, as are also the knuckles and steering arms. The springs are of alloy steel, semi-elliptic being used in front, and three-quarter scroll elliptic in the rear.

Fenders and running boards, as well as the sheet-metal aprons, were the source of much attention to make the protection to the passenger perfect. The front fenders have a droop at the forward end which, together with the metal lip there fitted, prevent forward splashing, while a connection between fender and frame prevents side splash. The running board and the rearward extension of this connection eliminate danger from this source to the driver. At the rear, the same idea is well carried out by connecting the fender to the body or running board around its entire length.



Curve of Horsepower Obtained by Test

This Model M is made in six styles of body: touring car, runabout, tourabout, flyabout, limousine and landaulet. The open bodies are finished in royal blue with straw running gear, while the closed bodies are done in maroon with French gray, all being of hand-hammered aluminum construction. The touring car seats five and lists at $3,500, at which numerous extras are included. A few of these are: Speedometer, top, Prest-o-Lite tank, glass front, two oil side lights and tail light, robe rail, etc. The wheel base of the chassis is 125 inches and the tread standard. With full load of five passengers, all gasoline, oil and water tanks full, Model M has one horsepower A. L. A. M. rating for every 94 pounds weight. On the basis of the power the engine can develop, this is reduced to 50 pounds.



Rear View Displays to Advantage Flywheel Size

Chalmers-Detroit 1910 Presentation

"Forty" Touring Car — "Forty" Roadster

CONTINUED with slight and minor modifications, aptly describes the two models which the Chalmers-Detroit Motor Company, Detroit, will present for the season of 1910. These two cars will be the two made for 1909, with such alterations as a year's service has shown to be advisable. Naturally enough, these are few in number and small in their influence on the appearance and construction of both models. Being so little changed, both of them will be continued under the same name, that is, the small car will still be called the "30" and the larger, more commodious, more pretentious outfit will be continued as the "Forty." The former will be fitted with various bodies to suit every taste, from a three-passenger runabout to a five-passenger touring, several special productions being featured, such as the inside driven coupé, which can be instantly altered to a three-passenger runabout. The more powerful chassis will be made with bodies of three types, seven-passenger touring, pony tonneau and roadster. All of the bodies will be built of the same materials, which have proven so satisfactory in the past, namely, aluminized sheet steel and wood.

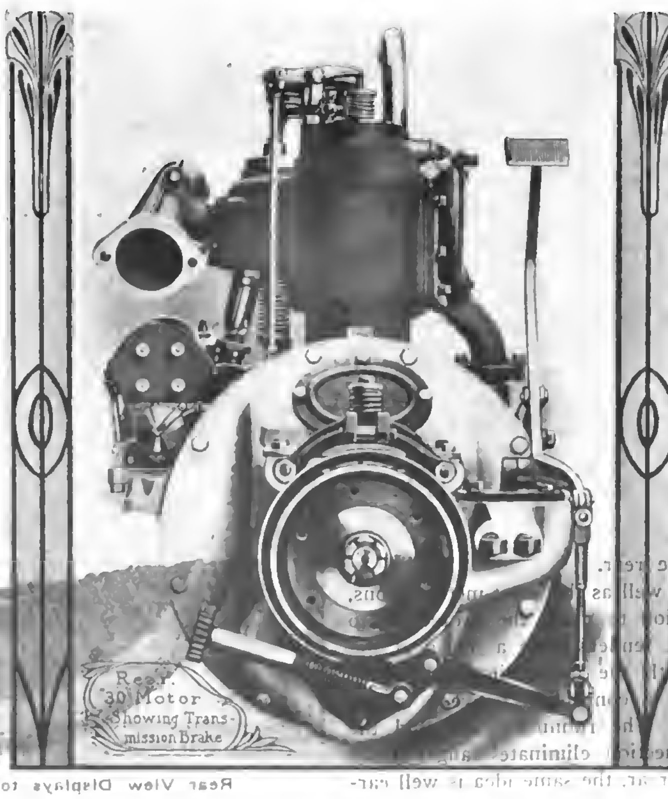
Larger Bore Means More Power—On the "30" chassis an engine will be used which is almost an exact replica of the 1909 engine, except that it has been made more powerful by an increase of 1-8 inch in the diameter of the cylinder bore. This makes the motor dimensions 4 by 4 1-2, which, according to the rating formula, would increase the power from 24 to 25.6 horsepower. The oil pump has been placed in a more accessible position. Whereas this was formerly placed in the bottom of the crankcase, in the oil well, it is now located on the exterior of the upper part of the case, opposite cylinder number four. A small plunger pump is driven from the camshaft of this cylinder, the inlet cam doing the work of operating the plunger. This is the prime mover in the circulating positive feed oiling system, which is otherwise retained complete. In this system the oil is pumped through a sight feed on the dash to the main bearings, whence it drips to the bottom of the case. There the collected pool of lubricant forms a splash system to cover the whole interior of the cylinders with a mist of oil.

The new exhaust pipe retains the admirable features of the old, including the very large diameters, easy bends, and other ideas which, combined with the big diameter exhaust valves, serve to clear the cylinders both quickly and effectively of the burned gases. The exhaust pipe itself, is, however, changed and now has individual leads from each cylinder. Whereas, the cylinder leads formerly started right downward, the newer pipe begins at number one cylinder and rises. So, too, does the pipe from number two, but between the middle pair the downward slope is commenced which continues unchanged right to the muffler, placed near the rear of the chassis. This makes the gases turn but one abrupt curve, that from the valve pocket to the pipe, and one easy one, in the middle of the exhaust manifold. The gases from the two rear cylinders turn but the once.

Aside from these changes, the motor is identical with that of 1909. The crankshaft is still mounted upon two large diameter ball bearings. The crank pins are 2 1-4 inches in diameter, hardened and ground. At the front, the camshaft and auxiliary shaft are driven by spiral gears from the crankshaft, this form of gear being utilized to lessen the noise. The cylinders are still cast in a block, with large inlet valves located in the top of the cylinder heads. This has been a feature of the Chalmers motors since their inception, and has been one of the features which enable the engines to develop so much power compared with the small piston displacement.

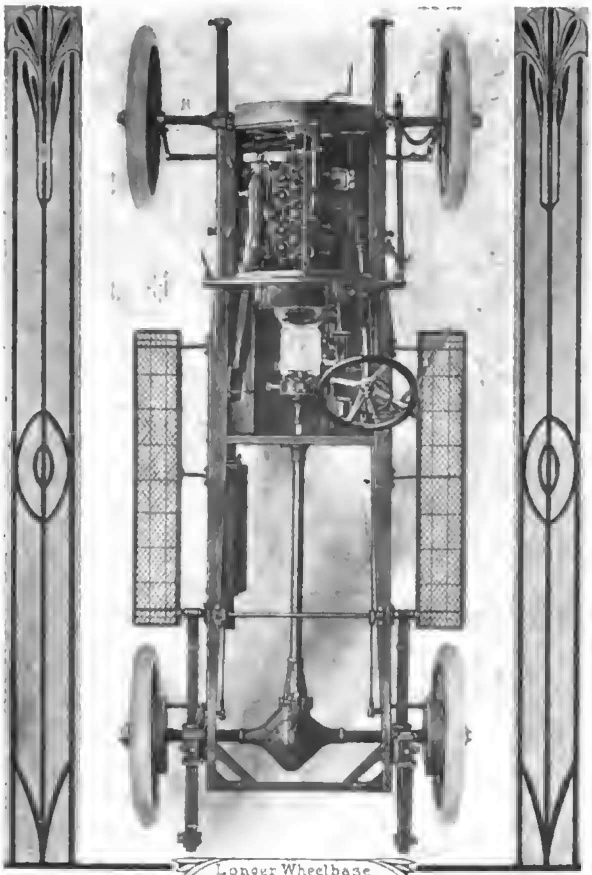
Multiple Disc Clutch Consists of Steel and Bronze Plates—The clutch is another part which is retained without change. This, it will be remembered, consists of alternate steel and bronze plates, the latter being connected to the flywheel and the former to the main driving shaft through the medium of keys. Three sets of spiral springs are used equally spaced around the periphery. These are of small diameter and medium size wire so that the pressure necessary to declutch is very small. Like all disc clutches, this one runs in a bath of oil, resulting in the gradual engagement of the clutch when the pedal is freed and the springs allowed to press the plates together.

Unit power plant construction is another Chalmers identification which needs little explanation or description. The transmission is a unit bolted up to the rear of the engine base and carries the clutch within. The three speeds and reverse operate selectively. Trans-



Rear "30" Motor Showing Transmission Brake sion bearings are all of the annular ball type, while the gears are of chrome nickel steel, carefully heat treated. The teeth are of large pitch and mechanically chamfered to render gear shifting easy. The shafts are of alloy steel and the gears are arranged upon them in as compact a manner as possible. This makes a small but very strong and stiff transmission case.

Brake Arrangement—Following the usual Chalmers practice, one transmission brake is provided immediately behind the gear case actuated by a foot pedal. A pair of internal expanding brakes operated from a side lever are placed directly on the rear wheels. The placing of the foot brake on the transmission has a number of advantages, among which may be mentioned: The increased braking power owing to the drum being geared up from the wheels; simplicity; cleanliness; obviation of clogging of braking toggles which occurs in the inside brakes mounted on the wheels; the removal of all superfluous weight from the axle, this being distributed over four wheels, and the consequent saving in tire wear; complete equalization of braking effort between the two wheels independent of the condition of the braking or road surfaces. As against these advantages, only one imaginary disadvantage can be cited, and that is the transmission of the braking effort through the rear axle driving mechanism. However, this mechanism must be amply strong to allow the motor slipping the rear wheels under all condition of load and road surfaces. The braking effort can't possibly exceed this. In fact it must always remain somewhat less. A brake placed on the transmission can therefore never strain the driving mechanism quite as much as the motor itself is capable of doing.



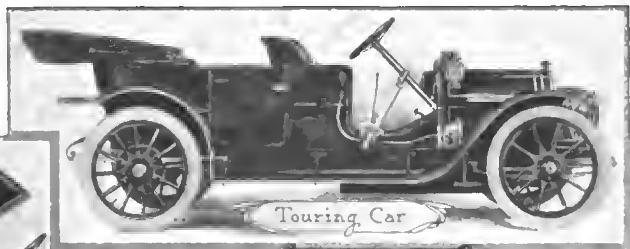
Longer Wheelbase Makes "30" Chassis Look More Simple

Details of the Final Drive—Directly back of the transmission and brake drum is placed the first and only universal joint. This is bushed with removable steel bushings and is enclosed in a metal case to keep lubricant in and dirt out. At this point is attached the forward end of the torsion sleeve, which surrounds the nickel steel driving shaft, and is bolted at the rear end to the axle casing. This sleeve renders unnecessary the usual torque rod and radius rods as well. It takes both driving and braking strains, while insuring rear axle alignment at the same time. Needless to say that it is of a very superior material, selected for its ability to withstand just such complicated strains.

From the propeller shaft the power is transmitted to the rear axle through bevel gears and the usual differential. The balance gear is of the bevel type, four pinions being used. This is very compact and the construction of the housing or case for it is such as to permit of its ready removal by simply taking off the cover and withdrawing the axles far enough to free it. The axle is of the full floating construction, which means that the weight of the car is carried on the sleeves surrounding the axles proper. The latter, then, simply transmit the power. Since they do not carry any weight, they may be withdrawn at will and while the car is standing on the wheels. This is effected by making the axles with six jaw clutches at the ends, which clutches do the driving. By taking off the hub caps, these are exposed to view and may be drawn out without the necessity for any tools. The construction of the axle tubing and differential housing has been improved by making the housing and tubes in one piece instead of the former method of using three pieces, riveted together. The new case tapers from the largest part of the balance gear out to the ends, which results in a very pleasing outline and strengthens the whole at the same time. Annular ball bearings are used on the axles, while the axle itself is of 3 1-2 per cent nickel steel, heat treated. The spring seats swivel upon the axle tube, which avoids twisting the springs, when obstructions are met that strain the two sides of the frame differently.

Steering and Larger Tires Conclude the Alterations—While the steering gear remains as before, the shifting or operating mechanism has been improved by enclosing it in separate casings. All steering parts are stout forgings, no castings being used on these important parts. The cross rod is behind the front axle and the reach rod above it, both being so placed for protection of these vital details. Steering arms are provided with bosses for the ready attachment of speedometers. Front wheels run on ball bearings and are fitted with larger wheels and tires. The wheels have been increased to 34-inch to improve the riding qualities, while 3 1-2-inch tires are fitted on four wheels.

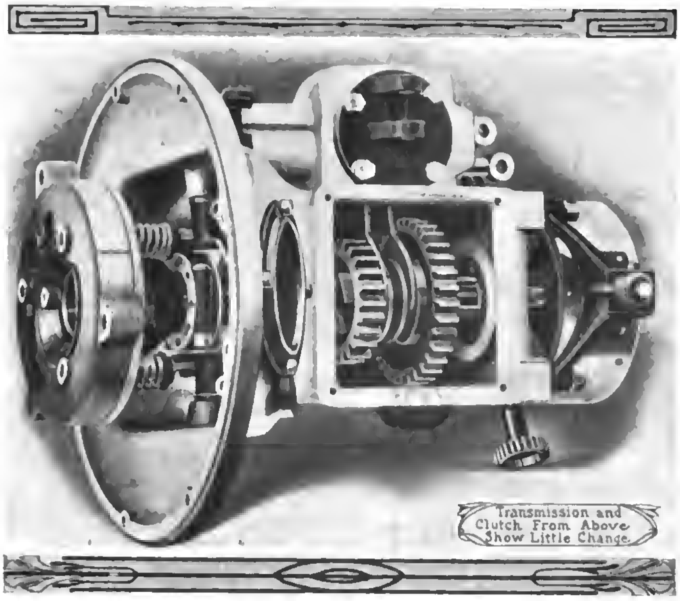
The frame, which is of pressed steel, shows one or two minor changes, as back of the front seat



Touring Car

Landaulet

Coupe



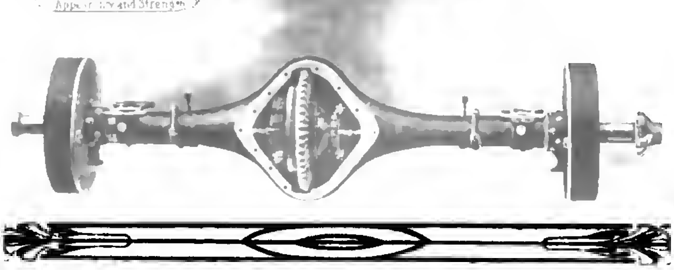
Transmission and Clutch From Above Show Little Change.

location it has been dropped in order to lower the rear floor boards, while a lower center of gravity is obtained incidentally. This section has been increased at the bend, the extra metal tapering gradually back to the very end of the frame. This extra metal is provided in both the upper and lower flanges, materially stiffening the frame. The section is a channel with the open side turned in toward the mechanism. The upsweep at the rear end is retained unchanged despite the additional forward drop just at the point where the tonneau entrance comes.

What the "Forty" Reveals That Is New—Generally speaking, the "Forty" shows a lesser number of changes than does the smaller car. These include a longer wheelbase, which results in a more commodious body; a change of position of the lay shaft in the transmission; ball bearings for the latter instead of the taper rollers of last season, heavier and stiffer frame; honeycomb radiator in place of vertical tube; and triangular torque rod consisting of two tubes, radiating from the front point of attachment to the axle casing. This last takes the place of the single tube formerly used, and gives increased stiffness and strength. The wheelbase shows a real change, the new figures being 122 inches as compared with the former figure of 112, an increase of ten inches, all of which is put into the tonneau or rear part of the body. This permits of making the capacity of the car seven passengers instead of five.

The same engine is used, 5-inch bore by 4 3-4-inch stroke, rated at 40 horsepower, according to formula. The valve sizes and location are unchanged, all being on the right side, in pockets. The crankshaft still has three bearings of good length and the material, die cast tin-babbitt. Oiling is the same. Like the motor, the clutch is unchanged, although the operating means is. This latter has been so changed as to permit of clutch operation with about one-third of the former spring pressure. In the transmission, the lay shaft has been moved from above the main shaft to a position below it. This works out to a reduction of the angle of the driving shaft, even with the larger wheels. The latter are now 36-inch in diameter, equipped with 4-inch tires all around. The rear axle will be of pressed steel, autogenously welded along the neutral axis, giving the greatest possible amount of strength for its weight.

[illegible] Axle Casing Tapered For [illegible] and Strength



The changed torque rod is worthy of more than passing mention. A triangular shape set on one flat side and presenting the point to the deforming force is the strongest shape known. The Chalmers engineers have taken advantage of this fact and have so shaped and set the torque rod that it has a triangular shape resting on a flat base at the rear end and presents a point, the forward end, to the deforming stresses, which tend to rotate the rear axle as the rotation of the engine shaft.

IMPROVED 1910 KISSELKARS ANNOUNCED

HARTFORD, WIS., Aug. 16—The factory of the Kissel Motor Car Company of this city has begun preparations for turning out the new series of Kisselkars, which, it is announced, will show many interesting changes. The publication of the 1910 specifications among the dealers has met a warm response and in consequence the factory expects a big demand.

This year's Model D-9 will be continued with slight changes as next year's Model D-10. It will, however, be rated at 50 horsepower instead of 40, though the refinements or increased dimensions which give this greater power have not been published. The wheelbase will be lengthened to 120 inches and the seating accommodations of the car will be made roomier. The change-gear will give four speeds instead of three. A great improvement in the appearance of the car has been effected by hanging the frame two inches lower. The price will be $2,000.

The smaller car, to be known as Model LD-10, will be built along the same lines as this year's 30-horsepower car, and will sell for $1,500. The wheelbase will be lengthened to 112 inches and the body will be altered to provide wider rear seats and more room forward of the front seats and in the tonneau. The general appearance of the car will be much the same as Model D-10. The body has been hung about three inches lower than formerly. This model will have double internal brakes, 34-inch wheels, and will be made both as a touring car and as a baby tonneau.

For those who wish a car of medium power but of ample capacity the new Model F-10 has been provided. This will be of 50 horsepower, seven-passenger, 124-inch wheelbase, and will sell for $2,500. It will also be built as a baby tonneau with 40-inch wheels. The adoption of this large size is another sign of the times, and doubtless before another year all makers of large cars will follow suit. There can be no doubt of the superiority of these large wheels over the old sizes from the users' point of view, as the cars equipped with them are much easier riding and also a shade faster. Last and largest of the Kissel line is Model G-10, the six-cylinder, 60-horsepower car, with practically the same features as the smaller models.

ADVANCE NOTES OF THE 1910 PULLMAN

YORK, PA., Aug. 16—The York Motor Car Company reports that it is turning out large quantities of Pullman cars and that it is making contracts so rapidly that its contemplated 1910 output of 2,000 cars will probably be completely allotted by the middle of September. The new model shows many improvements on previous ones. The power has been increased from 30 to 35 horsepower by lengthening the stroke from 4 1-2 to 4 3-4 inches. The radiator has been made correspondingly larger. A full floating type of rear axle is now used, with a double set of equalized brakes. The wheelbase has been increased by five inches, being now 112 inches, and the car as a whole is more richly finished than formerly.

Two Pullmans have been entered in the Munsey reliability contest to be run next month. The route lies through York, and the York Company has been constituted a reception committee in behalf of the city. The tourists will be supplied with lunch boxes as they pass through.

What the Clubs Are Doing These Days

HUGUENOTS TO HAVE AUTOMOBILE CLUB

New Rochelle, N. Y., Aug. 16—The reasons for the organization of an automobile club are so explicitly and convincingly set forth in a letter issued in connection with the formation of a club in this place, that its reading may be beneficial in other cities where the same conditions exist, requiring the attention of automobilists.

Herewith is the call sent out by E. T. Birdsall, well known since the introduction of automobiling in this country:

New Rochelle, August 12, 1909.

HUGUENOT MOTOR CLUB

Dear Sir:

In consequence of the large number of automobiles owned in the City of New Rochelle and vicinity, and in view of the bad condition of the pavements of the streets and other conditions which make the operation of our cars more or less of a burden instead of a pleasure, it is believed that the time for the organization of a strong and influential motor club has arrived.

The benefits that can be secured by a strong and determined effort on the part of a club are many. Individual efforts, no matter how well directed or energetic, never have the weight of those of a well organized body. It is the old story of "United we stand, divided we fall," or, to fit this case, "United we win, divided we fall."

In addition to the material benefits there are those of a social, technical, and sporting character, interchange of ideas and experiences, legal help when in trouble, and many others that will at once suggest themselves.

It is proposed to begin in a small way at first, only expanding as the growth of the club warrants. Mount Vernon has a good club with a fine house. New Rochelle can surely do better.

With several hundred owners in the city we should be able to start with at least fifty charter members.

The meeting for organization will be held in the hall of the Republican Club on Church street, at 8 o'clock, P. M., Thursday, August 19.

If for any reason you cannot attend, drop me a line saying that you are in favor of the scheme and will join the club.

Don't put it off, do it now!

Yours very truly,
E. T. BIRDSALL.

SECOND LARGEST IN PENNSYLVANIA

Media, Pa., Aug. 2—The monthly report of President Weeks shows that the Automobile Club of Delaware County is now the second, numerically, in the State of Pennsylvania, having 357 names on its membership roll. The clubhouse bee is now buzzing loudly, and President Weeks has appointed a committee to decide on plans and select a site.

A touring information bureau has been established for the use of the members.

NORRISTOWNERS GIVE A TIME TO ORPHANS

Norristown, Pa., Aug. 16—One Friday recently four hundred little children of this town were given the time of their lives by the Norristown Automobile Club. Sixty-two cars were donated to the committee having the affair in charge. The little ones, after a 90-minute dash through the country to Willow Grove, reveled in the delights of that place for nearly three hours. After luncheon in the grove, and listening to Victor Herbert's orchestra, the tired but happy bunch of youngsters were whisked back to their homes in the evening.

ANNUAL RUN OF THE ROCHESTER CLUB

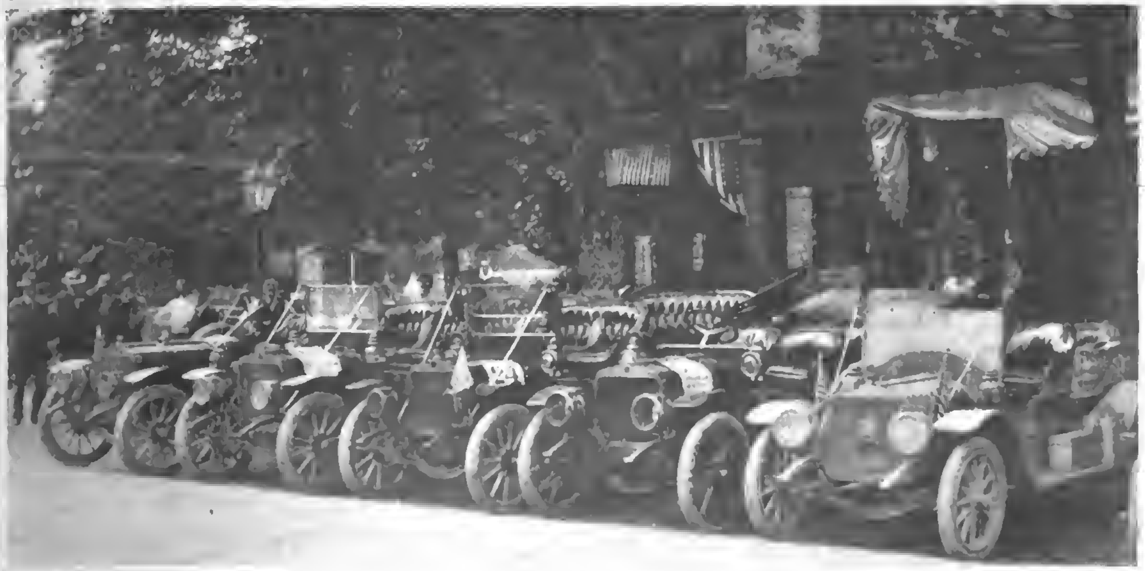
Rochester, N. Y., Aug. 16—Twenty or more automobiles turned out for the annual run of the local automobile club, and some three-score members had a most enjoyable outing. The run lasted a week, and took the participants through the lake region of central New York. Historic Watkins Glen and many other points of interest were visited. The photograph shows the cars parked at Lima, N. Y., and it will be noticed that the Seldens made in this city are much in evidence.

MACON, GA., OWNERS WANT A CLUB

Macon, Ga., Aug. 16—With over 250 automobile owners in this city, there is every probability that an automobile club will be formed at an early date. A number of the autoists have joined in a voluntary committee to secure an organization which will be a power locally for good roads. One man has offered a suitable tract of ground for a country clubhouse, about twelve miles out on one of the best roads.

CINCINNATI CLUB PLANS RACE MEET

Cincinnati, Aug. 16—There will be an auto day at Coney Island on August 22, when the Cincinnati Automobile Club will hold a series of track contests. The organization has started out to make this the biggest event of its kind on the local track, and five races are on the program. There will also be a chance given for dealers to exhibit the new models of cars and accessories.



Recent Run of the Rochester (N. Y.) Automobile Club, in Which the Local Made Selden Cars Were Much in Evidence

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

GROWTH IS A MATTER OF ROADS

The automobile being a pleasurable necessity, its use is made more general by the existence of good roads. But even with roads not deserving of the name, it is still a necessity. Hence its greater use is inevitable under any circumstances. With the knowledge that real roads breed automobile owners, it is wise foresight on the part of those interested in the progress of the industry to aid, as far as lies in their power, the building of roads and the betterment of those now reluctantly accepted as such.

When all interested in this enormous work are organized so as to concentrate their influence and votes, the rapidity with which the movement will go forward will be most surprising. The reason has its basis in the coming of the automobile, which continually advertises itself in abridging distances economically. The vehicle is available, but to make it available to the greatest economical extent it must have the right kind of a road over which to demonstrate its superiority over previous kinds of transport.

During the Glidden tour of this year, in crossing Iowa, one county, Greene by name, was discovered to have roads that compared favorably with many highways in Eastern States which began roadmaking ten years ago. Inquiry brought forth the fact that this roads interest had brought in its train an increase of fifty automobile owners in a town of twenty-five hundred inhabitants. Humboldt county, in the same State, called attention to its roads when the A.A.A tourists entered its confines. Previously in Wisconsin, not far from Madison, a town called Baraboo supplied roads built by itself, which were the joy of the trophy-chasers, who were perhaps too much inclined to rate the worth of a State, county, or township by the kind of roads supplied to the tour.

Michigan was put down as mostly absolutely bad; Illinois was only slightly sampled with indifferent results; Wisconsin did fairly well; Minnesota, not being tackled during the rainy season, escaped with some credit and more doubt as to what would have happened if a hard downpour had interposed; Iowa created some pleasurable surprise; not much was expected of Nebraska; Colorado is awakening in the matter of roads; and Kansas was passed through at a favorable season.

Some day there will be only one kind of traffic on the roads, and then they will not wear out so quickly. When the horse goes to his well-earned rest the motor-driven vehicle will have the road to itself; and it has been proven that a highway for autos exclusively does not succumb to traffic with any such rapid disintegration as does the present road harassed by two antagonistic forms of usage, the antiquated form of which is bound to disappear.

But the horse is certain to be with us for some time yet, and therefore it is up to our roadmakers to invent a highway that will better withstand the conditions under which it must labor in the next few years.

NEED OF ECONOMICAL OPERATION

Automobile manufacturers, in their desire to outstrip one another in offering the public models bigger and better than any ever before made, have too often lost sight of the fact that, after all, the most generally desirable feature of any car is economy. True, there are thousands of men who will pay any price for speed and appearance, and these have been most in evidence as buyers in the past; but there are thousands of men who must count their pennies, and these are the waiting buyers of the future. Perhaps a score of makers can find room for their product in the high-priced market; the great majority, however, must rely on the patronage of farmers and business men of moderate means.

Then there is that great branch of the automobile industry whose possibilities we have hardly begun to realize—the commercial vehicle. No one can doubt that the time will come when horses will not be allowed within the limits of large cities, much less be stabled there; automobile trucks and delivery wagons will handle everything, from the lightest to the heaviest traffic. In this field economy is the pre-eminent requirement.

The need of economy is the last and greatest, and perhaps the most difficult, of the problems which have confronted automobile designers. Power and endurance, in reasonable measure, have already been obtained. Even more than these, the question of economy is one that calls above all for skill in design. Much progress has already been made; the long-stroke motor and the use of anti-friction bearings and large wheels are important steps in advance. What steps yet remain we can but guess. The use of some cheaper fuel, possibly alcohol: the discovery of a substitute for rubber; perhaps, even, the turbine motor—all these the future may have in store for automobilists of the coming generation.

CONTAINED IN CONNECTICUT'S NEW AUTOMOBILE LAW

HARTFORD, CONN., Aug. 16—Nutmeg State automobilists and their touring visitors from other commonwealths are now subject to a new automobile law. An increased system of registration fees and a tax of $2 an each engine produced by manufacturer and tested upon the roads, are the chief alterations over the enactment now in force. The speed law and non-resident clause remain the same, the former requiring a speed reasonable with regard to traffic, and making 25 miles per hour, for one-eighth of a mile, evidence of reckless driving. Tourists are given ten days each year in which they may use the highways of the State without taking out a license. In spite of the influence brought to bear upon Governor Weeks by the Connecticut State Automobile Association and individual autoists, he signed the bill with certain amendments required.

Chief opposition was centered against the increased fees, which are considered burdensome. Otherwise the main points of the law are as before, such as prohibiting local ordinances except in parks, but inserting the 10-mile an hour provision in regard to streets of incorporated cities. The law also states that cars must not proceed at a speed faster than three miles an hour when approaching trolley cars which are receiving or discharging passengers on the same side. Governor Weeks desires that autos be required to stop on such occasions.

Classification will be by the A. L. A. M. formula in determining the horsepower of gasoline-driven cars, and manufacturers' catalogues in regard to steam and electric vehicles. A definite schedule has been set down, although the Governor desires a rate calculated at 60 cents per horsepower. The following is the list:

Cars of less than 20 horsepower, $6; 20 to 29 horsepower, inclusive, $10; 30 to 34 horsepower, $15; 35 to 39 horsepower, $20; 40 horsepower and over, $30; liverymen, each car, $10; trucks and other commercial vehicles, $5; motorcycles, $1; dealers, each car, $20; factory engines tested or operated upon the roads, each $2; operator's license, $2.

The registration fees for the cars expire on December 31 of each year, and the license for the individual on the last day of each February. The act goes into effect on September 1, but it is understood that those already having licenses and registration under the present law will not be required to take out new ones until the first of January.

Clauses have been introduced to prevent tampering with cars without the knowledge of the owners; and fines for anyone who operates while under the influence of liquor, for trying to make a record, or for racing. Sixteen years of age is set as the minimum for licenses, and the Secretary of the State has power to revoke licenses for reckless driving or other sufficient reasons.

On the whole, the law has many good points.

MASSACHUSETTS BUSY THIS WEEK TAKING ROAD CENSUS

BOSTON, Aug. 17—Beginning Sunday morning at 7 o'clock, and to continue this week, the Massachusetts Highway Commission is taking the most comprehensive road census ever undertaken in this country. The plans that have been made call for a count of the vehicles using the State roads for fourteen hours each day during the week at more than 200 stations scattered all over the State, with a twenty-four hour count at eleven places on the principal through routes of travel. This count, which is to be made in the period of heaviest tourist traffic, will be supplemented by another week's census in October.

From time to time in the office of the Highway Commission questions have arisen as to the relative amount of traffic on State roads in different sections, and its bearing on maintenance costs, and the commission never has had any accurate data upon which to base its estimates. In its announcement the commission says the road census is undertaken "first, to determine the relative importance of the different lines or routes of travel throughout the State," and "second, to secure at least a rough approximation of the relative use of such routes by motor vehicles and by horse-drawn vehicles."

The observers, principally boys and girls from the schools, were selected by the chief engineers of the five divisions into which the State roads were divided. They will be on duty every day from 7 a. m. until 9 p. m., and with the exception of motorcycles, bicycles, pedestrians and cattle, will make note of all traffic movements by their stations. They will be provided with cards for each day.

The stations at which a twenty-four hour watch will be made are on the roads between Boston and Lynn, Medford, Lawrence, Marlboro, Providence, Lowell, Lexington and Concord, Beverly and Gloucester, and Beverly and Newburyport. In addition an effort is being made to have simultaneous censuses taken by the Metropolitan Park Commission on Parkways in Revere, Saugus and Medford by the Boston Park Commission on Commonwealth avenue and by the Newton authorities on the Newton boulevard. If this is done some important results in the relation of traffic and cost of maintenance under different conditions are expected.

This is believed to be the first time a complete State road census has been undertaken in this country, and much valuable data not only for Massachusetts but other places is confidently expected to result from the count.

PLANS FOR LONG ISLAND MOTOR DERBY

NEW YORK, Aug. 16—Over on Long Island, and in the headquarters of the Motor Contest Association in this city, plans are maturing for the Long Island Motor Derby. This event is planned to take place September 21, over a 22-mile circuit having Riverhead and Mattituck as prominent points. Senator W. J. Grattan last week took Ralph DePalma over the course, and the well-known driver declared his belief that the roads would prove both fast and safe. As laid out at present, the route leads from Mattituck to Riverhead in a straight line, with one turn two miles from the latter place, so that there are two 10-mile stretches without a turn. There are but three deviations in the entire round, and none of these is bad as compared with most courses. Starting at Riverhead the towns passed through are Jamesport, Mattituck, Northville and Centerville.

GOOD ROADS NEAR NATIONAL CAPITAL

WASHINGTON, D. C., Aug. 14—As the result of a good roads rally in Alexandria, Va., Thursday night, the Alexandria-Washington Highway Association was formed for the purpose of securing the construction of a macadam road between the two cities. A tentative plan for the construction of the road, prepared by Charles H. Hoyt, a road engineer from the office of public roads, Department of Agriculture, was submitted. The meeting was attended by several hundred representative men of the two cities. About 25 cars took the Washington delegation over to George Washington's home city, and all who made the trip had a practical demonstration of the great need of improving the road connecting the two cities. The proposed improvement in this road will be the first step in the work of securing a boulevard between Washington and Mount Vernon.

JEWEL NOW CROXTON-KEETON COMPANY

Massillon, O., Aug. 16—The Jewel Motor Car Company, of this city, will in the future be known as the Croxton-Keeton Motor Company, with a capitalization increased from $250,000 to $500,000. H. A. Croxton, whose name now appears in the designation of the company, will continue in his former position of president and treasurer. He is also connected with the Massillon Iron & Steel Company, the Massillon Bridge & Structural Company and the Massillon Foundry & Machine Company, and has been designing and constructing machinery and machine tools for the past fifteen years. F. M. Keeton has been in the automobile business for ten years, serving in various capacities with the Pope-Toledo and De Luxe companies, and for the past two years has been making a close study of the taxicab situation.

For 1910 the Croxton-Keeton line will consist of eight models, built on three chassis of 30, 45 and 60 horse-power. The 45-horse-power cars will be practically duplicates of the two Jewel cars which passed creditably in the Glidden tour. The smaller chassis will be particularly adapted to town-car use, and may possibly be built as a taxicab.

The Croxton-Keeton Company will produce 600 cars in 1910. It has purchased the factory which it has leased for the past three years, and, although the capacity has already been doubled, is designing another additional building 160 by 380 feet, of saw-tooth construction. Work will be begun during the next month. The company has also secured an option on seven acres of ground across the street from the present factory for future enlargements. Distributing branches have already been established in New York, Pittsburgh, Pa., Cleveland, Chicago and Boston, and in the near future Minneapolis, Minn.; Kansas City, Mo.; Portland, Ore.; San Francisco, and Atlanta, Ga., will also be covered. The car made by the Croxton-Keeton Company will be known as the Croxton-Keeton, instead of the Jewel.

COMMERCIAL CARS USED IN INDIANAPOLIS

During the present season the commercial side of the automobile has been given much attention in Indianapolis, and it is estimated that 25 per cent. of the city's delivery work is accomplished by automobiles. Within the last few months the collection of milk by means of gasoline cars has gained great headway. One company is now operating two trucks in this work, covering the country within a radius of twenty miles. Much better time is made in this way than by the interurban cars. Another company operates a truck between Indianapolis and Plainfield, making one round trip a day. The route is through a rich farming district, and much milk and other produce is handled. Still a third line runs to Smith's Valley, Glenn Valley and Waverly.

AMERICAN SIMPLEX NEEDS MORE ROOM

Mishawaka, Ind., Aug. 16—The American Simplex Motor Car Company of this city has completed plans for a 172 by 240-foot addition to its plant, to be built of brick and concrete. The new structure will be a duplicate of the one at present occupied, thus doubling the capacity of the plant. This move was decided on at a recent meeting of the stockholders. Work will be rushed, as the additional space is badly needed to assist in putting out the cars which the company has already contracted to deliver. The design of the 1910 cars has been completed, and nearly the entire output has been disposed of to agents.

RIDER-LEWIS OCCUPIES NEW FACTORY

Anderson, Ind., Aug. 16—The Rider-Lewis Motor Car Company has occupied its new factory at this city and has begun to turn out its 1910 product, which was described recently in The Automobile. The first of the 1910 cars appeared in the streets within fifteen days after the occupation of the plant, and work will be continued in the same energetic way.

OAKLAND TO GREATLY INCREASE OUTPUT

Detroit, Aug. 16—The Oakland Motor Car Company, at Pontiac, is the latest to get caught in the wave of prosperity sweeping over the automobile industry. So great has been the demand for Oakland cars that announcement is made of changes whereby the company's manufacturing facilities will be increased to 12,000 cars a year. The property of the Pontiac Buggy Company has been acquired, and, in addition, several large buildings will be erected, giving a greatly increased capacity.

For 1910 the Oakland Motor Car Company will put on the market a new model, to be known as the Oakland "30." It will have a 100-inch wheelbase with a four-cylinder 4 by 4-inch motor, developing approximately 30 horsepower. The car will be made in two styles, touring car and runabout. The Oakland "40," which has proved so popular, will be continued, 3,000 of this style being manufactured in touring-car, runabout and toy-tonneau styles.

ALUMINUM COMPANY IN COMBINATION

Syracuse, N. Y., Aug. 16—One of the largest transactions ever made in a trade affecting the automobile industry has been executed by the Aluminum Castings Company. This concern has acquired the property and business of the following firms: The Allyne Brass Foundry Company of Ohio, the Allyne Brass Foundry Company of Michigan, the Allyne Brass Foundry Company of New York, the Syracuse Aluminum and Bronze Company, the Eclipse Foundry Company and the foundry department of the United States Aluminum Company. It is the announced intention of the Aluminum Castings Company to continue these plants under the present management and with the same attention to details as heretofore. They will be equipped with improved appliances, and particular attention will be paid to the scientific and technical features of the business.

OVERLAND MAKES A BIG AGENCY DEAL

Charles E. Riess & Son, of East Orange, N. J., signed an agreement last week to take the metropolitan agency for the Overland and Marion, and contracted for 1,500 cars for the coming year. The territory of the new agency will include Greater New York City and Long Island, extending as far north as Poughkeepsie. Salesrooms and a garage will be opened in the building at present occupied by the Stoddard-Dayton agency, at Broadway and Fifty-seventh street. Although a newcomer to automobile row, Mr. Riess has had the New Jersey agency for the Overland and Marion for the past two years. The Overland Company has already contracted with its agents for the delivery of 14,500 cars during 1910.

WINCHESTER ARMS CO. TO ENTER FIELD

New Haven, Conn., Aug. 16—With the enlargement of the charter of the Winchester Repeating Arms Company comes the announcement that the concern will soon enter the ranks of automobile manufacturers. It is expected that work in this direction will not be started much before the completion, within the next six months, of two large concrete buildings. Heretofore the charter of the company would not have permitted it to construct autos, but the legislature has removed the obstacles. In view of the Winchester Company's experience and reputation, further announcement of its plans will be awaited with interest.

WILL BRING OUT NEW GASOLINE MOTOR

South Bend, Ind., Aug. 16—At the annual meeting of the stockholders of the Wood Electric and Manufacturing Company the following officers were elected: W. E. Wood, president; D. M. Wood, vice-president; W. G. Crabill, secretary; C. H. Harper, treasurer. The company has perfected a gasoline motor that is attracting considerable attention and comment from the trade. The capital stock of the company has been increased to $50,000.

RIKER DISCUSSES TENDENCIES IN RACING AND DESIGN

BRIDGEPORT, CONN., Aug. 16—Automobile racing, tendencies in 1910 design, and constructive features of new models are pertinent subjects out at the big plant of the Locomobile Company of America. The cars for the approaching season are well under way, and the new buildings are now up to the second floor, so that before long a great increase in capacity will result. It is interesting to know the opinion of this concern in regard to the points chiefly concerning automobilists, as discussed by A. L. Riker, the chief engineer, and a well-known authority on these matters.

Mr Riker says: "It seems to us that automobile racing has had its day as far as manufacturers are concerned. The support of the makers is not likely to continue much longer, for the expense is too great and the returns often too small. The races have shown the makers how to build better, stronger, and, at the same time, lighter touring cars, and there seems to be little left to discover in that line. From a sporting standpoint it is likely that automobile racing will continue, as handled by promoters, for this manner of amusement is evidently very popular. Perhaps regular circuits will take the place of the present events here and there, aand those backing them will have several makes of cars. As to the action of the Locomobile Company with regard to the fall stock car races, it is problematical as to whether we shall enter, the matter has not been definitely decided one way or the other. Our inclination, however, is to withdraw from participation in the contests, as we see nothing to be gained by them, and they just upset factory routine.

There is really greater activity at present in engineering and constructive departments of the industry, and we are keeping in close touch with them. For instance, we have given considerable attention to the Knight motor, but I do not think that the sliding valve engine will revolutionize the tappet methods generally employed, at least at present. The new type has proven its efficiency in tests, but the life of an automobile motor must be long, and that is our aim with the tappet valve type. Another motor tendency which we have taken up thoroughly is that of the six-cylinder engine, but we have not found them necessary, or, indeed, they are at all superior to the four cylinders. It has been our experience that the six does not warrant its substitution for the four-cylinder type, especially when the engine is running over at a reasonable speed. Of course the six will pull more evenly on high at very low engine speeds, but with a well designed transmission, in regard to its ratios, there is no inconvenience in shifting. In fact, it has seemed that the necessity for shifting is less than the extra cost of maintenance and trouble to keep the car with the extra cylinders. At higher speeds we hold the four-cylinder preferable to the six or equal area.

"A most important feature of the industry lies in the commercial fields, and these lines are being seriously considered. The Locomobile Company has gone into the matter very deeply, for there are already a great many of our chassis used for business purposes, and in municipal fire and police departments. There is evidently a great future for this kind of motor-driven vehicle.

"I have noted with pleasure that there is a tendency among manufacturers at present towards longer stroke motors, for that is a type which we have advocated for a long while, at least for chain-driven cars. I believe, however, that the square cylinder is better for the shaft drive mechanism. In the latter case there is but a single reduction in gearing between the engine and the rear axle on high speed, that in the rear axle housing. Now, inasmuch as the housing must be made relatively small to give ample road clearance, it is evident that the bevel gear is rather small for the strain upon it, and the pinion is very small to give the required reduction. I think that with a long stroke engine the torque strains upon the gear teeth are greater than they should be subjected to, even with the use of strong alloy steels—that is, when the square motor of the same horsepower will give equal results with less strain. This can be proven mathematically and with the indicators.

"Our line for 1910 will show some refinements but almost no changes, and announcement of them will be made later."

The Locomobile Company has constructed nearly a thousand cars during the last season. At present it is working day and night, employing about 1,200 men in the two shifts, and still is shipping as fast as the cars can be completed and thoroughly tested. The new building, which is well under way, will give enough extra floor space to materially increase the output. It will be ready for occupancy by October 1. Then it is probable that architects will draw up plans for an extension of 300 feet to the main building, using some of the ground that has been reclaimed from the harbor flats. When this is completed, if the entire plant were on one floor it would cover a space 4000 feet long by 52 wide, according to Advertising Manager Kingman.

FIAT FACTORY ON THE HUDSON WILL BE UNIQUE

THE new plant of the Fiat Automobile Company, which is to be erected at Fairview, just outside of Poughkeepsie, N. Y., will embody many European ideas, and will resemble in many respects the present Fiat factory at Turin, Italy. It is needless to state that the Italian style of architecture will be employed; special consideration will be given to the harmonizing of the building with its background, which is one of the most picturesque spots along the Hudson River.

It has not been decided whether steel and brick or reinforced concrete will be used, but the general layout will be along the lines of the best practice in factory construction. One of the distinguishing features will be the tower, 105 feet high, centrally located on the main building, which will contain all the offices and draughting rooms. This will be a point of attraction to boats plying the Hudson and to trains passing on either the West Shore or the New York Central tracks.

The main building will be 363 by 140 feet. The first floor is to be used as a machine shop and assembling hall; the second floor will be for machines of a lighter character and the third floor for wood-working. The ceilings are high, and the side walls consist principally of immense windows, giving ample light and ventilation. From the main building extend a series of one-story wings 70 by 140 feet, five in number.

The future extension of the factory has also been taken into consideration. It is generally to be noted that factories are constructed for immediate requirements only, and when any extensions are necessary there results a conglomerate mass of buildings with no architectural connection. For the Fiat plant, however, extensions have already been designed in conformity with the style of architecture which will fit properly in the general scheme of construction.

Full attention has been given to all the practical requirements of factory design, especially with regard to sanitation and ventilation. An elaborate stand-pipe and sprinkler system will make the fire risk a minimum. Electricity will be the motive power. The high voltage of the alternating system will be transformed into low-voltage direct current, thereby making the power which is placed in the workman's hands perfectly safe.

The exterior of the building will be treated in light stucco, with roofs of red terra-cotta tile.

SOME LATE NEWS FROM TIREVILLE

Akron, O., Aug. 14—The plant of the Buckeye Rubber Company, with the exception of the vulcanizing and finishing departments, was destroyed by fire this week. The loss has been estimated between $100,000 and $150,000, according to General Manager S. S. Miller, all covered by insurance. The main building, which was destroyed, contained the offices of the Buckeye Company, the manufacturere of Kelly-Springfield tires, and of the Consolidated Rubber Tire Company, of New York, the selling agent. The plant was working overtime to fill orders, and the officers announce that arrangements will be made to fill the accounts with little delay. The factory will be rebuilt.

Two new concerns have recently been organized and are beginning operations. The Akron Pneumatic Tire Making Company is manufacturing machines for stretching the fabric in the formation of the tires, and will either lease the machines or sell the rights on a royalty basis. The officers of the firm are: President, Charles A. Ley; vice-president, M. B. Kuhlke; secretary and general manager, James W. Meeker; and the officers, with E. T. Willams and H. C. Squires, form the directorate. The machine was invented by Mr. Squires and Mr. Meeker. The other newcomer is the Fall Rubber Company, of Cuyahoga Falls, which will produce automobile and buggy tires.

The annual picnic of the B. F. Goodrich Company was an immense affair, over 15,000 people attending. The company spent over $4,000 to make the affair a success, and was amply rewarded by the enjoyment of its employees and their numerous friends.

PIERCE BRANCH FOR TOURISTS ABROAD

Paris, Aug. 12—The Pierce-Arrow Motor Car Company's branch has recently been transferred to 22 Avenue de la Grande Armée, where much better accommodations are available. The change was made necessary by the constantly increasing numbers of Pierce owners who tour abroad every year and make their headquarters here. The branch was originally established for the purpose of providing parts for Pierce cars used abroad, so that the owners might not be forced, in case of accident, to wait for a shipment from the factory. However, the establishment of the agency soon caused many owners who previously had rented cars in Europe to take their own cars with them, feeling secure in the knowledge that they could obtain spare parts as quickly as if they were using foreign cars. Since the early days the scope of the branch has grown until now it acts almost primarily as a bureau of information for Pierce owners and as an agent for them in the many formalities of entering cars, becoming a member of touring clubs, securing licenses and obtaining correct and detailed information regarding routes. Complete data can thus be obtained before sailing.

ATLANTA TO NEW YORK IN NINE DAYS

First to test the new touring route between New York and Atlanta, Ga., was R. E. O'Donnelly of the latter city, who arrived in the metropolis one morning last week in his Packard car after nine days on the road. He reports the journey a most delightful one. Mr. O'Donnelly's experience is especially interesting, as it demonstrates the practicability of the route for the ordinary tourist. For the first four days out of Atlanta it rained almost constantly, and the Southern roads, which are mostly of dirt or clay, became at times axle-deep in mud; but in spite of this handicap the party had no difficulty in making the thousand-mile trip in about seven days' actual running. Half a day was taken to enjoy the beauties of Roanoke and the Natural Bridge, Va., and another for the run to Gettysburg. The worst roads of the journey were encountered between Rock Mount, Va., and Greensboro, N. C., and between Greensboro and Salisbury, N. C. These could probably have been avoided by a cut-off through Winston-Salem, N. C.

The trip was made in Mr. O'Donnelly's 1908 Packard "30," which already had about 2,800 miles of touring to its credit. The car was driven hy T. B. Dial, and came through without any troubles except a few punctures incident to the rough roads.

"MILTOUN" APPOINTED U. S. CONSUL

Francis Miltoun Mansfield is the complete name of the facile writer who has contributed such interesting European touring stories to the columns of The Automobile. Mr. Mansfield has been appointed consul for the United States at Toulon, which is France's greatest marine arsenal.

American manufacturers who are looking for a foreign source of distribution can make an effort in that direction by sending catalogues to Mr. Mansfield, who will be pleased to keep a quantity on file. Incidentally, autoists touring in that part of France will be able to obtain timely information by calling upon Mr. Mansfield at the American consular agency in Toulon.

FOR TOURISTS IN CENTRAL NEW YORK

Buffalo, N. Y., Aug. 16—The touring department of the Automobile Club of Buffalo says that owing to the building of new roads between Avon, Geneseo and Mount Morris the regular route to Elmira is closed to traffic. The most satisfactory way at present is to take the Big Tree road from Batavia, through East Bethany and Peoria to Mount Morris, and thence to Danville by taking the splendid road past Craig Colony. The road from Geneseo Village to the cross-roads leading to Mount Morris and Groveland is closed, and the road further up the hill should be taken.

Newly Located Paris Branch of the Pierce-Arrow Motor Car Company—Foreign Headquarters for Pierce-Owning Tourists

CONCERNING CASTOR OIL LUBRICATION

Editor THE AUTOMOBILE:

In a recent issue of "The Automobile" a question was asked regarding the advisability of using castor oil for lubricating the cylinders of high-speed gasoline engines, and it was somewhat surprising to learn that such use of castor oil is considered the very highest practice.

It is not exactly clear upon what such a claim is based. The best lubricant to meet the severe conditions found in a combustion motor is one that in addition to being unctuous to a high degree does not possess more body than is consistent with fluidity; is free from any tendency to oxidize or gum; is free from acids or other corrosive ingredients and which has a high temperature of vaporization. Now, a vegetable oil does not satisfy these requirements, and castor oil is a vegetable oil. Brannt states: "By long exposure to the air castor oil becomes thick and forms a viscous mass, and even acquires poisonous qualities." Castor oil has a high viscosity and specific gravity and contains from 7 to 14 per cent of free, fatty acids. If admitted into the combustion chamber glycerine and fatty acids would be formed by the decomposition of the oil at the high temperature encountered and a heavy carbon deposit would be left behind.

This much has been acknowledged by even the most enthusiastic friends of castor oil and they admit that this oil gives the best results only in cylinders in which the pistons and piston rings fit unusually tight. For it cannot be denied that castor oil is poor stuff to be found in a combustion chamber, and therefore should not be allowed to pass the piston.

Since it is practically impossible to make rings so tight but that some oil will get by them into the combustion chamber, glycerine and fatty acids will be formed as pointed out above and an undue amount of carbon will be deposited. If the oil is not allowed to pass the piston rings the head end of the cylinder will of necessity be insufficiently lubricated. In any case its use would seem to be a choice between two evils.

Most authorities favor a light mineral oil for the lubrication of internal combustion motors. Castor oil may be satisfactory in some special cases, but any temporary results which could be obtained by the use of castor oil would be accomplished by flake graphite, by putting the graphite into the crankcase mixed with oil in the proportion of a teaspoonful of graphite in a pint, or by removing the spark plug and squirting a little graphite through the opening by means of an insect gun. By its use lasting results would be obtained instead of a merely temporary effect.

The function of flake graphite is to form a smooth, veneer-like coating over all bearing surfaces with which it comes in contact. It is therefore possible to not only use a lighter oil, but less of it, and should for any reason the oil supply fail there is always the assurance that the parts may run for a long time without serious cutting or bound pistons. By the use of graphite a higher compression is obtained, the engine runs easier and more power is available.

JOSEPH DIXON CRUCIBLE COMPANY,

Jersey City, N. J. L. W. Brooks.

GROSSE POINTE TRACK FOR CHALMERS

DETROIT, MICH., Aug. 16—When the work now under way is completed, the Chalmers-Detroit contest department will have facilities superior to any other automobile concern in the country, if not in the world. Just to the east of the Chalmers plant is the old Grosse Pointe track, known as the scene of some of the most famous trotting and pacing events in the annals of the harness world. A few years ago the track was sold to a western syndicate which purposed holding running meets, with bookmaking as the big feature. The Michigan law put a crimp in the plan and the track fell into disuse with the advent of the State Fair Ground course. Now the Chalmers-Detroit racing crews have been established in commodious quarters at the Grosse Pointe track, and where once the steppers held full sway, the bark of open ports and the whirr of automobiles clipping seconds off records on the fast mile track, furnish a new diversion.

CONNECTICUT'S TOLL BRIDGE FREED

HARTFORD, CONN., Aug. 16—The one remaining toll bridge across the Connecticut River in this State, that at Thompsonville, has been opened to free use. The stockholders accepted the offer made by the State for the structure, and the event was duly clebrated. Representative H. R. Coffin, known as the father of the free-bridge idea, was the first to cross in an automobile, using his 29-horsepower Columbia.

Where Packard Ignition Cable is Made at Warren, O.

PLANT OF PACKARD ELECTRIC COMPANY

WARREN, O., Aug. 16—One of the largest and most substantial factory buildings in this city is the plant of the Packard Electric Company, the well-known manufacturers of ignition cable and other automobile accessories. The latest addition to this plant is the two-story brick building shown in the illustration. Part of the floor space is devoted to offices, part to the company's transformer department, and the rest to insulating and ignition materials. This cable has been on the market for the last eight years and has made an enviable reputation for itself. Its increasing popularity has necessitated doubling the capacity of the plant three separate times. The accompanying bird's-eye view shows the plant as it stands to-day.

SPOONER TO BE A PARTIAL DETROITER

DETROIT, MICH., Aug. 16—The biggest automobile colony in the world has received another accession of note, F. Ed. Spooner, veteran auto photographer, having decided to open an office in Detroit. Spooner will take personal charge of the local office, his partner, Wells, remaining in New York. The matter of location has not been determined, Spooner at present being quartered at the Pontchartrain. The local field has long been regarded as good picking by those in touch with the situation, owing to the great number of factories and the constant demand for fast camera work. Local men who failed to cultivate the business will now probably have occasion to repent at leisure.

AUTO FIRE ENGINES FOR BALTIMORE

BALTIMORE, Aug. 16—Chief Horton, of the Baltimore Fire Department, has recommended the use of horseless fire engines for the suburban sections of the city, with the result that two of these will be placed in commission in the fall as a test. If they work as expected, several more will be ordered. The Chief thinks they are just the thing for fighting fires in the outlying districts. He asserted, however, that as yet these machines have not yet developed enough power for practical fire work in the congested business districts.

ONE-LUNGER DISPLACED TWO-LUNGER

ATLANTIC CITY., Aug. 16—Charles Hinckleman, the local agent, some time ago closed a deal with the post office people here to put a little "one-lunger" Brush on the job of collecting and delivering mail. The bustling little car has been at work for over a week and has been making good with a vengeance, the former horse-drawn rig being miserably slow and inefficient in comparison.

MOTOR TRUCK CARRIES REVIVALISTS

WILMINGTON, DEL., Aug. 16—A large and heavy motor truck, used by the Charles Werner Company in the delivery of coal, has been pressed into service as a passenger-carrying vehicle between Wilmington and Brandywine Summit campmeeting, a distance of eight miles, and is making several round trips each day. The car has been provided with comfortable seats and a cover.

On a New Jersey Automobile and Motor Club Run in Midsummer

New Types of Storage Battery—The Westinghouse Storage Battery Company, which was incorporated July 12, has acquired all the plant, patents and equipment of the storage battery department of the Westinghouse Machine Company and of the General Storage Battery Company, and will manufacture, at Boonton, N. J., both the Westinghouse and Bijur types of batteries for those classes of service in which each has proven superior. The Westinghouse Company enters the field with greatly increased manufacturing facilities and the best engineering talent available, and will maintain thoroughly equipped testing laboratories to insure uniformity of materials and product.

Why Name Has Been Changed—The Thermoid Rubber Company explains that it changed its name from the Trenton Rubber Manufacturing Company in order to avoid confusion in the trade. Thermoid brake lining, such as this company has made for some years, has brought it into prominence, not in the automobile business alone, but in almost every business in which friction materials find a use. The Thermoid Company attributes this popularity both to the merit of its product and to the fact that the company has never made a claim for it which was not based on fact.

Auto Show Near New York—An automobile exhibit will be one of the features of the Queens-Nassau Fair at Mineola, L. I., to be held September 21-25. The fair is within a stone's throw of Krug's corner, made famous by the Vanderbilt races, and but 20 miles distant from New York via the Queensboro Bridge. Manufacturers and agents who wish to exhibit may make application to C. G. Miller, Hempstead, L. I. The fair is largely attended by automobile owners, and there are miles of good Long Island roads on which to demonstrate cars.

Motor Buggy Champions—The Holsman buggy again won its class in the Algonquin hill-climb this year, and the Holsman Company says that it was the only car competing that negotiated Perry Hill from a standing start entirely on high gear. The Holsmans were equipped with their special four-cylinder all-ball-and-roller-bearing motor, the only one, so far as is known, in existence, and its success demonstrates its utility.

Atlas Taxis for New York—The Atlas Motor Car Company, of Springfield, Mass., has just received an order from the Kayton Taxicar & Garage Company, of New York City, for 40 taxicabs, in addition to the 26 already in use by that company. If this order is shipped complete by October 15 it will be followed by another order for 34, completing an even hundred Atlas cabs for this one New York company.

Black Company Buys Crow Output—The Black Manufacturing Company of Chicago, makers of the Black high-wheeled automobiles, has arranged to market the entire output of the Crow Motor Car Company. The latter concern is a new one, located at Elkhart, Ind., and its first machine made its appearance a few days ago.

Another Win on New Departure Bearings—The Apperson Jack Rabbit which won the recent 202-mile road race at Santa Monica, Cal., was mounted upon New Departure ball bearings. This car established a new American record, its average time over the 8.4-mile course being 64.45 miles per hour, as against the 64.3 in the last Vanderbilt.

Enlargement for Thomas Factory—The E. R. Thomas Motor Company has arranged for a large addition to its factory in Buffalo. A two-story building 104 by 167 feet will be erected at a cost of about $16,000.

Bosch Magnetos for Winton Cars—Announcement has been made that the new Winton cars will have Bosch magnetos as equipment.

IN AND ABOUT THE AGENCIES

Grabowsky, California—A representative of the Grabowsky Power Wagon Company, of Detroit, who recently made a trip alon gthe Pacific Coast, made agency arrangements with Hawley, King & Company, of Los Angeles, Cal., and with Waterman Brothers & Company, of Fresno, Cal.

Walden W. Shaw Company, Chicago—The Walden W. Shaw Company has given up the agency for Thomas cars and will in the future handle the imported Berliet and the Columbia electric.

Haynes, St. Louis—The Haynes Automobile Company of Missouri has temporarily located at 4530 Delmar avenue.

RECENT BUSINESS CHANGES

Banker Brothers' Company Changes Name—The old Banker Brothers' Company, which has been a pioneer in automobile matters in Pennsylvania, now located at Pittsburgh, will hereafter be known as the Pioneer Motor Car Company. The officials will be the same as previously and the cars handled will be the Chalmers-Detroit, Hudson and Lozier.

Queen City Garage, Battle Creek, Mich.—Don Cole, who has for some time been connected with the Olds Motor Works, of Lansing, has purchased a half interest in the Queen City Garage, of Battle Creek. A partnership has been formed with F. W. Ellis, the former proprietor. The agency for the Jackson will be continued and a repair department added.

Ajax Expansion—To accommodate a great increase in business the Ajax-Grieb Rubber Company has moved its executive offices from Broadway and Fifty-seventh street, New York, to a large suite in the Thoroughfare Building across the way. The former offices will be a New York salesroom. A new three-story building is being added to the Trenton factory.

Meridan Place Garage, Indianapolis, Ind.—The Meridan Place Garage, recently opened at Meridan Place and Twenty-second street, has been purchased by A. W. Allison and A. L. Duggan from its builder, J. C. Lazarus. In the future it will be known as the Twenty-second Street Garage.

PERSONAL TRADE MENTION

Lewis M. Crittsinger has joined the R. L. Morgan Company, of Worcester, Mass., as purchasing agent. Mr. Crittsinger is one of the youngest and at the same time best-known men in the trade, and to take up his work with the Morgan Company resigned from the Chalmers-Detroit Motor Company. He has also been connected at times with the purchasing departments of the E. R. Thomas Motor Company, of Buffalo, and the Ford Motor Company, of Detroit.

Lewis M. Crittsinger

Fred C. VanDerhoof has been appointed manager of the Olds Motor Works Branch in Philadelphia, handling the Oldsmobile and the Oakland, both products of the General Motors Company. Mr. VanDerhoof is one of the best-known men in the industry, having been associated with it for a number of years, first in the branch department of the Ford Company, and then with the Bergdoll Company in the Quaker City. He managed the Ford branch in that city for several years and was general manager of the Bergdoll Company when it had the agency for the Chalmers-Detroit, Thomas and a number of other makes. He has already taken charge of the Olds branch house in Philadelphia and will have an extensive territory along the Atlantic coast to the South.

R. B. Van Dyke has been appointed manager of sales of the automobile department of the American Locomotive Company. Mr. Van Dyke has been with the company for a number of years and with the automobile department since its inception. His headquarters will be at the New York office, 1886 Broadway.

Frank H. Bowen has joined the sales force of the Simplex Automobile Company at the new headquarters, 1860 Broadway, New York City. Mr. Bowen has been connected with the automobile trade for eight years and was recently with the Harry S. Houpt Company in selling Thomas cars.

P. C. Chrysler has been appointed manager of the new Chicago branch of the General Vehicle Company, of Long Island City, N. Y. He will be remembered as formerly connected with the Rainier and American Locomotive.

R. S. Ireland has been appointed sales manager of the Ajax-Grieb Rubber Company and will be hereafter responsible for the distribution of Ajax tires. He was formerly Eastern sales manager of the company.

C. E. Reddif has been appointed designer of the Columbia Motor Car Company. Mr. Reddif served in a similar capacity for the Electric Vehicle Co.

P. A. Williams, Jr., sales manager of the Atlas Motor Car Company, started August 17 for an extensive visit to Bermuda.

OBITUARY

Arthur E. Adams, manager of the Algonquin Motor Car Company of Boston, died in that city on August 11. Mr. Adams was well known throughout the automobile trade, for he had been associated with it for many years, starting with the Mobile Company in 1899. Some years later he went to Boston with the Pope branch and at times was associated with agencies until he took hold of the Algonquin Company, the agent for the Oldsmobile. A large delegation of the trade attended the services on Saturday.

TAXICAB AND TRANSIT

Lebanon, Ky.—Great success has attended the new automobile stage line between this place and Springfield. The distance is 20 miles, but the train connections are so roundabout and infrequent that nearly a day is necessary to go between the points by rail. Two automobiles have been purchased—one for reserve—and two round trips are made daily, one in the morning and the other in the afternoon. The car has been full on each run so far. Louisville capital is behind the enterprise, and other lines are contemplated where necessary.

Washington, D. C.—Rock Creek Park will probably be opened to a line of buses to make access to the grounds easier. One of the capital sightseeing companies has asked for permission to operate six machines, with a seating capacity of from 30 to 40 persons, on a regular schedule from the traction terminals. They would run on a two or three-mile circuit, tapping convenient points, and a 10-cent round-trip fare, with stop-over privilege, is planned.

WHITE IN MILITARY MANEUVERS

BOSTON, Aug. 16—White steamers are playing a prominent part in the military maneuvers this week. First of all, a White car is being used by General Wood, who is the umpire in the big war game which is being played between the Massachusetts militia, on the one side, and detachments from the National Guards of New York, Connecticut and the District of Columbia, on the other side. In addition, three White Steamers are attached to the headquarters of General Brigham, who commands the Massachusetts troops, and is in charge of the "defense" of Boston. Furthermore, the White ambulance, belonging to the Massachusetts National Guard, will be in active service, as will the White car of Quartermaster Sergeant Hathaway. The latter car will be run on kerosene and will be used in traveling about the powder magazines and other places where the military regulations prohibit the storing of gasoline in any shape or form. Finally, Colonel George Harvey, editor of *Harper's Weekly*, has sent his White touring car to the front for the use of the war correspondents and photographers assigned to cover the maneuvers for his paper.

NEW AGENCIES ESTABLISHED

Overland and Marion: New York—Charles E. Riess & Son, East Orange, territory including New York, Brooklyn, Long Island, Staten Island and as far north as Poughkeepsie. Quarters secured at Broadway and Fifty-seventh street.

Studebaker: Trenton, N. J.—C. P. Weeden, the Valentine-Weeden Company, 432-438 Princeton avenue. Including Studebaker-E-M-F and Studebaker-Flanders 20

Detroit Electric: Nashville, Tenn.—Southern Electric Car Company, temporarily located with the Tennessee Automobile Company.

Hupmobile: Atlanta, Ga.—E. D. Crane & Company, for the northern district of the State, in addition to the Regal.

Oldsmobile and Oakland: Wilmington, Del.—Pennsylvania Garage, Pennsylvania avenue and Clayton street.

Reo: Houston, Tex.—Guilliaumo Auto Company, 707 Rush avenue, for South and East Texas.

Chase: Cleveland—E. P. McGollier, 1926 Euclid avenue.

Hupmobile: Louisville, Ky.—Fulton Mandeville.

Oakland: Philadelphia—Fred C. VanDerhoof.

Lozier: Trenton, N. J.—J. B. Gundling.

RECENT INCORPORATIONS

International Aerial Navigation Company, Galveston, Tex.—Capital $1,000,000. To establish airship service for freight and passengers to all parts of the United States, Mexico and other countries. President, Dr. F. J. Field; treasurer, Dr. Fred Terrell; secretary, V. P. Brown. To use 12-passenger machines, constructed in St. Louis, beginning operations on January 1, 1910.

Falls City Automobile & Garage Company, Louisville, Ky.—Capital $50,000. To act as wholesale and retail traders in automobiles, motorcycles and other vehicles and to operate garage and repair shop. Incorporators: W. J. Day, H. J. Hogan, H. C. Shanks, B. B. Bales.

Husson Motor Company of America, New York—Capital $12,000. To manufacture gas engines, motors, machines, automobiles, aerial vehicles, motor boats, etc. Incorporators: John Husson, J. J. Hogan, W. E. Young.

Tygard Engine Company, Plainfield, N. J.—Capital $250,000. To manufacture Tygard engine, automobiles, carriages, etc.; Incorporators: G. M. Neagley, W. E. Buhl, F. C. Tygard, E. E. Tygard, A. F. Randolph.

C. F. Splitdorf, New York—Capital $500,000. To manufacture electrical machinery, ignition apparatus, automobile parts and sundries. Incorporators: Charles F. Splitdorf, John Splitdorf, P. J. W. Kelley.

Linkroum Automobile Company, Newark, N. J.—Capital $20,000. To manufacture and deal in automobiles, motors, etc. Incorporators: Courtlandt Linkroum, William H. Linkroum, C. R. Erith.

Instantaneous Lighter Company, Columbus, O.—Capital $30,000. To manufacture automatic lamp lighters for automobiles and other purposes. President, F. C. Barger; treasurer, L. B. Barger.

Automobile Rim Securities Company, New York—Capital $150,000. To manufacture automobile and vehicle parts and accessories. Incorporators: Henry W. Goddard, Robert H. Gay, Edward Weck.

Essex County Overland Company, Newark, N. J.—Capital $100,000 To manufacture and deal in automobiles and motorcycles. Incorporators: L. F. Crocker, R. D. Crocker, H. H. Poole.

Union Motor Car Company, Newark, N. J.—Capital $125,000. To manufacture automobiles, locomotives, etc. Incorporators: P. Broderson, A. Broderson, F. C. Stowers.

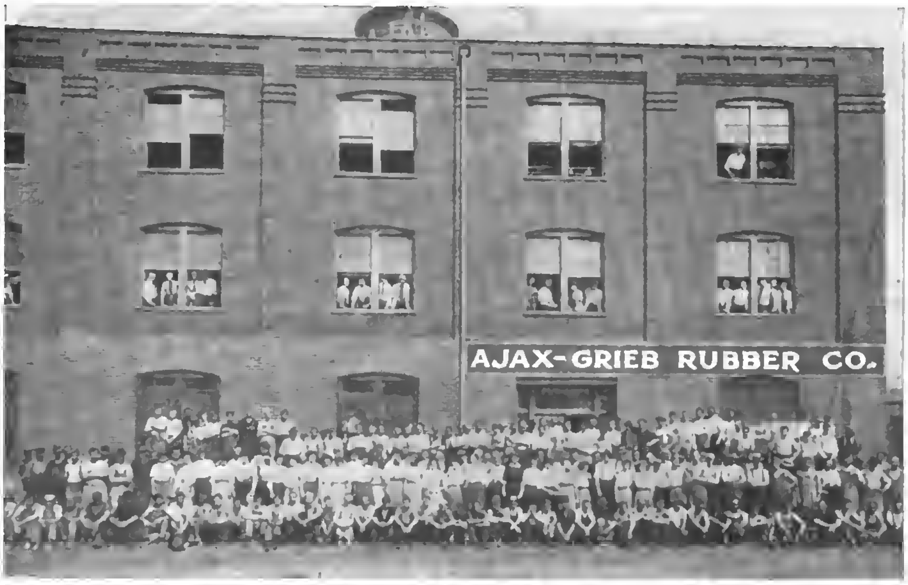
Pope-Hartford Company, Newark, N. J.—Capital $30,000. To manufacture and deal in automobiles. Incorporators: C. C. Pilgrim, Mary E. Lane, J. M. Hulbert.

Hall Car Company, New York—Capital $20,000. To manufacture engines, cars, locomotives and vehicles. Incorporators: T. M. May, B. H. Howell, H. P. Hall.

Metz Company, Waltham, Mass.—Capital $500,000. To deal in automobiles. President, J. C. Robbins; treasurer, C. J. Spiegleberg.

Continental Motor Manufacturing Company, Muskegon, Mich.—Capital increased from $225,000 to $500,000.

Trackless Trolley Company, New York—Capital $150,000. C. E. Barrett, A. L. Newman.



Factory Forces of the Ajax-Grieb Rubber Company, Trenton, N. J.

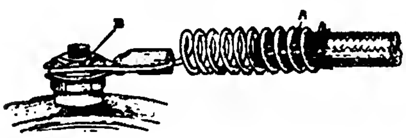
Information for Auto Users

"Red Rib" Ignition Cable—Accessory jobbers and dealers are pleased to find that the "Red Rib," which has been so cleverly advertised with a running fire of questions in the trade journals during the last few weeks, has turned out to be a line of popular-priced ignition cable of American manufacture. The cable will be handled by the National Sales Corporation of New York, which also originated the "Red Head" spark plug, and is noted for the quality of its products as well as of its advertising. The company will endeavor to minimize the selling and distributing expenses incidental to the launching of a new article, and maintain a schedule of popular prices. The cable will be made with both rubber and braided insulation, in primary and secondary and all intermediate sizes. Both the rubber and braided types will be listed at the same price, as it is the intention to simplify this business, as was done with the "Red Head" spark plug. A high standard of manufacture has been set and the cable had to undergo severe tests under the eyes of ignition experts before receiving the final approval.

A New Idea in Terminals—A terminal for the prevention of trouble as caused by a broken electrical circuit has been brought out by Read, 37 Kingston avenue, Brooklyn, N. Y. This is not only useful as a preventive of trouble along this line, but where used with a spark plug or other binding post, having nuts to screw on or off, it forms an efficient nut lock as well. In substance, it is sim-

READ TERMINAL HAS AN EXTRA WIRE

ple in the extreme, being merely a coil of brass wire soldered with the ordinary terminal end of copper. This coil of wire may, however, have one or two diameters, according as it is intended for use with small primary wires or large secondaries. In addition, there is soldered in another short piece of wire, which is bent over and lays flat parallel to and about 1-16 inch above the copper terminal. It is this latter portion that forms the nut lock, or it may be used as the connection proper, when the spark



SHOWING HOW THE LOCK WORKS

plug binding post has a hole through it, the wire slipping through this hole.

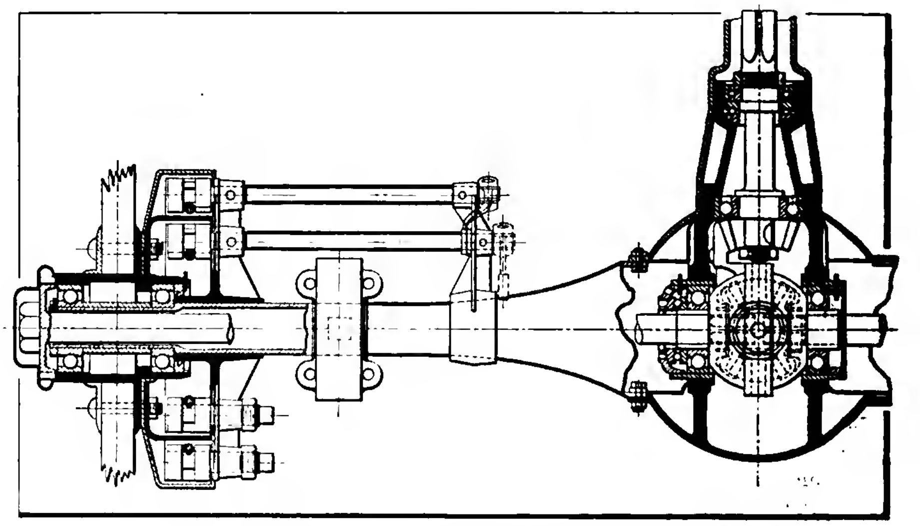
To connect these spring terminals to the wires, the insulation is cut away for half an inch, and the fine wires spread out and turned back over the outside all around. The terminal is then jammed or screwed on over this, the contact being sufficient. The coil of wire will absorb all vibration, so that with this device the danger of broken circuits due to this cause is eliminated.

Kurtz Alternating-Current Magneto—The Hercules Electric Company, of Indianapolis, already favorably known through its direct-current magnetos for stationary engine use, has brought out an alternating-current machine of the usual type for automobile use. For this

KURTZ MAGNETO IS LOW TENSION USED WITH SEPARATE COIL

purpose the company selected as the most desirable the low-tension design with separate coil, which allows ample space for insulation of the high-tension winding and also permits the use of a battery circuit through the same coil and distributor. Much attention has been given to the design, with the view of having the necessary functions carried out by the fewest and simplest parts. It is stated that the total number of parts is one-third less than on most magnetos. At the same time there is nothing freakish in the construction. The entire circuit-breaker box may be removed by simply releasing a spring with the fingers, no wrench or screw-driver being required. The points of the contact-breaker can be adjusted with a nail or bit of wire. The points are of iridium-platinum. Heavy bronze bearings are used, and insulation of the best vulcanized rubber. All gears are enclosed and practically noiseless. The magneto frame is cast in a solid piece, and the pole pieces are riveted in, making a construction extremely strong and adapted to stand excessive jarring and vibration. The magneto was thoroughly tested before being offered to the trade, and the Hercules Company feels that it will prove a worthy member of the Kurtz line.

Attractive Live-Axle Design—A live rear axle which embodies several good features and shows evidence of careful designing has been brought out by the McCue Company, of Hartford, Conn., and is illustrated in the accompanying line drawing. The axle proper is of pressed steel welded laterally, with openings front and back. Apparently the two halves of the axle are exactly alike; this, of course, greatly simplifies the manufacturing. The propeller shaft is designed to be of the one-joint type, enclosed in the torsion tube; the rear end of this tube is expanded and bolts over the front opening in the axle, and the front end carries a forged steel yoke, to be hinged to the cross member of the frame. Thus none of the torsion strains are carried by the universal joint. The differential and bevel gear and pinion are carried on a frame inserted through the rear opening of the axle. The axle shafts are full floating, with hub clutches integral. Annular ball-bearings of ample size are used throughout, with separate self-seating thrust bearings. The spring seats may be made either to key on or to swivel. The rear hubs carry two sets of brakes, both internal expanding, on concentric drums of ten and fourteen inches diameter, respectively. The brakes are operated by means of camshafts, easily adjustable, and these are extended so as to bring the brake connections inside the frame. The axle is made in two sizes, for cars above and below 2,500 pounds weight. The design is very attractive and the manufacturers state that they use only the best materials.



EXCELLENT DESIGNING IS AT ONCE APPARENT IN NEW MCCUE REAR AXLE

VOL. XXI NEW YORK—THURSDAY, AUGUST 26, 1909—CHICAGO No. 9

THE AUTOMOBILE

INDIANA SPEEDWAY PREMATURELY OPENED

WITH A DEPRESSING FATALITY LIST

INDIANAPOLIS, Aug. 23—The plain facts of the case are that the Indianapolis Motor Speedway was opened before completion—such completion as meant safety to those participating in the contests and safety to those who watched the racing. The management had entered into a double contract, one with the entrants and the other with the public, to open the speedway on August 19, 20, and 21. Only through almost superhuman exertion was it possible Thursday during the noon hour to start the first race and thus fulfill the announced obligations. There were the impatient drivers and the insistent spectators, the former ready to respond to the starter's pistol and the latter eagerly surging through the gates, anxious not to miss the opening event.

Certainly the drivers knew that the course had not received anywhere near its finishing touches, but while a few were questioning the advisability of competing, the greater number had no contrary thoughts and seemed unduly exercised in wanting the races to begin. Chances were numerous that accidents would punctuate the sport; and accidents marred the opening day in the form of a double fatality, Bourque and Holcomb of the Knox team being the sacrifices to the god of sport. Opinions are not in accord as to the exact cause of this catastrophe, but a ditch and a tile-strewn stretch of ground supplied conditions which added to the fearfulness of the happening. Some have it that Bourque must have been physically exhausted, for it is known that he had not been feeling over well. The distance of the race on such a course was too much for a single driver, unless endowed with extraordinary powers of endurance. Furthermore, as the race progressed. the surface of the track disintegrated and added to

The Crowded Grand Stand Attested the Interest Taken by the Public in the Contests—Finish of Friday's 50-M

the difficulties of the task. Built at high speed, the work could not be done with the thoroughness requisite to insure a reasonable degree of permanency in the track's surface.

Friday the thousands came again, and there was a feeling of decided relief when the sport concluded without any additions to the killed and injured list. Perhaps some were disappointed.

But Saturday supplied a distressing culmination, when in one accident mechanician Kellum and two spectators were killed, and another onlooker was seriously injured. This was the result of a right front tire puncture, Merz losing control of his National which dashed through the fence and turned over in the crowd near the bleachers stand. Not long after, Keene and a Marmon car met with disaster at the bridge opposite the bleachers, and it was then that Referee S. B. Stevens and President L. R. Speare of the A. A. A. decided that there had been enough for one day. Just before the announcement of this decision, the managers themselves, Messrs. Fisher, Newby, Wheeler, and Allison, had discussed and decided to ask the officials to stop the 300-mile race then in progress. At the time, the Jackson car piloted by Lynch led by over a lap, the Fiat handled by DePalma running second, with Stillman and a Marmon third.

With evident desire to leave the scene, the 25,000 spectators started homeward, some questioning the desirability of sport at the cost of human life, and others morbidly appreciating that they had seen something which they had feared might happen.

To-day there was a meeting of the directors of the speedway, when its future was carefully discussed. Taking all facts into consideration, it was decided that the track could be surrounded with safeguards, for drivers and public, which would permit a continuance of the racing, even if the expenditure totaled a hundred thousand dollars.

In commenting upon the situation, Carl G. Fisher, president of the speedway, said: "We feel there should be no more long events, longer than 100 miles, without new rules. In the first place we feel that drivers should be changed each 100 miles, as well as the tires, and we believe that drivers should be subjected to a physical examination. Loss of life must be prevented at all cost."

Merz, who survived the Saturday casualty, is quoted as not believing in limiting events to 100 miles. Said he:

"I do not think that it is necessary to limit future races to 100 miles. Drivers can go 300 miles all right, but the track should be in good condition. I had a bad experience, but I shall drive again. At the short stretches at either end of the track too much oil had been applied and the track was slippery near the pole. During the early part of the race I kept well in, but one lap I skidded dangerously, and after that I tried it near the outer edge. It was not so slippery there, but rather rough, and severe jolting, I think, caused my tire to explode. Then it was all up with me. Even the long stretches were far too rough; all the drivers complained of it. It was really a road race."

KNOX COMPANY IS APPRECIATIVE

SPRINGFIELD, MASS., Aug. 23—So many telegrams and letters of sympathy have been received by the Knox Automobile Company that its officials have found it necessary to acknowledge receipt of same by issuing a letter, the text of which is given herewith:

Knox Automobile Company,
Springfield, Mass., August 23, 1909.

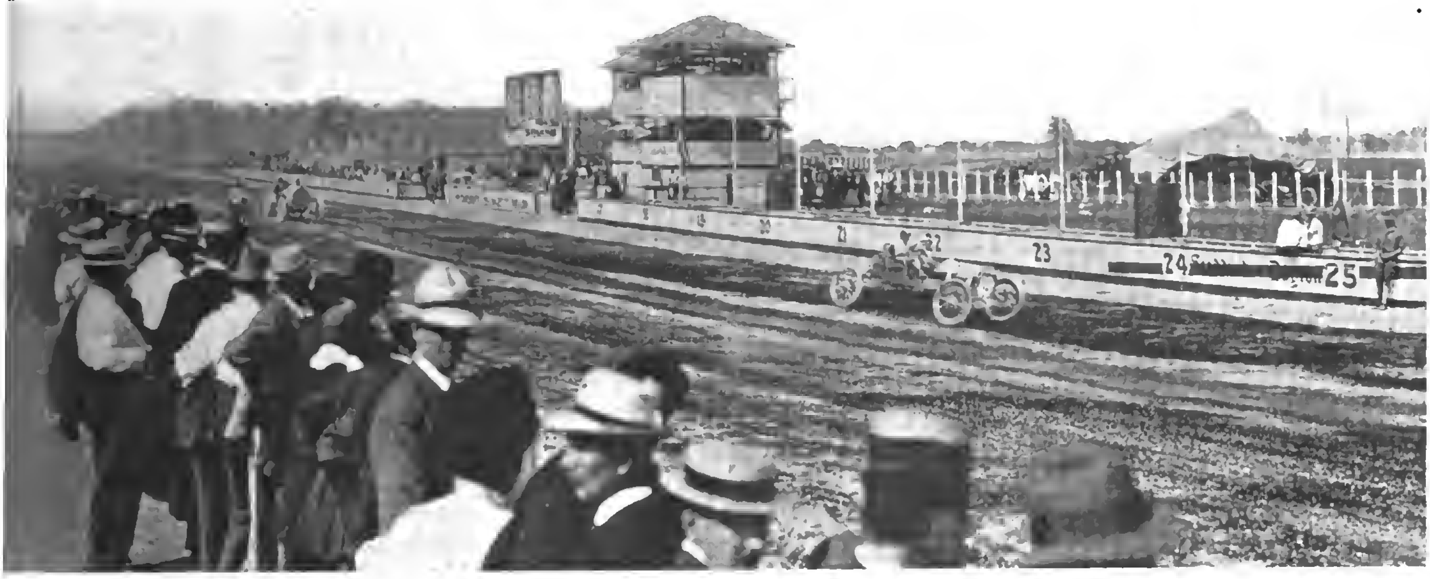
Agents, Customers, and Friends:—

We have received so many expressions of sympathy and inquiries as to the probable cause of the most deplorable accident at Indianapolis, August 19, sacrificing the lives of two of our most deservedly esteemed and trusted employees, we have delayed acknowledgment until we had been privileged with an opportunity to gather as many facts as possible from our own men who were present at the time the accident occurred, and while the exact cause will never be known, we are convinced after a careful consideration of all the particulars obtainable that Mr. Bourque's strength failed him and that he most probably lost consciousness and control of the car before it left the track.

He was not enjoying the best of health and the uncomfortable climate and track conditions demanded more than he had strength to give. He was faithful unto death and to the end enjoyed the support of a faithful helpmate.

All expressions of sympathy are fully appreciated and copies of same have been forwarded to the families of both Mr. Bourque and Mr. Holcomb.

Most respectfully yours,
KNOX AUTOMOBILE COMPANY.



Which Was Won by Stoddard-Daytons, Both First and Second Places Being Captured by These Cars

STORY OF THE FIRST DAY

INDIANAPOLIS, Aug. 19—A Stoddard-Dayton, driven by Schweitzer, achieved the honor of capturing the first race run on the Indianapolis speedway when it finished first this afternoon in a five-mile event for stripped chassis, in the 161-230 cubic inches class, which opened the initial card before a crowd of 15,000 people.

Five races had been carded, and every one produced fast time, although the condition of the track was none too good; in fact, the drivers complained so much about it that, following the accident which resulted in the death of Bourque and Holcombe, Referee Stevens ordered the promoters to improve the circuit before there could be another day of racing. Following this order, Director Moross prepared for a big gang of workmen laboring all night with the steam roller, and also ordered that the track be oiled at least half of its circumference because of the dust clouds raised by the flying wheels.

Prest-O-Lite Trophy Race the Feature

Of course the feature of the day was the 250-mile race for the Prest-O-Lite trophy, the cars being limited to a piston displacement of from 301 to 450 cubic inches, the field including the unfortunate Bourque in the Knox, Kincaid in the National six, and Merz in the National four; Strang, Chevrolet and Burman in Buicks; Miller and Clemens in Stoddard-Daytons, and Ellis in the Jackson.

Chevrolet led at the 10-mile post, and still had it 20 and 30 miles, Burman chasing him. In the fifteenth lap Burman forged to the front, and Chevrolet had to trail. At 50 miles Burman was but 11 seconds ahead of Chevrolet, while Kincaid was two minutes back of the leader, with Bourque, Ellis, Miller, Clemens and Strang following.

Strang was not a factor because of a sensational incident that occurred just as he was finishing his second lap. As he approached the pits it was discovered his car was afire and a hasty stop was made. A fire extinguisher was needed to put out the flames. Then Strang wanted to resume, but an objection was raised, it being claimed that he had received outside assistance in the shape of the fire extinguisher. Strang claimed, though, that as his mechanic had put out the fire there was no outside assistance. Finally, after considerable argument, he was allowed to resume under protest, it being understood the A. A. A. would thresh it out if he did anything.

Burman and Chevrolet had things their own way until the thirty-second lap, when Chevrolet dropped back, and Kincaid, Ellis and Merz passed him. Chevrolet, however, caught Merz. At 90 miles Strang had enough and retired. Passing the first century Burman had Ellis by more than five minutes. At 110 miles Chevrolet had worked back into second place, while Ellis had fallen to fifth place. No change in the order occurred until the fifty-third lap, when Chevrolet again lost his grip on second place and fell to fourth. Bourque began to look dangerous in the fifty-fourth lap, and at 140 miles was second, 28 seconds ahead of Kincaid. Burman at that time was five minutes to the good and going easy.

It was not long after—in the fifty-eighth lap—that the accident occurred which killed the Knox crew, and at the same time Chevrolet retired from the race. At 150 miles Burman was 11 minutes ahead of Kincaid, while Ellis was three minutes back of Merz. Ellis went to second place in the sixty-seventh lap, and at 175 miles he was some five minutes behind the leader, while Clemens had advanced to third. This order was maintained to the end of the eighty-first lap, and then the Jackson deposed the Buick having nearly 14 minutes' lead over Burman at 210 miles, and being 16 minutes 13 seconds to the good at 220 miles. Then came a sensational incident that put the Jackson completely out of the running.

Ellis had just passed the judges' stand, entering his eighty-ninth lap, when his engine stopped and his car coasted to the south pits, whereas, the Jackson box was in the north section. Ellis and his mechanic went to work with feverish energy to resume the race. Victory seemed certain with only 30 miles to go, if only the motor could be started. They cranked and cranked and didn't get a wheeze; then they discovered magneto trouble. But by this time the mechanic had collapsed and was

Where the Cars were Parked

The overflowing Grand Stand

As the Crowd Surged in.

Crossing the Tracks Bridge

carried off the track by Ellis, who was all in himself. The exertion told on him, and he, too, fainted. Thereupon Referee Stevens granted permission for a relief crew to go on, and Tom Lynch undertook the job of piloting. But he also failed to get the engine started, and the dead Jackson stood by the pits while Burman continued on to victory, Clemens being runner-up, while Merz, in the No. 7 National, went into third place when his team mate, Kincaid, failed to get to the tape because of a broken gasoline feed on his last round.

Oldfield Benzed Mile Mark

Despite the roughness of the track, Barney Oldfield, in the Benz, set a mile mark that is likely to stand for some time, doing an exhibition in :43 1-10. Of course these figures have been excelled in road and beach trials, but it is the best ever made on a track in this country.

Wright and Schweitzer in Stoddard-Daytons, De Witt and Ryall in Buicks and Stickney in a Velie were the starters in the opener. Ryall went out the first lap and the Velie was not a contender. The three cars that did fight it out went at a good clip, the time of the winner being 5:13 2-10.

Poor "Billy" Bourque scored his last victory in the five-mile stripped chassis race for cars in the 301-450 class when he showed the way home to Clemens in a Stoddard-Dayton and Merz in the National, his time being 4:45 1-5. In this an attempt was made to use a flying start, but there was so much trouble in doing it this way that Starter Wagner went back to the standing start.

Harroun, of Chicago, driving a Marmon, won the 10-mile free-for-all handicap, in which a good field started. He had a 1:45 handicap.

STORY OF SECOND DAY

INDIANAPOLIS, Aug. 20—The G & J trophy at 100 miles and a 50-mile event furnished the attractions to-day, and six events were run off without accidents of any sort. Proceedings began at noon, and by 1 o'clock there were at least 20,000 spectators. By working all night the management had put the course in better shape than it was on the first day, the surface having been oiled half way around, while the work of the steam rollers was easily noticeable. Zengel in the Chadwick six clipped off 10 miles in 8:23 1-10 as against the 9:12 3-5 made by Oldfield in his Peerless Green Dragon as far back as 1904. Aitken in the National six ran 5 miles in 4:25 as against DePalma's

4:26 in a Fiat at Providence last year. Strang also participated in the feast, clipping the old marks in the G & J trophy race at 100 miles, the century being turned in 1:32:48 5-10.

The fight for the G & J trophy was the feature of the afternoon.' Some of the officials wished to cut the distance to 50 miles. Most of the contestants, however, lodged a strenuous objection. The grind resolved itself into a battle between the special Indiana trophy Buicks and the stock Marmons, the conditions limiting the field to cars of from 231 to 300 cubic inches piston displacement. As it turned out, Strang won and put up a new set of records, the feature of his race being the fact that he ran from start to finish without a stop either for repairs, supplies or to change tires. His time showed he had averaged 2:19 2/10 to the lap, a remarkably consistent performance. The runner-up was De Witt, also in a Buick, who was about 9 minutes back. Two others finished within hailing distance of the winner—Harroun in No. 15 Marmon, in 1:42:37 6/10, and Stillman, also in a Marmon. All three timed got inside the Burman record made at Columbus The Marmons ran consistently all the way through the century and are entitled to considerable credit for their work.

Chadwick Six Takes a Free-for-All

When the field lined up in the ten-mile free-for-all great things were expected, for Barney Oldfield had trotted out the big Benz for its first bit of competition work at Indianapolis. Opposed to him were Zengel in the Chadwick six, Aitken in the National six, Heina in a Lozier, de Palma in Hearne's stock Fiat and Cameron in a Stearns six. Oldfield set a merry clip for the first lap, and had a fine lead at that time. Then he was seen to slow, and in the back stretch the Chadwick went to the front, while the Benz dropped out. It later developed that Barney had met with an accident in the handicap preceding, in which he had driven his "Old Glory" National. He had had to stop in the backstretch, and while cranking the motor the hood came off and struck him on the arm, making a bad cut. This pained Barney, and in the big race he was greatly handicapped. Also a footboard on the Benz had loosened and got under the clutch pedal, so that Oldfield was in sad straits.

After Oldfield had been eliminated there was nothing to it but the Chadwick, which was let out to the limit. The distance of the race was soon covered, and Zenzel came home about

His Concluding Circuit.

an eighth of a mile ahead of Aitken in the National, having covered the ten miles in 8:23 2/10, which amply demonstrated the speed possibilities of the track.

Another speed feature of the afternoon was the mile trial. Yesterday Barney Oldfield, in the Benz, went an exhibition in :43 1/10, and to-day he drove against this mark. The consistency of the Benz was shown by the fact that Barney duplicated his figures of yesterday. Zengel also shot at the mark with the Chadwick, doing :49 3/10. De Palma, driving a stock Fiat and not his Cyclone, got a mark of :48 6/10.

The speed trials opened the afternoon's sport, and following came the 231-300 class race at five miles, in which Strang and Chevrolet, in Buicks, had everything to themselves, third place falling to Stutz in the Marion.

Aitken and National Were Star Pair

Aitken, in the National six, again came into prominence in the ten-mile race for 301-450 class of stripped chassis, in which the runner-up was Chevrolet, in a Buick. De Hymel, in a Stoddard, was third.

Aitken followed this with another victory in the ten-mile for cars that will run for the Wheeler & Schebler trophy to-morrow. In this he trimmed Lytle in an Apperson, having nearly 10 seconds the advantage as the tape was crossed, while Heina, in a Lozier, was third. In the five-mile handicap it was a case of the National being one, two, Aitken in his six getting the decision over Merz, the finish being so close that some disputed the decision of the judges. It probably was one of the most hair-splitting decisions ever turned out at a motor meet, the timers deciding there was only 1/200 ofa second between the two Nationals.

Stoddard-Dayton Ran One-Two

The fifty-mile race shared honors with the century as one of the attractions of the afternoon, and it resolved itself into an easy victory for Stoddard-Dayton, which took both first and second. Ryall and De Witt, in Buicks, and Stickney, in the Velie, were the other starters. The Stoddards were in front at twent miles and stayed there, although De Witt at one time threatened to be a factor, only to fade away.

STORY OF THE THIRD DAY

Indianapolis, Aug. 21—Just when prospects looked brightest for the successful completion of the meet, two accidents brought racing to a sudden end this afternoon and prevented a winner being evolved in the Wheeler & Schebler cup race at 300 miles. Merz, in the National, ran off the bank near the bleachers, and the accident resulted in the killing of two spectators and the death of Kellum, the accompanying mechanic. Before the horror-stricken crowd had time to recover from the effects of this, Keene in a Marmon skidded and hit a pole. His mechanic suffered a fractured skull, and thereupon the officials decided to stop the race, it being evident that the drivers were greatly fatigued and that if the event went the full distance there might be more accidents. At the time the race was stopped, 235 miles, the Jackson was in the lead and seemed to have a good hold on first place. But Referee Stevens would not give it the race, and in the evening, after a consultation with his fellow officials, he issued the following statement:

> Owing to the physical condition of the contestants who had been subjected to the strain of a three-day race meet under trying climatic conditions, I deemed it to the best interests of the entrants and spectators to abandon the race, therefore I rule no race and no awards. In conclusion, however, I recommend to the management of the Indianapolis Motor Speedway and to the donors of the trophy that suitably engraved certificates of performance be presented all contestants in active participation in this event at the time of its abandonment, and that they be signed by the management of the speedway, the donors, and the referee.

At the time the race was stopped Lynch in the Jackson had completed 235 miles, his time for that distance being 4:13:51 4-10. De Palma in the Fiat, was second, and Stillman in the plucky

little Marmon third. Harroun in a Marmon, and De Hymel in a Stoddard, were also running—five out of eighteen starters.

The race itself was replete with sensational incidents. At the very start Johnny Aitken in the National six jumped out and beat it. He soon had a good lead over his fellows, with Lytle in the Apperson being closest. The half-century showed Aitken more than three minutes to the good.

Lytle Figured in the First Accident

The first scare of the afternoon came in the twenty-fourth lap when Lytle escaped a serious accident by his skillful driving. He had just passed the pits when a steering arm broke and left Lytle almost helpless. The car made a wild dive for the fence, but Lytle with control only over one front wheel managed to pull it away and run up the bank. He had slowed by this time and from the top of the bank he slowly drifted to the pole, just escaping being hit by one of the cars following him. When the bottom was reached the Apperson struck a pile of dirt, the mechanic was thrown clear and Lytle stepped out unhurt. The car had been moving so slowly that no damage was done. Lytle went to work and repaired the damage and resumed when the race had reached 175 miles. He was so far behind, though, that he hadn't a chance in the world of doing anything.

Following the Apperson incident Aitken continued to burn it

and had turned the century with a new record to his credit. The National was running so well that even at this early point it seemed as if Aitken's name would be the first engraved on the $10,000 trophy. But in the very next lap a cracked cylinder developed and Aitken had to quit, leaving an opening for Burman to become the leader. The Buick star went to the front and showed first at 125 miles, but soon after he went down and out, leaving the field to Lynch in the Jackson, De Palma in the Fiat, and Stillman in the Marmon.

How Kellum Ran to His Death

Merz in the National four still was in the running and for a few laps after his team mate had quit he had been in front. Trouble overtook him though when he had to stop in the back stretch. He stopped his engine and when he tried to start it again he discovered his storage battery was dead. He and his mechanic, Lyne, were too tired to start on the magneto and so Lyne was dispatched across the infield for a new battery. It was a long run, nearly a mile, and Lyne arrived at the pit in an exhausted condition, collapsing when he reached there, whereupon Kellum was delegated to take his place. Kellum had been mechanic for Aitken until the six had been forced out, but he cheerfully picked up the battery and ran across the field with it, going to his death, as it afterward turned out.

Merz started to recover lost ground and was making good progress. He had passed the double century mark and had swung into the first turn. He had got half way around the bend and was nearing the bleachers when a front right tire punctured. The National shot up the bank and over the edge just where the bridge abutment is located. It posed for a second on the brink, then toppled over, striking a fence on which sat a row of spectators. It was a danger point and there was a huge sign there warning people to keep away, and it is stated that the police had driven them off several times. The crash of the car killed two outright, Ora Joliffe of Trafalgar, Ind., and an unknown man. Kellum was so badly injured that he died soon after. Merz, though, had a lucky escape. He was caught under the car when it turned over but was not hurt, retaining presence of mind enough to turn off the power before he crawled out.

Only three other races were run and there was an attack on the kilometer record which resulted in Oldfield in the Benz going the 5-8 of a mile in :26 2-10. Christie did :28 7-10, and Zengel in the Chadwick :29 9-10.

Oldfield Won the Remy Brassard

A remarkably fast race was run for the Remy brassard, which has been put up by the magneto manufacturer and which carries with it a salary of $75 a week as long as it is held. Oldfield went after the money and got it, leaving behind him a trail of new records. He finished the quarter-century in 21:21 7-10, the Fiat being second in 22:44 4-10, and the Chadwick third in 23:07 8-10.

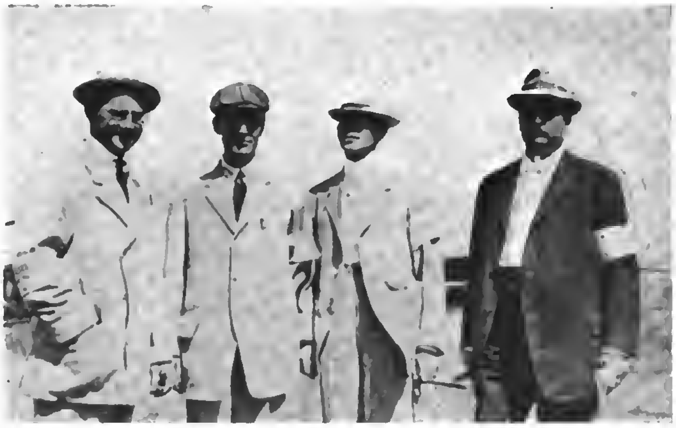
HEARD AND HAPPENED AT INDIANAPOLIS

President L. R. Speare, of the American Automobile Association tried his best to have the three hundred mile race at Indianapolis cut down to 100 miles, and then tried to compromise on two hundred. Mr. Speare watched the race with dread, and finally, after the second accident, immediately counseled stopping it. Asked whether the accidents would result in any action on the part of the A. A. A., he said: "The accidents were

In Front of the Pits There Was Action

Merz, the National Driver, Winner and Loser



Speedway Four: Fisher, Allison, Newby, Wheeler

Start of G & J Trophy Race Which Strang Won the result of conditions which may be corrected, and will be. I see no reason now for raising any bars against future contests.

As in the days of cycle racing, the public has grown to believe in the man as much as in the machine, and the cheers are for the men with whom, through past performances, they are acquainted. In the grand stands at events will be heard: "What do you know about that. Barney has just let that fellow go by him. Why don't he hurry up. Barney is not a quitter." These and similar remarks show plainly the feeling of the people and add zest to the sport which was not there in the early days when the feeling was general that it was the machine and not the man that was doing the racing.

"Go out, boys, and do your best to win, but without taking chances," said Mr. Wright of Springfield when Dennison and Bourque left for Indianapolis. "Remember," continued Mr. Wright, "you boys are very dear to us here, and we want no wins at the sacrifice of safety. We merely want you to drive within the safety limit, but finish the contest." Dennison promised, as did Bourque.

"No married men need apply," is the verdict of one maker of automobiles who oftentimes dabs in speed contests. This maker issued the edict before sending his team to Indianapolis, and by a chance a married did get on the team. The man was killed, but not at the track, and the wife, of course, blamed it all to the maker, although the husband had always claimed that he was not married and steadily carried through the deception to gain a place on the racing cars.

BOURQUE WAS TO HAVE BEEN MARRIED

SPRINGFIELD, MASS., Aug. 22—Wilfred Bourque, who was killed while competing in the automobile races at Indianapolis last Thursday, was to have been married September 14 to Miss Alexina Boivin, of West Springfield, and two of their friends, Prosper Dufresne and Miss Eugenie Parent, had planned to make the wedding a double ceremony. Bourque's fiancée was opposed to his racing, and he had promised her that after the Vanderbilt cup event this fall he would not race another car.

Over 300 employees of the Knox Automobile Company met the bodies of Bourque and Harry Holcomb on their arrival from the West and escorted them to their homes. Fully 5,000 persons were at the railroad station when the train arrived.

The funeral of Mr. Holcomb was held this afternoon in the Methodist Church in Granville, the Rev. Philip L. Frick officiating. The funeral of Mr. Bourque will be held to-morrow morning at St. Louis' Church in West Springfield.

STODDARD-DAYTON OUT OF RACING

DAYTON, O., Aug. 24—Charles G. Stoddard, vice-president of the Dayton Motor Car Company, announced to-day that the local company would never again enter in a racing event. The Dayton concern conducted a large excursion to the recent meet at Indianapolis, when 1,800 residents of this city saw the races and accidents which marred the sport.

Mr. Stoddard says automobile races not only cause men to risk their lives unnecessarily, but that the motor car business is damaged every time a man is hurt.

MEETING OF M. C. A. RULES COMMITTEE

INDIANAPOLIS, Aug. 21—The general rules committee of the Manufacturers' Contest Association has held several sessions during the speedway races, and definite plans for another year have been decided upon, though no announcement will be made for the present. The M. C. A., through its advisory committee to the contest board of the American Automobile Association, is going to ask for several changes in the present agreement involving the two organizations. President Benjamin Briscoe and Chairman H. E. Coffin of the rules committee, presided at the meetings, which were well attended.

POSSIBILITY OF 1909 VANDERBILT RACE

H. E. Coffin, chairman of the general rules committee of the M. C. A., has notified the prominent makers of the country that a race for the Vanderbilt cup will be held if a sufficient number of entries to insure the success of the event are pledged on or before September 1. The mails and telegraph are being used in a thorough canvass of the situation. If the makers guarantee the required number of entries the race will be conducted by a new association, formed pursuant to the A. A. A.-A. C. A. peace agreement, which will assume the custody of both the Vanderbilt and the Grand Prize cups.

The actual incorporation of this holding body will take place when the Vanderbilt race of this year is assured. In its membership are automobilists of national reputation.

By a change in the deed of gift the Vanderbilt trophy will become one for stock-car competition, under rules recommended by the Manufacturers' Contest Association, as follows:

1. The Vanderbilt cup race shall be open to cars of classes 1 and 2 of division B, under the classifications of the A.A.A. racing rules for 1909.

2. A cup will be offered for class 3 and another for class 4 under the same division, to be raced for at the same time and on the same course, but at shorter distances.

These classes call for competition under piston displacement, and were recommended as providing a possible race for existing stock cars, as the time was realized to be too short for the building of any new cars for this special event.

The race will be held over the portion of the parkway used in 1908, with probably the same Nassau County roads. A request has been made, however, that the course be shortened, and engineers looking into the matter have found this to be possible. If the short course is finally decided upon, it will probably be about four miles less than that of 1908.

All preliminary details regarding the race have been quietly perfected, and now the situation is up to the makers. If held, the race will take place the latter part of October.

METROPOLIS MAY HAVE A MOTORDROME

NEW YORK, Aug. 24—New York may have an automobile track within a few minutes of the great business district. The proposed location of the course is on the meadows just outside of Jersey City, where the McAdoo tunnels will reach the spot. For some time these meadows have been filled, and a vast area is now ready for factory sites or anything desired. The immense attendance at automobile events all over the country attracted the attention of the McAdoo interests and P. S. Parish and W. M. Jacobus, accompanied by A. A. Alexanded, made a flying trip to Indianapolis. The great crowds and the evident interest, created a most favorable impression, and the trio made a thorough inspection of the track and grounds before leaving. It is said that the venture will tie up two and one-half million dollars.

TEN ENTRIES FOR NEXT BRIGHTON "24"

NEW YORK, Aug. 24—Entries for the 24-hour race, which will be held on Friday and Saturday, on the Brighton Beach track, closed to-day with ten nominees. Eight of these are of American production, one is from Italy and one is from France. The track has been much improved since the last contest and records are expected to be broken. Harlan W. Whipple has been chosen referee. The entrants are as follows:

No.	Car	Drivers
1	Renault	Basle and Raffalovitch
2	Palmer and Singer	Howard and Lescault
3	Acme	Patschke and Van Tine
4	Acme	Dearborn, other not announced
5	Lozier	Cobe and Heina
6	Stearns	Mulford and Laurent
7	Houpt	Robertson and Poole
8	Allen Kingston	Hughes and Lawwell
9	Fiat	DePalma and Parker
10	Rainier	Disbrow and Lund

The entries for the six-hour race for smaller cars, and those for the short distance events, close to-morrow.

Paulham in Voisin Biplane

Arrival of Curtiss Aeroplane in France

Tissandier in the Wright Biplane

CURTISS OPENS RHEIMS TOURNAMENT WITH RECORD

RHEIMS, Aug. 23—Glenn H. Curtiss, the lone American representative at the International Aviation Week, at present holds the record of the course, and is the favorite for the Gordon Bennett race next Saturday. He covered the 6 1-5 miles of the circuit in 8:35 3-5, at the rate of 43.3 miles an hour.

Practice for the meet began in earnest [redacted]sday, and that day saw a most spectacular exhibit of aeronautic skill. For the first time in history three aeroplanes were in the air at the same time. They were Dumanest's Antoinette monoplane, Tissandier's Wright biplane and Curtiss' machine. All were flying rapidly about the field, when suddenly Curtiss saw Dumanest about to cross his course at right angles and on the same level. A collision seemed imminent, but Curtiss easily guided his machine upward and soared over the Frenchman.

A driving rainstorm swept over the field Saturday, and on Sunday, the first day of the meet, the sky remained cloudy and the wind erratic until shortly before dark. Then there was a great rush to the sheds. Latham was first away, and others quickly followed; soon the spectators beheld six aeroplanes in flight at the same time. Latham completed two rounds, Lambert four, and Lefebvre and Tissandier, the other Wright pilots, three each. The work of Lefebvre, who is self-taught, is one of the sensations of the meet; he made the fastest lap of the day, in 8:55 4-5. Curtiss did not appear, as he has but the one machine and cannot afford to risk an accident.

In contrast to yesterday, blue skies, sunshine and only a trace of wind made ideal conditions for the aviators to-day. Most of the day was taken up by flights to qualify for the Prix de la Champagne, which has an aggregate of prize money of $20,000. In these trials Lefebvre, Bleriot, Sommer, Latham, Tissandier, Farman, Lambert, Delagrange, Gobron, Bunau-Varilla, Cockburn and Sanchis-Pesa made flights of from 200 meters to 25 kilometers. Paulham on his Voisin biplane was the only aviator to make a real distance trial. He made two beautiful flights at a very high altitude of 49.5 and 56 kilometers, respectively. Curtiss was the last to appear. The time limit for the trials had almost expired, and the Americans had abandoned hope of seeing him take the field when his machine appeared. After a preliminary run along the ground of 100 yards it rose easily and shot by the stands at a height of sixty feet. He made the last turn under the impression that the finish line was closer, and descended so close to the earth that many thought he touched. However, he discovered his mistake in time, rose quickly and crossed the line. Soon after it was announced that he had established the record of 8:35 3-5 for the 10-kilometer circuit.

David Lloyd-George, the British Chancellor of the Exchequer, is much interested in the Curtiss machine. Although Hart O. Berg, the manager of the Wright company, was in constant attendance on him, the Curtiss shed was the only one which the Chancellor favored with a second visit.

Americans here generally regret the news that the Wrights are suing Curtiss for infringement on their patents. Curtiss himself expressed much surprise. Cortlandt Field Bishop, the president of the Herring-Curtiss company, maintains that the Wright claim of a basic patent is unfounded, and that Curtiss does not infringe on the warping wing principle, which is the distinctive Wright feature.

The judges have selected MM. Bleriot, Lefebvre and Latham as the French team for the Gordon Bennett race.

The aviators at present on the field include MM. Paulham, Fournier, Ferber, Gobron, Rougier and Bunau-Varilla, flying Voisin biplanes; MM. Lefebvre, Tissandier, Lambert, Gasnier and Schreck, with Wright biplanes; MM. Latham, Dumanest and Burgeat, with Antoinette monoplanes; MM. Sommer and Farman and Mr. Cockburn, with Farman biplanes; MM. Bleriot and Delagrange, with Bleriot monoplanes; MM. Pelterie and Geoffroy, with R. E. P. monoplanes; MM. Sanchis-Pesa and Fernandez of the Spanish team, and M. Santos-Dumont and Mr. Curtiss on machines of their own construction.

Bleriot Breaks Curtiss' Record

RHEIMS, Aug. 24—Louis Bleriot to-day broke Curtiss' record for the 10-kilometer course by covering the distance in 8:04 2-5, which is at the rate of about 47 miles an hour. The most sensational performance of the day, however, was a 30-kilometer flight by Paulham, part of the time at an elevation of 500 feet. A 20-mile breeze was blowing, and the aeroplane rocked dangerously. As he swept down from this great height at the finish many of the spectators thought he was falling, and cries of horror went up. But he righted himself easily only twenty feet from the ground, and crossed the line on an even keel. The flight was made for the especial benefit of President Fallieres, who came from Paris to witness the meet. Latham also made three rounds at good speed. Lefebvre, the Wright pilot, was fined $4 for his recklessness on Sunday; but the management added its congratulations.

Squad of the Seventh Regiment, New York, Awaiting the Enemy

How The Auto Played Its Part

IT is seldom that the tourist has such splendid opportunities for seeing new and interesting scenes as were presented last week in Plymouth County, Mass. Not since the days of King Philip and his Narragansett warriors has there been so much excitement in the region. The Red army, consisting of detachments of the National Guard of New York, New Jersey, Connecticut and the District of Columbia, had effected a landing at New Bedford, with the announced purpose of marching northward and capturing Boston. The National Guard of Massachusetts, designated the Blue army, had been called into the field to check the advance o fthe invaders. The terrain over which the contending forces were scattered was not less than 30 miles square. Obviously, the only possible way of covering this wide stretch of country and of seeing what was happening was by automobile. This opinion, which had brought me to the scene in my White steamer in the capacity of interested observer, was also held in high official circles, for when I made an inspection of the different camps, I found that there were no less than six automobiles of the same make as my own in official service. Most prominent of these users of the motor car was General Leonard Wood, Commander of the Department of the East, who acted as chief umpire and had supervision over the maneuvers. At the conclusion, General Wood said that he had traveled an average of 150 miles a day, and that it was only through the use of the automobile that he had been able to keep fully in touch with what was going on. This is surely a significant statement coming from the officer who is the ranking general of the United States Army. I remember that at the military maneuvers in Pennsylvania, three years ago, General Fred D. Grant declined to ride in an automobile on the ground that it was not dignified for one of his position to travel about the camp except on horseback.

No less than five White steamers formed a part of the military equipment of the Blue army. Three of these cars were attached to the head-

In Mimic Warfare About Boston

By Pathfinder

quarters of Brigadier-General Pew, Commander of the Blue army, and were used by him and his staff almost continuously in carrying orders to his widely scattered forces. There is no doubt that, had it not been for these cars, General Pew would have made a less effective defence of Boston than he did, for his troops were spread out in a thin line from the seacoast to the Taunton River. During the first two or three days all of the camps were in touch with General Pew's headquarters by means of telephone wires rigged by the Signal Corps, but in the later days the Blue army did not have any time for such operations, and General Pew relied entirely upon his White steamers to keep in touch with his scattered forces, for, be it remembered, the rules of the game created the fiction that all ordinary means of transportation and communication were destroyed and the armies were thrown entirely upon their own resources.

Quite as much appreciated by the Blue army was the White steamer ambulance, attached to the division headquarters, and there was no "make-believe" about the work of this car. Although no bullets were flying about to bring injuries to the contending armies, the hospital corps on each side was kept busy, treating cases of heat prostration and the ordinary ailments to which flesh is heir. In the Blue army of 7,000 men, such cases manifested themselves very frequently, and it is not surprising that it was found necessary to have two chauffeurs for the automobile ambulance, as it was in practically constant service. The driving of this ambulance was by no means confined to the public roads. On more than one occasion I saw it making its way through the fields to reach the side of some citizen-soldier who had collapsed from sheer exhaustion while maneuvering with his company.

The above does not completely catalog the extent to which steamers were used by the Blue army. Quartermaster-Sergeant Hathaway drove his steamer, using kerosene as fuel, and, as he was in charge of getting supplies to the division headquarters, it can be readily imagined how useful this car proved itself to be.

Packard Truck Successfully Employed in Massachusetts War Maneuvers

One point which was especially made manifest was the feasibility with which a regiment on a forced march could be transported with the aid of a number of motor trucks. A car like the Packard, with a carrying capacity of 40 men with guns and haversacks, could cover in two hours the ground that it would take infantry a whole day to get over. If, in such cases, 30 trucks were available, a whole regiment of infantry and its baggage could be transported between 50 and 75 miles in a single day.

Probably 50 or 60 officers of the regular army were present at the maneuvers, serving in the capacity of umpires, observers, or as advisers to the respective armies, and the work of these automobiles was thus brought forcibly to the attention of some of the most active officers on the roster of the War Department.

Never have I passed a more interesting week in an automobile than when observing the movements of the two armies. By the rules of the game, the fighting and forward movements of the contesting forces were restricted to the hours between 5 o'clock in the morning and 1 o'clock in the afternoon. We chose as our headquarters for the week the quaint old King Philip Tavern, located about 20 miles north of New Bedford, on the shores of the Assawompsett Pond. This hotel was also the headquarters of a number of the regular army officers serving as observers, and the atmosphere pervading the place was decidedly military. Each morning we arose at daybreak and took on board five or six army officers, and were at the scene of action by 5 o'clock. We moved unmolested through both the Blue and the Red lines, and were therefore able to see all the fine points of the game. Occasionally, we would find the roads so blocked with troops and army wagons that advance was impossible, in which case we would detour and get on the nearest parallel road and in this way reach the head of the column. In making some of these detours I took my car through some swampy, sandy roads which would do credit to Southern Georgia. I should say here that in traversing the highways and byways of what was to me an entirely new country, and in keeping posted on the movements of the two armies, I depended entirely upon a set of Pilot road maps of New England and found them accurate to the last degree and absolutely invaluable.

Major-General Bliss, the head of the War College at Washington, was in command of the Red army, and Brigadier-General Pew, of the Massachusetts Militia, led the Blue army of defence. Perhaps it will not be out of place for me to give a brief summary of the maneuvers, because no one, unless riding in an automobile, could gain any comprehensive idea of what was going on. The first position of the Blue army was in an east-and-west line extending from Taunton to the coast. On Monday, General Bliss made such a disposition of his army as to indicate that he intended to attack the right flank of the Blues. Immediately, General Pew started to concentrate his troops on his right. This move on General Bliss' part, however was only a feint, and on Tuesday he sudden shifted his troops and, by forced marches moved against the weakened left flank of the Blue army, which, at the close of the day, he had effectually penetrated. It was a case of the entire Red army massed against a single regiment of the Blues, and there was nothing for the umpires to do but to declare the regiment of Blues annihilated.

Thereafter the advantage was always with the invaders. Their army was concentrated, while the Blue army was spread out. There was incessant fighting at every crossroad, but the northward march of the Reds never halted. A battalion or regiment of Reds would deploy into each crossroad and would engage the attention of whatever Blue troops were in the vicinity, while the main Red army continued their march. When the main body had passed the crossroad, the skirmishers would be drawn in and would continue for the time being as the rearguard of the Red army.

Riding now with the advance guard of the Red army, now in their rear with the skirmishers, and then again visiting the detachments of the Blues, we had a comprehensive view of the movements of both sides, just as though we were seated comfortably in a grand stand watching a football game. Indeed, the analogy between the war game, as we saw it at close range, and a football contest, is a very close one. The Reds, we will say, had the ball and the Blues were spread out protecting equally all parts of their line. The action begins and the Reds mass themselves as if to go around the right end of the Blues. Immediately, the Blue defence rush to that side, when the Reds, changing the direction of their attack, actually get the ball around the left end of the Blues. Thereafter, it is a run for the goal. The Blues, recovering from their surprise, try to head off the runner, who corresponds with the main advance of the invaders; but all they can do is to come up on his flank, where they are held in check by the "interference," corresponding with the skirmishers, which the Red army sent into every crossroad. But before the goal is reached, time is called, just as it was in the maneuvers. The Red players have almost a clear path to the goal, although they are much harassed on the side and from the rear, just as General Bliss had an open road to Boston but found his left flank under constantly increasing attack. The expiration of the allotted time keeps the Red players from scoring, just as the Red army could not accomplish their announced purpose of camping on Boston Common. To the Blue players belong the credit of having fought so valiantly as to seriously delay operations, just as the Blue army in Massachusetts, theoretically, saved Boston from capture by their gallant recovery from their initial mistake in maneuvering.

As in all warfare since time began, the cavalry were of much greater effectiveness than the infantry, simply because they could cover a greater amount of country in a given time, than the unmounted men. Could not a motor corps be even more useful than cavalry for the same reason, namely, because of the greater territory they could cover? There was no time during the maneuvers when a motor corps of, say, 300 men, carried in 50 cars, could not have caused the utmost confusion in the ranks of either side by capturing the supply trains, cutting communications and defeating detachments sent out on scouting duty. This is not simply a layman's opinion, but is concurred in by all the officers of the regular army with whom I discussed the proposition.

Does it not seem that, with the Army experimenting with aeroplanes, and the Navy adding submarines as part of its regular equipment, too little has been done in official circles toward utilizing the motor car for purposes of offence and defence? At any rate, the problem is looked upon with too much equanimity, considering foreign activity in this line.

Practices in Water-Cooling

Chapter III

LIMITING the escape of heat from the cylinder to the water in the jacket limits the requirement of surface of the radiator without in any way interfering with the efficiency of performance of the motor. Having done all possible to limit the work which the radiator must do, the remaining problem is to provide a radiator of adequate ability, which is a matter of radiating surface, in amount depending upon the disposition of the same.

In certain classes of work square-tube radiators are used, and the tubes are about 5-16 x 5-16 inches square, measuring outside, with the walls about 0.008 inches thick. These tubes are made of copper, and the length of the tubes, which measures the depth of the radiator, ranges between three and six inches, depending somewhat upon the power of the motor, which variable is dictated by the nearly constant front area of the cars, without respect to power of the motor used in them.

Ability of Gill-Tube Radiators—When the tubes are provided with gills, assuming that the gills are in actual contact with the metal of the tubes, the results are very good, and in a general way the efficiency will be on a basis as follows:

CONDITIONS GOVERNING TUBE RADIATORS

Number of Tubes Deep	Square Inches of Surface per H.P.
1	34
2	18
3	12
4	9

The above statement depends for its accuracy upon the proportion of the gills, remembering that the radial outside diameter of the gills, if considerable, will reduce the area of the effective surface, on the ground that the internal conduction in the metal of the gills is directly proportional to the difference in temperature and inversely proportional to the radial thickness. In counting all the surface of gills account must be taken of lack of effectiveness of the same relatively to direct radiating surface, hence effective surface must be determined.

In the circulation of water, if cooling is to be effective when the motor is running slow on a retarded spark, which is the worst condition to be encountered, the amount of water which will have to be circulated will be on an approximate basis as follows:

AMOUNT OF WATER REQUIRED TO BE CIRCULATED

Diameter of Cylinder in Inches	Pounds of Water per H.P. per Minute
4	1.10
4.5	1.30
5	1.60
6	1.80

Increasing the rate of circulation of water ceases to do a proportional amount of cooling after a certain speed is reached, and in a general way the following will hold:

VELOCITY OF WATER CIRCULATING IN RADIATOR TUBES

Velocity of Water in Feet per Minute	B. T. U. per Square Foot of Radiator Surface
5	41
10	46.9
15	49
20	50.1
25	50.92
30	51.3
35	51.89
30	52.1

The above is for efficient radiator tubes, and in a general way it may be said that other radiating surfaces are a little less than one-third of the value of the tubes; that is to say, the shell of the radiator and the piping, etc., may be counted upon as being of less than one-third of the efficiency of the tubes, of the right design, properly placed.

Considering Location of Radiators—Almost without exception radiators are located in the front of cars and so set that air currents pass almost unobstructed through the passageways. The square tubes are banked so closely that the water, which is on the exterior, is as a very thin sheet, while the air fills the space within the tubes, passing through, approximately at the rate the car travels ahead, and when the car is not traveling, if the motor is running, it is necessary to induce artificial circulation of the air, at a rate sufficient to answer the same purpose. In a general way it is considered that the speed of the

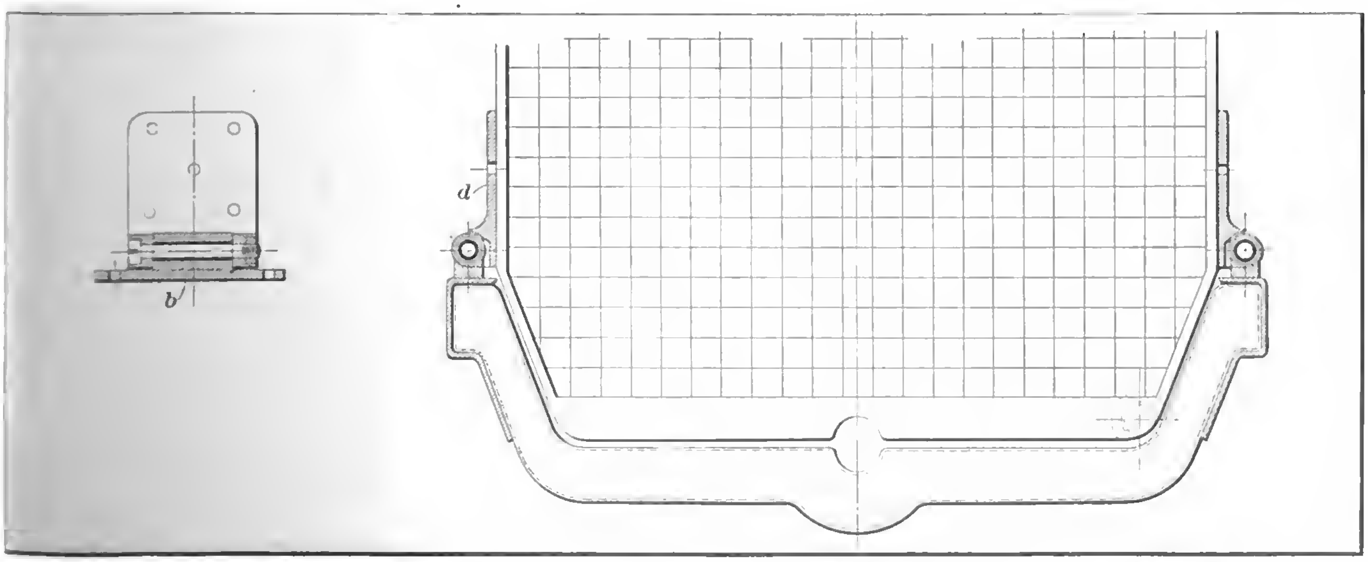

Fig. 8—A method of securing radiators, using the principle which prevents straining by avoiding rigid fastenings

air through the radiator tubes should be about 20 miles per hour (about 30 feet per second) for the best results and fans are frequently designed to displace enough air to render the velocity of the same about 30 feet per second when the motor is making about 400 revolutions per minute.

With square tubes of the size and character as above referred to it takes about 225 square inches of surface, over which the air must brush at the rate of 30 feet per second to keep the water from reaching the boiling point, considering each horsepower actually delivered by the motor. True, there are numerous conditions which will tend to reduce this requirement. The above estimate is for a radiator in which the square tubes are 5 inches long, and as the tubes are shortened within certain limits, the area of surface over which the air traverses may be reduced, but the front area will have to be increased accordingly.

To some extent the amount of radiator surface will change with the size of the motor, it being the case that the escape of heat to the radiator through the water is in direct proportion to the internal surface of the cylinders, measuring all the surface that is brushed by the heated products of combustion, assuming that water is in contact with the external surface. This statement is on the assumption that the temperature of the flame is substantially constant in the several motors and that the temperature of the water in the jacket will be the same in each case, thus indicating a constant difference in temperature; should there be a difference in these particulars, an adjustment will have to be made to suit. Differences in compression, or if the fuel differs from gasoline, will demand special treatment.

If round or other shapes of tubes are used instead of square the surface should be the same, or nearly so, and the ratio of water (thickness of the sheet) to air section in the tubes should be on the same basis. This is assuming the tubes are in the horizontal plane, as given in front elevation in Fig. 8, whereas, if the tubes are vertical, the effective area will have to be determined, which effective area may not be equal to the exposed surface of the tubes, since if the air strikes against one face of a tube it will glide around the same and is prone to glide away without contacting with the surface opposite the contact surface. Radiators made up of flattened (thin) sheets, presenting but a thin edge at the contact, at the front, and with both sides for a considerable distance (perhaps 4 inches) brushed by the

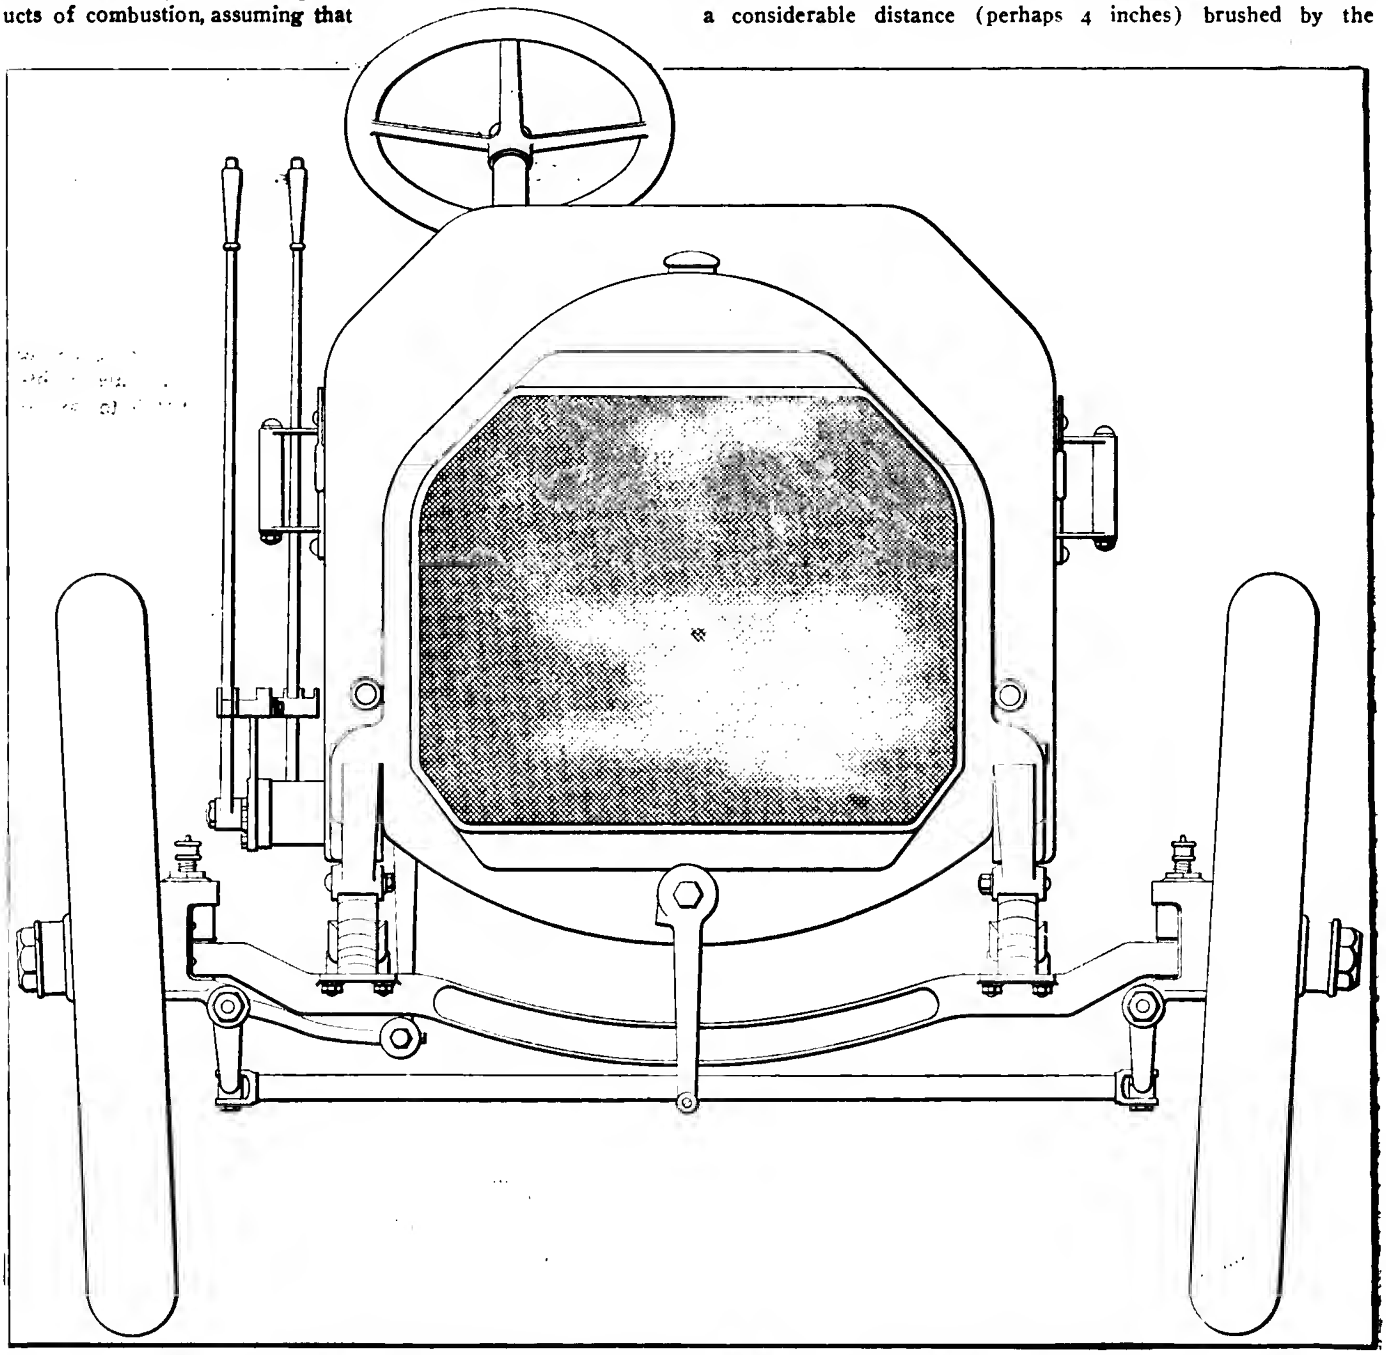

Fig. 9—Front view of a Moore car, showing how the radiator influences the appearance of the car

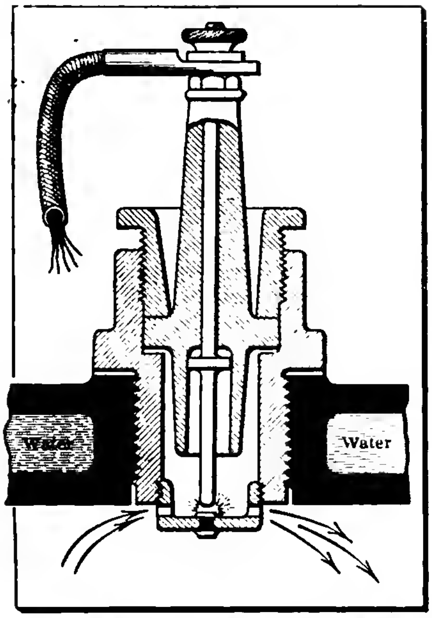

Fig. 10—Section of a cylinder showing water jacketing around the spark plug

current of air are probably quite as efficient as tubes in the horizontal plane, with air passing through the tubes, as in the honeycomb types of radiators.

Centrifugal Types of Water Pumps Are Mostly Used — In this type of pump the height of lift of water will depend upon the tangental force, and not upon the tightness against the housing of the vanes of the wheel. On this account centrifugal pumps can be made of aluminum for the housing, which is light and strong enough to withstand the pressure, but the wheel should be made of a good grade of phosphor bronze. In these pumps, as usually designed, the suction takes place at one side, around the axis of rotation, as shown in Fig. 15, which is a section of a conventional form of centrifugal pump as used in this service, and the suction pipe is made of liberal area, very short, and free from air leaks. The vanes are not fashioned for the highest efficiency, but they are easy to turn up, on centers, in a lathe, which is a matter to be considered.

In this type of pump the quantity of water discharged will be dictated by the area of the discharge pipe, and the head against which the pump will work, within certain limits, depends upon the peripheral velocity. Under the circumstances it is necessary to gear the pump as high as the crankshaft speed as a minimum, and in general practice it is frequently found that the pump shaft rotates considerably higher than the speed of the crankshaft. Considering the lowest speed at which it may be desired to run a motor at which the velocity of the centrifugal pump should be that in view of the diameter of the pump-wheel, which will afford a peripheral velocity of 500 feet per minute as a minimum value.

If the pump is relatively inefficient and speeded to a sufficiently high point to assure that an adequate supply of water will circulate at the lowest speed at which it is desired to run the motor, the troubles of excess water at the higher speeds will be aborted to some extent at any rate. It must be remembered that the head, against which the pump will lift, is as the square of the velocity, and since the most water is really wanted when a motor is running slow, under a retarded spark, centrifugal types of pumps have the fault of lifting the maximum just when it is least in demand.

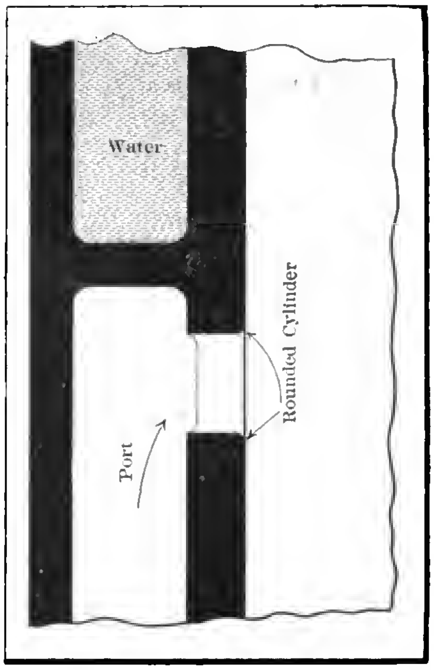

Fig. 12—Defective water jacket around port in a two-cycle motor

In centrifugal pumps there may be any number of arms within certain limits, as, for illustration, six vanes are sometimes used, but as these pumps are used in automobile work it is the general practice to have three vanes, and the curving is away from the direction of rotation, an amount which is not necessarily of great importance in view of the desire for relative inefficiency at the higher speeds.

With gear pumps the situation is quite different, since the capacity is decreasing as the speed increases, and the amount of the decrease in capacity depends upon leakage, which increases somewhat as the speed. This class of pumps should not run faster than the camshaft, which in a four-cycle motor is half the crankshaft speed. If the pumps are run at a higher speed they will give out much sooner, and noise is difficult to avoid. The limit of speed from the noise point of view is 1,000 feet per minute, counting at pitch line of gears just as in gearwork in general.

Reciprocating (plunger) pumps do not seem to have a place in this class of work, due in a large measure to limited capacity, or, better yet, to the space they would occupy, which is at a premium under the bonnet in view of the room taken up by the motors and accessories. There is a series of paddle pumps from which to choose and when they are properly applied, which is a matter of limiting the speed and using a pump large enough for the work, considering limited speed, they seem to do very good work just so long as they remain tight.

Radiator Fixes the Appearance of a Car—There is no one unit in the makeup of an automobile which has such a large

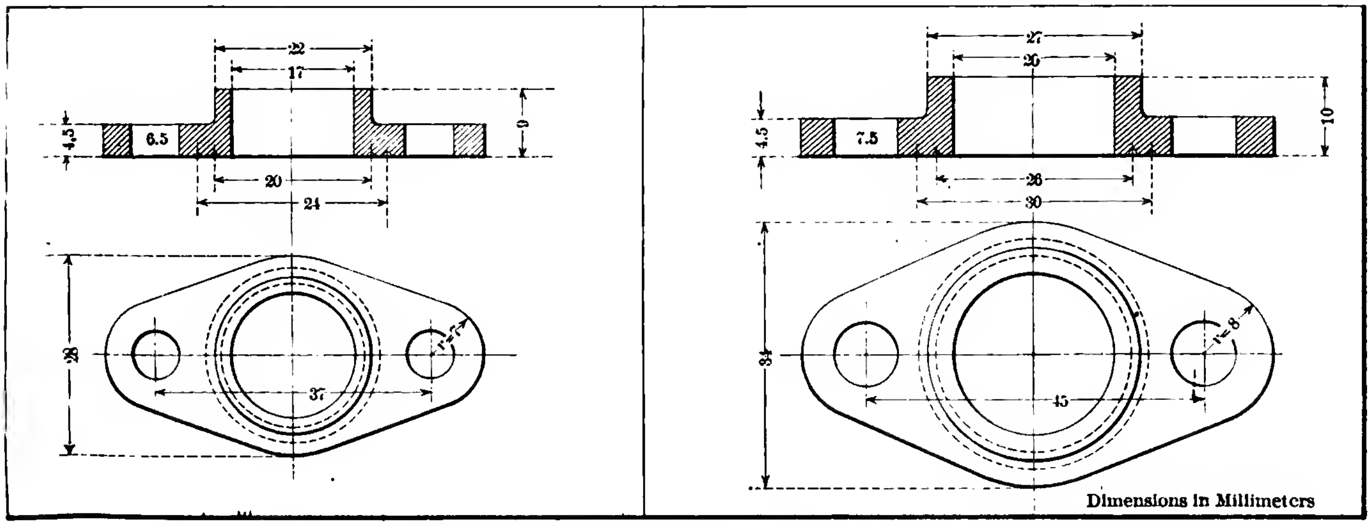

Fig. 11—Design of drop forged steel flanges for use with water piping avoiding heavy and frail castings

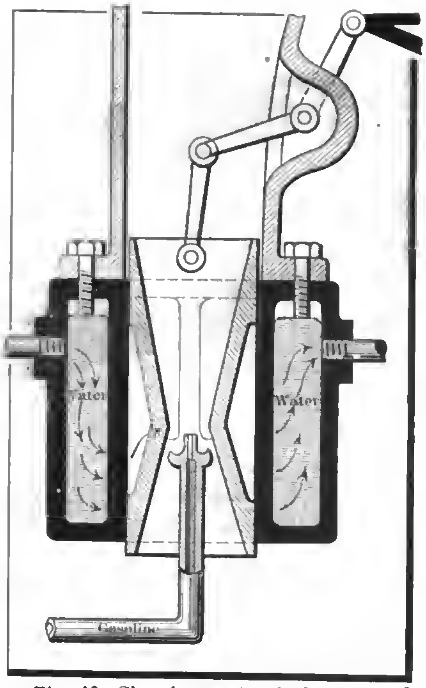

Fig. 13—Showing water jacket around carbureter, indicating a recovery of some of the waste heat

effect upon the general appearance as the radiator. The contour of the radiator is the same for the hood, and since the front end of a car is the most conspicuous, it naturally follows that it is prone to create the first impression. Fig. 9 shows the front of a Moore car, and while there are other and important features of a mechanical character to admire, even so, the radiator, as before stated, fixes the style.

Radiators are rather frail, and unless they are properly cradled they are likely to give trouble in service, due to the effect of road inequalities, first on the chassis frame, which ultimately induces torsional effects in the section of the radiator unless it is properly swung in view of the unstable nature of the platform. Fig. 8 adequately indicates the principle which is free from all such tendencies, and while there are several ways of carrying this principle into practice, the fact remains that the radiator should be free to respond to its individual inclination rather than to answer to the effect of road inequalities on the chassis frame.

Unless the water jacketing is carried well around valves much of the good that is expected from water cooling will be lost; in ports, for illustration, as shown in Fig. 12, the water should be carried all around them in order to afford an adequate measure of cooling. Fig. 12 illustrates a defective method, since the water jacket is stopped off on the upper side. Fig. 10 shows the spark-plug should be cared for in the same way. Flanges, if they are made of cast iron, will be frail, and heavy besides, whereas the drop-forged flanges, as shown in Fig. 11, are not only light, but they are strong and they present a good appearance as well. If the jackets are separate, as when copper jackets are shrunk over the cylinders on flanges, properly fashioned, it is important to make the joints so that they will not leak, as the result of vibration. Fig. 14 shows the method used on the Chadwick cars, in which a cylindrical copper jacket is fitted over a pair of cylinders, and the general appearance is rather good, while the manner in which the task is performed is such that the jackets remain tight in service.

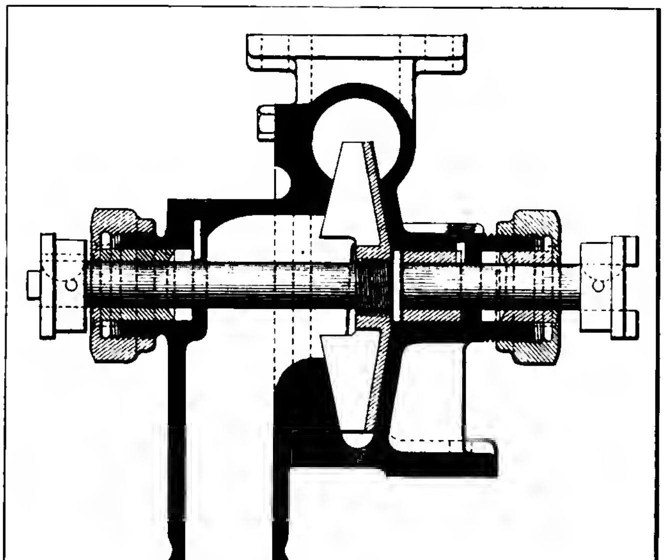

Fig. 15—Section of a centrifugal water pump, showing entrance of water at the side, around the shaft

Much Depends Upon the Ability of Air Propellers—If the fan is in the flywheel, it may be designed on a basis of a true screw, and the results will be very good provided the hood is tight and the motor is so thoroughly enclosed that all the air entering will have to pass through the radiator. This is a difficult condition to establish, and in practice it is generally safe to allow for a leak (around the radiator) of about one-third of all the air handled by the fan in the flywheel. Even with this allowance it is necessary to so design the hood and enclose the under side of the motor, that it will be quite as tight against air leaks as the best display of skill, on the part of the workmen, would seem to indicate. In some cases the vanes are placed on the periphery of the flywheel, and, as might be fairly expected, the amount of air handled will be on an increased basis, due to the greater peripheral velocity, attended, of course, by certain structural difficulties, such as a reduced diameter of the flywheel, hence a marked falling off of flywheel effect; clearance requires this modification, since, in general, considering the location of motors in chassis frames, flywheel diameters are somewhat restricted, even when fans are not placed on the periphery. If fans in or on the flywheel, are designed on a basis of air traveling at 30 feet per second, they will do very good service, and the number of blades to use will depend upon diameter, and the avoidance of over-lapping.

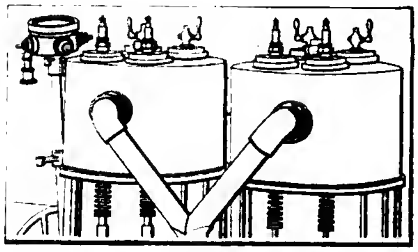

Fig. 14—Depicting a copper jacket over a pair of Chadwick cylinders, so fashioned that the connections come free

In general, it is the practice to use air propellers behind the radiator, even when the main fan is incorporated in the flywheel; this is a safety measure, taken, in view of the great difficulty involved in constructing a tight hood. When the flywheel is not brought to the aid of the air propeller back of the radiator, it is not to be supposed that the amount of air handled will be all that the occasion would indicate, for the reason that small air propellers are far from efficient, and to make up for this deficiency, it is necessary to employ a somewhat more commodious radiator to prevent radiator steaming.

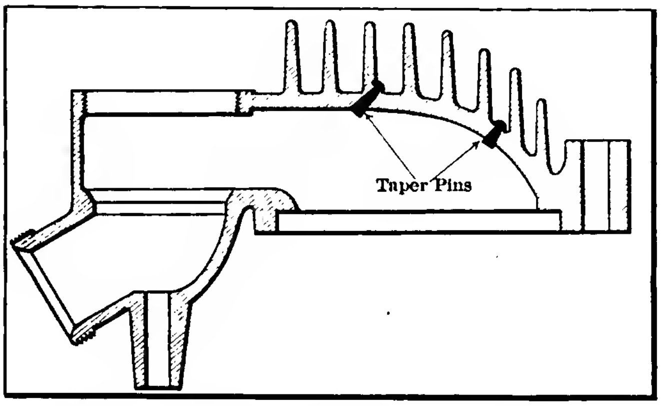
Hot Zones Abound in the Radiator—Unfortunately, due to the relatively small sweep of the fan-blades, when small air propellers are used behind the radiator, the effect is not uniform. If the radiator is approximately rectangular, covering an area of substantially 500 square inches of front (which is not far from the truth), even an 18-inch fan, which is about the largest size used, will only sweep about half of the front area of the radiator. It would seem to be a good idea to enclose the fan in such a way as to draw the air uniformly through all the tubes in the radiator, under the circumstances, but this practice has been avoided, owing to the difficulties involved, which are accentuated when the fan is belt driven. When the fan is in front of the motor, it projects an air current on to the front cylinder, which is of small account since the remaining cylinders are not given the same treatment. With the fan in the flywheel, the air is drawn by all cylinders and the effect is much more beneficial, since it is uniform in its effect on all cylinders.

Extracts from Vol. I, Part V, Chapter III, of a set of books, in preparation, by Thos. J. Fay, covering all phases of automobiling, from the point of view of designers, and in actual service.

INGENUITY IN THE MAKING OF REPAIRS

By Oliver Light

THERE is no trade or profession in which mechanical ingenuity is of greater utility or a more valuable asset to the fortunate possessor than in automobile repairing, where one is often called upon to make repairs quickly, which must be both practical and enduring. When failure of mechanism results through poor design or faulty assembling of cars or components at the factory, it is the repair man who must bear the brunt of the criticism, especially if he be agent for that particular make of machine. The owner can be pardoned for any lack of proper appreciation of difficulties which confront the mechanic, he realizing solely that the derangement will in most cases cause the loss of the services of the car, as well as involving considerable expenditure to make proper restoration.



Method of Saving Cylinder Head with Taper Pins

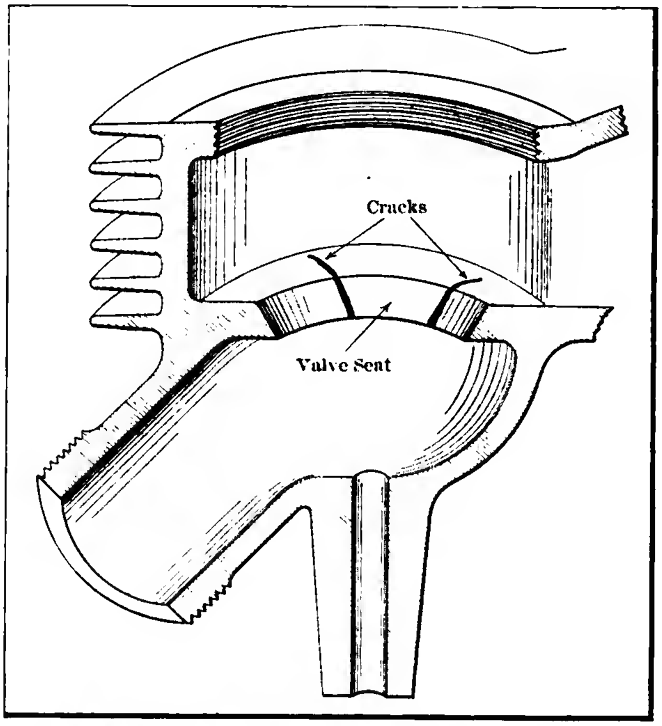
It must not be assumed that the writer means to imply that manufacturers of motor vehicles as a rule are negligent, or that poor workmanship and faulty design are often found in machines of standard make. Where any mechanism is produced in large quantities there will always be some machines that will not be as perfect as others, and with the demand which at present obtains for all classes of motor vehicles there is some excuse for failure to make careful inspection of the product before it is delivered. All motorists are not gifted with mechanical knowledge, their ranks being recruited largely from the business or professional classes, and it seems the irony of fate that the men best fitted by training and knowledge properly to appreciate and care for an automobile seldom possess one.

Then again, the larger proportion of the product is sold in territory more or less remote from the factory. Because of this the automobilist not proficient in mechanical work is dependent upon the factory representative for any attention that the machine may require, and in event of serious derangement the cost of repairs may be much greater than that of hundreds of miles of operation.

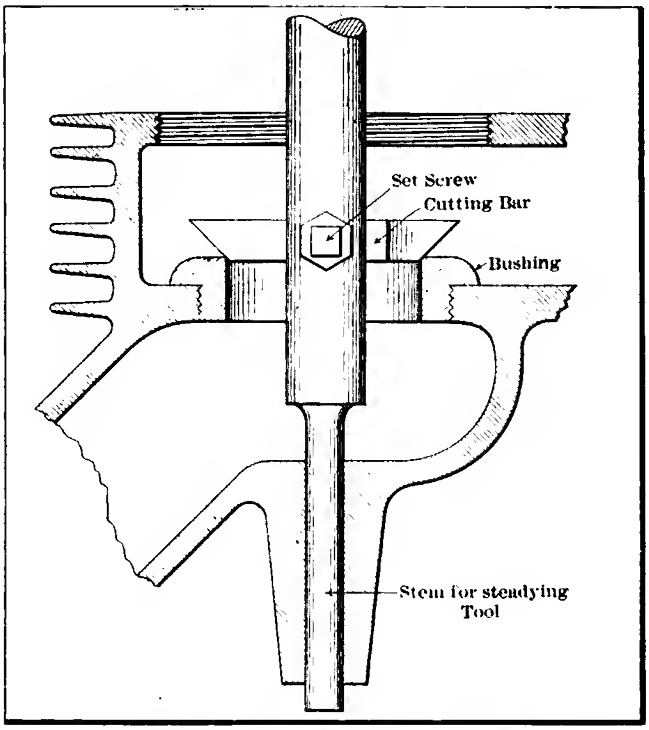
In event of serious derangement the ingenuity of the repairman may effect a substantial saving by repairs which will obviate the necessity of purchasing new parts. It is not that the components are always expensive, but there is necessarily more or less delay in obtaining spare parts from a distant factory. In many instances the parts may be restored to proper condition at small cost, not only eliminating delay, but also meaning a substantial reduction of expense, which is thoroughly appreciated by one of limited exchequer. As examples of what may be accomplished the writer will describe some repairs which were in every respect enduring and satisfactory, and although there is no great originality in the methods employed, the mode of restoration may interest, and perhaps be of some value to those who have to do with automobiles.

Saving a Flawed Cylinder Head—The owner of a machine of reputable make but old pattern was troubled with a mysterious loss of power and defective compression. After all points had been carefully examined and valves, cylinder head packing and piston rings found to be in good normal condition, the trouble was accidently discovered to be due to small blow or sand holes in the cylinder head which allowed a good portion of the gases to escape, especially when the head, of the cooled variety, became heated, the rise of temperature causing the metal to expand and the defects to become more evident and of more serious moment than when cool. The agent for the machine immediately advised the purchase of a new member, but as this was listed at $20, one can forgive the owner of the vehicle for his lack of interest in the suggestion.

The writer having been appealed to for advice suggested the removal of the defective combustion chamber for better examination. This was done and the blowholes discovered by inverting the head and filling with gasoline. One of these extended partly through a flange, while the other was between two of the cooling ribs. Facilities not being available for brazing or autogenous welding, the best method of repair which suggested itself was plugging the holes. A small eighth-inch drill was used to clean out the openings and to enlarge them sufficiently to run a small taper reamer through from the inside of the head. The outer end of the hole was slightly countersunk with a quarter-inch drill, and a standard taper pin of proper length and size was driven tightly into the hole. The portion projecting through the top of the head was riveted over,



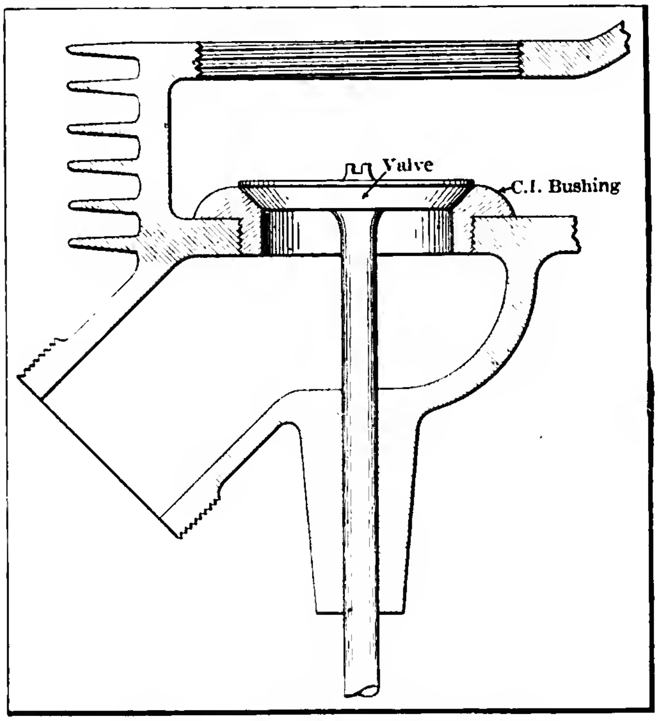
Cracked Valve Seat Eluded Detection for Long Time



Machining New Screwed-In Valve Seat

firmly securing the pin, and insuring an absolutely gas-tight joint. Obviously, every explosion tended to drive the pin more firmly into its seating, and the repair proved satisfactory in every respect. The writer has stopped blowholes by tapping out the enlarged hole and screwing in a small machine screw, but prefers the taper pins because they make a more sound job. The cost of this repair was $1.30, this including two hours' labor and the taper pins. This was just about one-fifteenth part of what a new head would have cost, not to mention the advantage of keeping the machine in commission.

Repairing a Cracked Valve Seat—On still another occasion a little bit of study enabled the writer to repair the cylinder of a motorcycle which at first sight appeared fit for the scrap heap. The trouble was manifested by loss of power, and upon test it was found that the compression, when the engine had become heated, was very poor, though appreciable resistance was offered if the engine was turned over while cold. Following a time-honored custom, the writer started to grind in the valves, and after a good seat had been obtained on the exhaust valve face, a test was made by daubing the seat with prussian blue to determine if the valve was bearing properly. Upon removal of the valve, inspection of the seat revealed the cause of the defective operation, namely, two good-sized cracks in the metal, as shown in the sketch. The valve chamber was integral with the cylinder, and perusal of the spare parts price list disclosed the fact that a new member would cost $15, while the factory was 1,000 miles away.



Showing How Valve Seated After Repairing

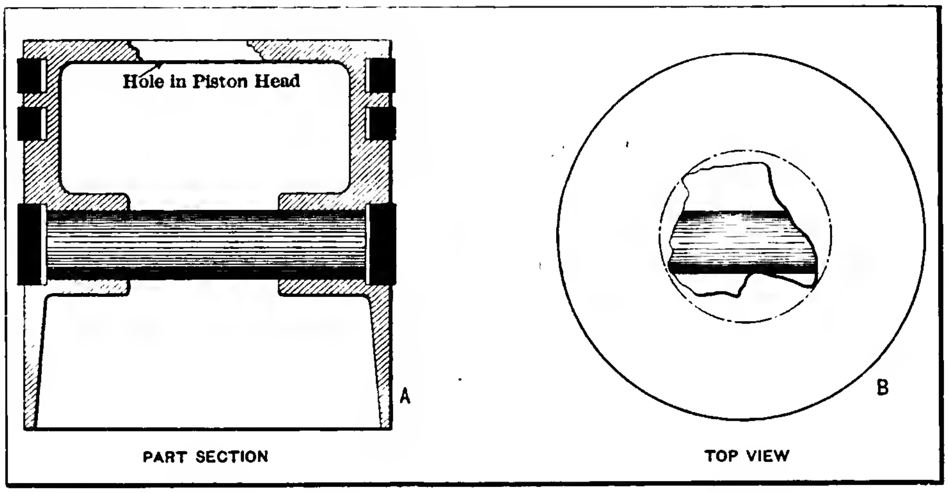
Upon the owner's responsibility, the writer undertook to make a repair, which was largely experimental, though later experience proved it practical. The cylinder was placed on the bed of a drill press, and firmly fastened in position. A special T boring tool, similar to the valve seat facing appliance shown (except that the cutter bar was adapted for boring), was placed in the chuck, and using the exhaust valve stem hole as a guide, the taper portion of the valve seat was turned away, leaving a straight hole a little larger than the over-all diameter of the valve head.

Once again the boring tool was brought into service, and this time, a piece of bar stock upon which a fine thread had been turned was used in place of the cutter bar. This piece was hardened, and placed in the holder, again using the exhaust valve guide as a steady rest for the lower portion of the tool; eight threads were cut into the 1-4-inch thickness of metal separating the combustion chamber from the exhaust port. An iron bushing was then turned up on the lathe to fit the threaded valve opening, and tightly screwed home, the bushing having been left large so that by heating the head it was shrunk in place. As further insurance against loosening, several small pins were driven into the wall of the cylinder seat to prevent the bushing from turning. The shoulder was of sufficient diameter to cover the edges of the cracks, with a small margin to spare.

By fitting a new cutting bar in the tool holder, the exact shape of the center section of the valve head, with the cutting edges at the proper angle for valve seating, it was not difficult to machine up the valve seating on the cast-iron bushing, and replace the valve. The effect of this repair was to raise the valve about one-eighth of an inch higher than the old position, which was easily compensated for by making a longer valve lift plunger, this being simply a three-inch piece of 3-8 cold rolled steel, case hardened. When the bushing was machined up the corner was rounded off as shown, as a sharp edge would doubtless have caused preignition of the charge when heated. This method of restoration was not costly, eight hours' labor at $4.80 and stock at 20 cents, bringing the charge to $5. As this time included making the special tool and the three cutter bars, it will be evident that the actual labor involved in putting in the bushing was very light. To make the cutting tool, a piece of seven-eighths cold rolled stock eight inches long was turned down for four inches to five-sixteenths diameter, this being the bore of the valve stem guide hole. A five-sixteenths hole was drilled through the large portion of the tool, and squared with a file. The stock of which the cutter bars were made was five-sixteenths square Novo steel, the tap being machined from a piece of tool steel bar the same dimensions, afterward hardened. A small 1-4-inch cupped point set screw held the cutter firmly in place in the holder after it had been accurately centered.

When an Overhead Valve Broke Loose—Another of the writer's friends was the owner of a well-known make of automobile the engine of which was fitted with overhead valves, and either through defective material or poor design it was a common thing for the valves to break, separating near the head, which fell directly in the cylinder. This meant one of two things in most cases: Either the top of the piston was punched through or daylight was admitted to the interior by the removal of a portion of the cylinder head, either of which entailed somewhat costly replacement. After several months of very satisfactory operation, one of the exhaust valve heads became severed from its stem, and, in common with those which had gone before, sought access to the outer air. Instead of making an opening through the cylinder head, as was customary, it broke through the top of the piston, leaving a jagged hole.

New pistons could be procured from the manufacturer, who must have done a thriving business in that line at the rate of $10 each. The writer was again consulted, and upon examination the piston was chucked in the lathe, the hole bored out perfectly round, and a fine thread cut therein. A steel plug with a large mushroom head was machined to fit and inserted. The cost of the repair, including the labor of removing and refitting the piston in the cylinder was $2.60.



Two Views of Hole Punched in Piston Top by Broken Valve

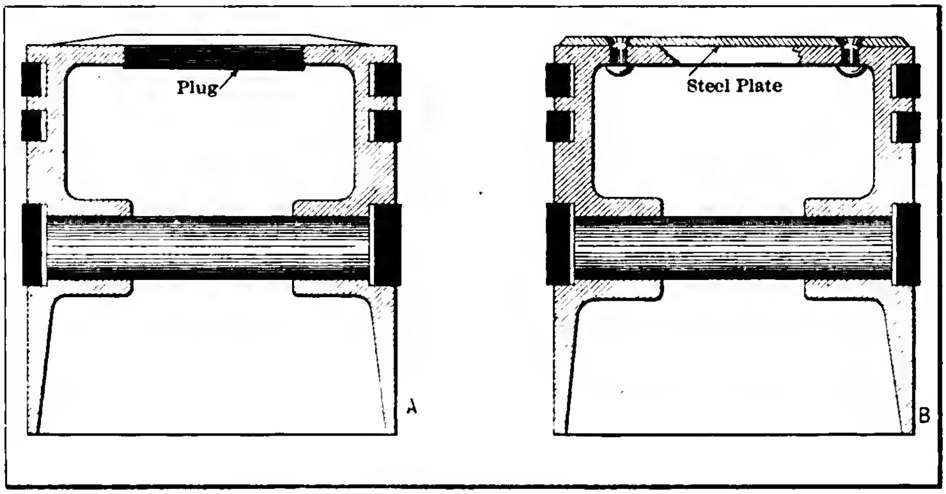
A similar break on another machine was repaired differently. A thin plate of steel one-eighth inch in thickness was cut out and riveted to the top of the piston, which had been surfaced off to receive it. The rivets, of which six were used, spaced equidistant from each other, were put in from the inside of the piston, and the ends upset in a suitable countersink in the steel plate, so that the top of the piston could be filed free of all roughness. The edges of the steel plate or disc were chamfered as shown, being cut with ample clearance to avoid scratching or cutting the cylinder walls. Very small machine screws could be used, these to be put in from the top, if desired.

Although this method of piston restoration has the effect of slightly increasing the compression, and perhaps increasing the piston weight, it is doubtful if the slight increase in length or mass will have any appreciable effect upon the practical running balance of the motor, if of the multiple cylinder form. In the cases which have come under the writer's observation, the addition of the plate or plug made absolutely no difference in engine balance. In fact, the weight of the plate would perhaps be no more than that of the piece of metal knocked from the piston. The advantage of the plate on top of the piston is that it can be applied without machining or boring out the hole, and if the top of the piston is true, there is no occasion for surfacing it. No one will question the strength of such repairs, as steel is several times the strength of cast iron, and for that reason a thin-walled piece will have the same strength as several times the thickness of cast iron.

It is often advisable to make repairs of this nature in preference to buying new parts, not only because of the substantial saving, but because the components which have been used together will have "run in" and be a proper fit. Putting a new piston in an old cylinder (unless it has been accurately machined to fit) gives no advantage, as the rings must find a bearing even if well machined. Then again, if a new cylinder is fitted, as would be thought necessary in event of a cracked valve seating, a new piston and set of rings would be required as well to insure a proper relation of components. Of course there are parts which can be obtained from the factory cheaper than the cost of repairing and before doing any patchwork, as described, the intelligent mechanic will always compare the expense of new parts, freight, express charges and delay, with his estimate on the job of restoration, and follow the course which will save his patron money. A repairer who observes this policy will be in business when his less liberal competitors are long out of the business and forgotten. The sketches presented herewith are not actual forms, being merely to show principle, as obviously it would not be fair to present illustrations which would be detrimental to the interests of the manufacturers whose product has been discussed so frankly.

MIXTURES OF HYDROCARBONS ARE BEST

Kerosene oil, while it can be and is used in motors, does not offer the advantages that follow the use of mixtures of hydrocarbons, such as do obtain in automobile gasoline, for the reason that the lighter and more volatile fractions in mixtures have a certain favorable influence on the heavy and less volatile product. When a light and a heavy fraction makes up the compound, the volatility of the heavy compound is hastened, and its rate of evaporation will be greater than would be the rate of evaporation of the same fraction in the absence of the light and more volatile fraction. True, the lighter of the two fractions will evaporate at the highest rate, and a residuum of the heavy fraction will have to be coped with. Even so, the situation takes on a practical phase, and it is because of this influence of the light on the heavier fractions, that makes it possible to consider a composite fuel, in which fractions can be included that would not burn alone.



Different Ways of Repairing Broken Piston with Plate

LETTERS INTERESTING

DON'T LIKE GRINDING

Editor THE AUTOMOBILE:

[1,988]—Being constant readers of "The Automobile," we were anxiously waiting to see what Mr. Fay would tell us concerning the best method of finishing motor cylinders, which sums up to be grinding, but we here would like to have a few questions answered: Isn't it true that a grinder wheel will wear down to a less diameter from the beginning of the cut to the end, and since it is fed in parallel, will it not leave a cylinder slightly conical? Not to mention the fact that the wheel must necessarily be small, hence will wear fast, and a slight irregularity must be allowed for play of its spindle. We believe a cylinder, if reamed for the finishing cut and then polished with emery cloth on a wooden drum, would make a superior finish, arguing that a reamer will make all cylinders the same size and a slight use of the emery cloth will make a finer finish in the cylinder than a grinder. We would be pleased to hear from some who have used reamers for this purpose.

Denver, Col. PETERSON BROTHERS.

Yes, a grinder wheel will wear down to a less diameter at the end of a long cut, just the same as a reamer will. The writer is familiar with the practice in one automobile shop in particular where the old-fashioned method of which you speak is still in vogue. There, when the reamer wears down below size, it is sent to the tool room and the inserted blades are reset and then reground. In doing this, it is left five-thousandths above size so as to provide in part for future wear. This is used until it wears down to about four-thousandths of an inch below size, which is at the end of about ten reaming operations. That is, in reaming out ten cylinders the reamer wears from five-thousandths large down to four-thousandths small, a total of nine-thousandths wear. This occurs in machining ten cylinders, and the wear may be assumed to be fairly equal and even. In that case the cylinders may be assumed to be about as follows:

Number 1 cylinder, large .005".
Number 2 cylinder, large .004".
Number 3 cylinder, large .003".
Number 4 cylinder, large .002".
Number 5 cylinder, large .001".
Number 6 cylinder, just exactly to size.
Number 7 cylinder, small .001".
Number 8 cylinder, small .002".
Number 9 cylinder, small .003".
Number 10 cylinder, small .004", after which the reamer is trued up and the process started over again.

The above shows about what may be expected from the reaming process, although it doubtless represents extreme practice. In any case, it is fair to assume that by this process not more than half of the number of cylinders are correct to size (above there is but one correct in ten, a percentage of just .10).

In the matter of wear doubtless you have forgotten that emery is harder than steel, the former ranking between 9 and 10 in the scale of hardness, while the steel comes in at about 7. If this were not true it would not be possible to use emery to grind tools of the finest and hardest steel. Since it is true, would it not also be true that the softer of the two (this being the steel), doing practically identical work, would wear more?

Your argument would be very good if it were not founded upon the statement, "a reamer will make all cylinders the same size," which is not true to actual conditions. You will find upon examination that the majority of automobile builders use the grinding process in finishing the cylinders, although its use doubtless requires more skill than does the reamer.

To take up your last statement, if you use emery cloth to give the cylinder a fine finish, why not use an emery wheel (which is what all grinder wheels are) directly and save the work of reaming, obtaining your fine finish equally as well in one case as in the other?

ON HOT ENGINES

Editor THE AUTOMOBILE:

[1,989]—As you know, I have always advocated hot engines. I therefore wish to add a few words to your answer to Mr. Mannheim on page 278 August 12 issue. The Edge tests there given show nothing except the results from his particular engine. Many engines are so badly designed that they get hot in spots. They warp badly, or they do not oil properly. Or the oil used will not stand high heat, and so fails to lubricate. Any of these things would reduce power, and the Edge tests simply show that his engine was not properly designed for high temperature. The high efficiency of air-cooled engines, as shown on more than one efficiency contest, proves without the chance of question the value of temperatures much higher than water-cooled engines reach.

There are two decided advantages in particular to be found in a hot engine. At high speed, it heats the charge thoroughly so it ignites easier and is sure to burn more fully. At low speed, it does not get cooled down by the walls and so the pressure holds up to the end of the stroke much better, making the engine pull more like a steam engine. There are less misfires, less odor, greater economy of fuel and better results generally. After throwing off the spark the properly-hot engine will sometimes fire a charge in three or four, but this does no harm. So long as it is not hot enough to lose power on hard pulls it is not too hot.

Say to Mr. Sargeant that a little graphite will cure his clutch. This will not burn out like oil and stops the fierceness. If the spring is so weak that the graphite causes it to slip, then use a less slippery powder, like chalk, or fuller's earth. The presence of a powder seems to render the gripping gradual and more sweet than the clean leather.

Reading, Pa. CHARLES E. DURYEA.

Exception must be taken to some of the remarks on hot engines. It is hard to see how the walls of the cylinder, whether hot or cold, can influence the pressure at the end of the pressure stroke to a measurable extent, since exhausting always commences with a pressure of not less than 40 to 50 pounds per square inch. It is doubtful if it would be possible to get the cylinder walls so cold as to reduce this and even if it were, this would be an advantage, because lower temperature means lower pressure, and this is a time in the cycle when low pressure is desired; in fact, several prominent air-cooled engines desire it so badly that they add an extra valve with its additional complications for the express purpose of reducing it in a hurry and as much as possible.

CAUSE OF OVERHEATING

Editor THE AUTOMOBILE:

[1,990]—Will you please give me through "Letters Interesting and Instructive" all the possible causes that you think of, which might occasion the following trouble with a 35-horsepower five-passenger car, make-and-break ignition, Bosch magneto.

Going up a long, steep hill about 400 feet climb in a mile and a half (road perfect) about half way up the motor gets hot, the water steams and boils out of overflow pipe, motor slows down, misses, and there are explosions either in exhaust pipe or possibly back-firing in carbureter. The engine finally stops. There is no back-firing, however, upon starting it again, but it takes considerable cranking to get it to start.

Outside of this particular hill the car runs well, and has made runs in stretches of fifty miles without stops, on hot days, through hilly country (Pittsfield to Manchester) without any trouble.

Car is new and has been run about 1,500 miles. Panhard medium oil has been used. Each time I attempted to take the hill on the high gear. I have three speeds.

New York City. SUBSCRIBER.

Since you are using a good grade of oil, and using it freely, your trouble must be one of two things: either your spark is too early or there is something the matter with the water-circulating system. The first is just a possibility, whereas the latter is doubtless your real trouble. Look to the pump first and make sure that it is running all of the time. Yours may be one of the cars built with a weak point in the water-pump-driving system, which is intended to shear when an obstruction enters, thus saving the more expensive pump parts. This cotter or taper pin may have sheared without your knowing it. Running slowly, this would not be noticed, as with liberal water passages the engine would run thermo siphon. But when the engine is made to work hard the difference is noticed and, as you describe it, "the water steams and boils out of the overflow pipe." It may be that there is a screen somewhere in the water system which has become clogged up so that very little water passes through it. At slow speeds, again, this would have little effect, but when hills are climbed the engine needs more water, and the lack of it is seen.

It is just barely possible that the pump is too small for the engine to which it is fitted, and does not throw enough water to cool it satisfactorily. By connecting the pump to a source of water and pumping into a large tub, measuring the output for some unit of time, you can readily determine this. An automobile engine should have very nearly, for a rough-and-ready rule, a gallon of water per horsepower per minute, which in your case would work out to 35 gallons per minute.

If you don't fix this trouble at once, some time when you are attempting a steep hill on the high gear, your engine will get so hot as to seize, and then will be in for an overhauling and you, for a nice, large bill.

ANSWERED AND DISCUSSED

DIFFERING VALVE LIFTS

Editor THE AUTOMOBILE:

[1,991]—Will you kindly explain the following point in your "Letters Interesting and Instructive." My car has mechanically operated valves, all on one side, with adjustable lifts. These lifts are set with varying amounts of play, so that some lifts raise the valves from their seats almost at once (as soon as the lifts have risen, say, 1-32 inch or less), while others have 1-8 inch or more play. This condition produces a noisy valve action, although the lifts are fitted with spring-controlled buffers. The foreman at the maker's local branch says that this uneven setting of the lifts is necessary for the proper timing of the valves, so that each inlet, say, will open at the proper point in the stroke; and that if he "takes the slap out," the valves will be wrongly timed. Now does not this indicate that the cams are not accurately set? For, with a perfectly accurate camshaft, would not the same setting on all lifts—say 1-32 inch or 1-64 inch play—produce a correct valve action?

Your answer will oblige an interested subscriber. Daily papers are neglected when "The Automobile" arrives each week.

New York City. L. I. W.

If there are more than two settings, one for the exhaust valves and one for the inlets, the repair man was either making fun of you to cover his own lack of knowledge or else the manufacturer does not know very much about building engines. This is self-evident, from the bare statement that what is the right valve setting in one of four cylinders of any given engine is also right for the other three, and no amount of reasoning could make it different. So, if the valves and other parts of the valve-operating system are correctly machined, the proper clearance for number one cylinder valve lifter is also the proper clearance for numbers two, three and four valve lifters, whether this be 1/64, 1/32 or even 1/16 inch, of which more later.

Taking up the other side of the above, if the clearances must be different because the valve-operating parts are not correctly machined, we would advise you to sell the car and get a good one.

You are right about the correctly-machined camshaft. This should be such as to, in correlation with the other parts, call for equal setting for all lifts. Now, as to correct amount of clearance, this should be just as small as is possible and the smallest amount spoken of above, namely, 1/64 of an inch, would be about right for the average motor.

One additional possibility is this: In the past year or so the best or standard practice in valve settings has changed. Now, it is possible that your engine was built several years ago, and that the repair man is trying to give you an up-to-date valve setting with the old camshaft. If this is the case (and even in this the amount of clearance would be the same for all inlets and the same, but different from the inlet, for all exhaust valves; that is, there would be but two settings) have him stop it, as the best way to attain the up-to-date result is to buy from the manufacturer a camshaft of late date and install it in the engine. This would give the desired result without unnecessary noise, due to too much clearance.

FUEL ECONOMY AND HEATING

Editor THE AUTOMOBILE:

[1,992]—Will you please help me out in a little trouble that I am having, this being one of the few cases in which I have been obliged to seek outside aid. For several years I drove an air-cooled car of a popular make, having one of its largest type of four-cylinder engines. This season I bought a car of the same type from the same concern. With the old car I always got the best results from the engine when the gasoline supply was cut down at the needle valve to almost the extreme limit. This, also, as a matter of course, gave me the greatest fuel mileage. With the new car I find that when the valve is closed beyond a certain point, the engine overheats and looses power for hills and hard work, although when thus cut down it will run at a saving of fully one-third of the fuel. While the car will run all day at the hardest kind of work without a sign of overheating when the needle valve is properly adjusted for this result, it will badly overheat within a few miles if the supply is cut down much below this point. All of my former experience has taught me that an engine will work cooler with a thin carbureter mixture. I should be pleased if you would inform me through the department of "Letters Interesting and Instructive" in your journal as to the cause of this and as to whether an adjustment can be made to save overheating when the gasoline supply is cut down to its low economy limit. E. M. MURRAY.

Chicago.

There are two possible sources of the trouble in your case, both worth looking into. It is possible that you are using too late a spark, although the very good fuel mileage record would seem to preclude this. Then, it may be that the exhaust cams on this new car have slipped around so that the exhaust is opening too late. When the mixture is rich you get the required power at slow speeds. In that case, that is, with the engine running slowly, the effect of this is not very noticeable. When the fuel is cut down the thin mixture makes it necessary to run the engine faster to obtain the same power.

If there was a small leak in your fuel-supply system it might have the result you describe. Thus, if there was a pin hole in the inlet manifold casting the loss from a rich mixture would be a very small proportion of the total and would have no noticeable effect on the result. On the other hand, the loss from a very thin, poor mixture would form a large proportion of the total result and would affect the running of the engine so as to cause the overheating.

If, upon examination, you fail to find the trouble, it would be well to communicate with the manufacturers of the car, who, priding themselves upon fuel economy, would go to some trouble to set you right.

CYLINDER PATTERN-MAKING

Editor THE AUTOMOBILE:

[1,993]—I am thinking of building an automobile engine and want to inquire where I can get some knowledge of pattern-making and other information regarding such work. Is there any paper published regarding such matters? If so, would you please inform me of the name of the same. Or, in your judgment, where would it be best to seek such knowledge? I am an interested reader of "The Automobile" and find it a source of constant information. I think that I will try a two-cycle engine first, as that seems to be simpler than the four-cycle form.

Boston. EDWARD W. CARTER.

It is doubtful if pattern-making can be learned from books or other reading matters, for one reason, because very few pattern-makers are able to put their knowledge into words, and thus very little on this interesting subject finds its way into print. If you really want to learn pattern-making, the very best way will be to go into a foundry for about two years, moving around so as to get an opportunity to learn all parts of the trade. Then go into a pattern-making shop, and you will find that the two years spent in the foundry are just as much good to you as the same time spent in the pattern work would have been, or more so.

Many articles have been published in THE AUTOMOBILE lately on this subject. Possibly you have missed some of them. For fear that you have, we are appending a list of them as follows:

July 1 issue, pages 11 and 12.
July 8 issue, pages 53, 54, 55 and 56.
July 15 issue, pages 97, 98, 99 and 100.
July 22 issue, pages 137 and 138.

An excellent work on this subject, just published, may be obtained from the Class Journal Company, 231 West Thirty-ninth street, New York City. This is entitled "Practical Pattern-Making," by F. W. Barrows, and the price is $2. An old but good book on the same subject contains much of merit. This is "Pattern-Making," by Joshua Rose, and the price is about $2.50. If you are interested in books, "Modern Moulding and Pattern-Making," by J. P. Mullin, at $2.50, ought to be worth having, as ought also, "Foundry Practice," by H. M. Ramp ($3), and "Toothed Gearing," by A. Foreman Pattern-maker, the price of which is $2.25.

These trade journals are published which touch directly on the subject, as well as a number of others not mentioned, which touch on it indirectly: *Wood Workers' Review*, Chicago, monthly; *Wood Worker*, Indianapolis, Ind., monthly; *Wood Craft*, Cleveland, monthly; *Foundry*, Cleveland, monthly; *Castings*, Cleveland, monthly.

All of the others are directly interested in the wood and lumber trade, and so only touch upon pattern-making as a specific subject in an indirect way.

They would thus be of less use to you in your desire to learn pattern-making than would another journal devoted directly to this and allied subjects.

The best method and one that will give the most satisfactory results, if you are in earnest, is to go directly into the shop.

MORE ABOUT SKIDDING

Editor THE AUTOMOBILE:

[1,994]—In "Letters Interesting and Instructive" in the August 5 issue of "The Automobile" I read with much interest the letter on skidding and your remarks on same. You say that by turning the steering wheel in the same direction as the road wheels are slipping the skidding will be increased by reducing the resistance at front wheels. Now you seem to forget that while the car is skidding the rear wheels are still propelling the vehicle forward, and that when the front wheels are turned in the same direction as the car is slipping the tendency of the rear wheels is to straighten out with the front wheels, thus overcoming the tendency to skid in nine cases out of ten.

For example, say the car is skidding to the right, the front wheels are in the position they were before the car began to skid. The car is now attempting to describe a circle, the front part of the car going to the left, the rear part to the right; now when the wheels are turned in the same direction as the skid (to the right) the car naturally begins a circle in the opposite direction, the front part of the car going to the right, the rear wheels being thrown to the left; the front wheels are immediately straightened out and the skidding is temporarily overcome. Every experienced driver will tell you that this is the only way to keep a skidding car under control. I do not agree with Mr. Mayer about increasing speed when skidding. I find that by cutting off the current with clutch in and making the car turn the engine over, will in many cases prevent the car from skidding and gradually slow up, where an application of brakes would immediately produce sideslipping.

I notice that Mr. Chelf is having trouble with his Remy magneto, which he describes in letter No. 1,964. This trouble is altogether due to improper adjustment of contact screw of timer. When motor misses at slow speed, as his does, this rubber-covered screw should be turned to the left. Several adjustments should be tried and when he gets it right he will find that his engine will run better on the magneto than on the batteries at all speeds. The screw which holds the timer cover on should be loosened in order that the adjusting screw may be turned; when the proper adjustment is found, it should be again tightened. I. B. G.

Nashville, Tenn.

It is certainly news that when the car is misbehaving, so to speak, this action will be corrected by making it easier. That is, when the car is slipping to turn the wheels as you indicate removes the only obstacle to this slipping action. It is hard to see how this will act as a preventative; in fact, the more thought given to it, the more it seems as if this will increase the slipping action, by, as was said before, removing the only existing obstacle. In the appended figure, an attempt is made to explain this as the writer sees it and as he believes is right. Let A B C be the normal center line of the car proceeding along the street. Then let B D represent the center line of the car when skidding, the radius B E showing how the rear wheels rotate around the front ones as a pivot. In this position, the slight angle which the center line makes with the line of the front wheels, indicated by the angle and which increases with any increase in the slipping action, acts to prevent skidding. Although the action may be feeble, it is on the increase, and may ultimately become large enough to stop the slip entirely and solely of itself, as perhaps the hypothetical case indicated by the third position, F B G would seem to indicate.

If now, the wheels are turned to the right, as shown in the second part of the figure, which represents the same case but with front wheels turned so as to make a right angle with the new or skidding center line. In this case, the obstruction or drag on the movement offered previously by the front wheels is absent, and the wheels, in fact, the whole car, is perfectly free to continue its rotation so long as any impulse to do so remains. Not only is this drag removed, but by turning the front wheels in a direction which frees them, they are liable to start in and participate in the movement by rolling in the general direction of the skid, which then becomes a tangent to the former direction of motion, instead of the circular movement.

If, instead of turning the front wheels in the direction of the slip, they are turned in the other direction, the angle of resistance to the motion, and with it, the resistance itself, is materially increased, as shown by the larger angle B. In this latter case, the motion tangent to the first movement is impossible, since not only the rear wheels but the front ones as well must be bodily dragged sideways, as indicated by the two arrows. The more thought one gives to this question, the more one is convinced of the correctness of the above.

Thus far, the reverse action of the front wheels, rolling to the left for a rear wheel skid to the right, has not been considered, but a moment's thought will convince that this would, like the rear wheel action, only be increased by turning the front wheels at right angles to the skidding direction.

This is self-evident if it is considered that with the wheels left pointing forward, they must, to roll to the left, scrape across the pavement, this action being directly against the side of the tires, and being also such as to pull the tire off of the rim. Now, we know that the latter accident does not happen.

By turning the wheels in the direction of the sliding, even this resistance on the part of the front wheels is eliminated, and they are free to pursue any tendency to roll around to the left. The result of this would be to spin the car around its midpoint, like a top, the front wheels turning to the left and the rears to the right.

Our thanks are due to I B G for his solution of the Remy magneto trouble, and the attention of Mr. Chelf, the writer of letter number 1,964, is directed to this way out of his trouble.

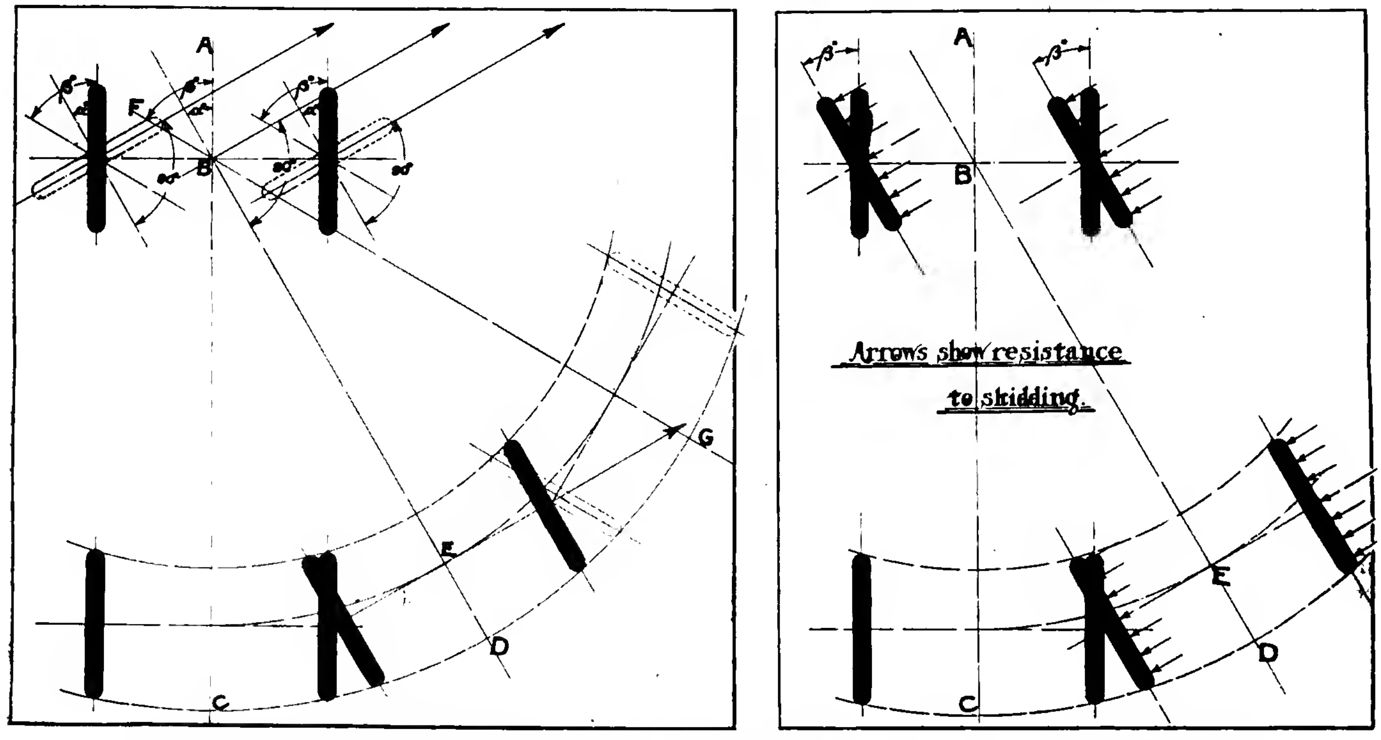


Diagram of Happenings When the Car Skids and (at the Right) the Proper Way to Turn the Wheels to Avoid It

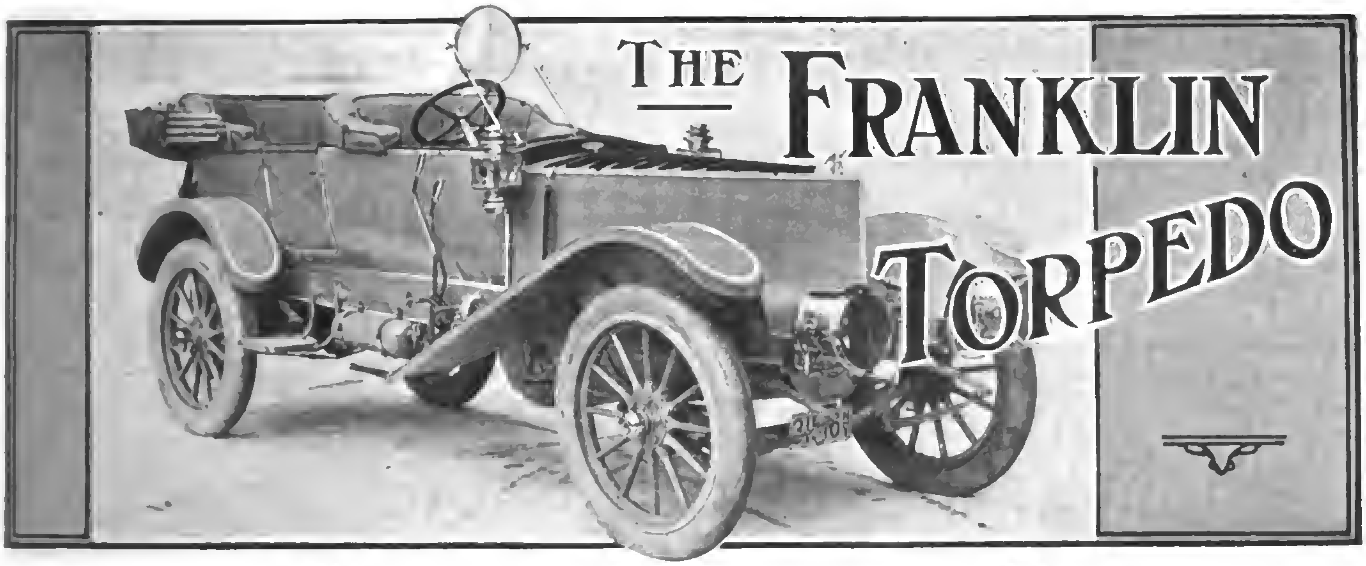
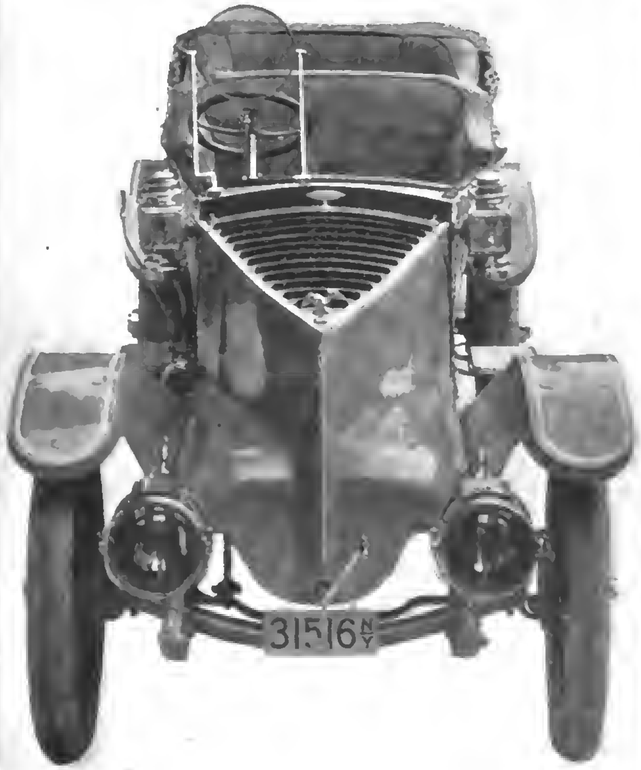
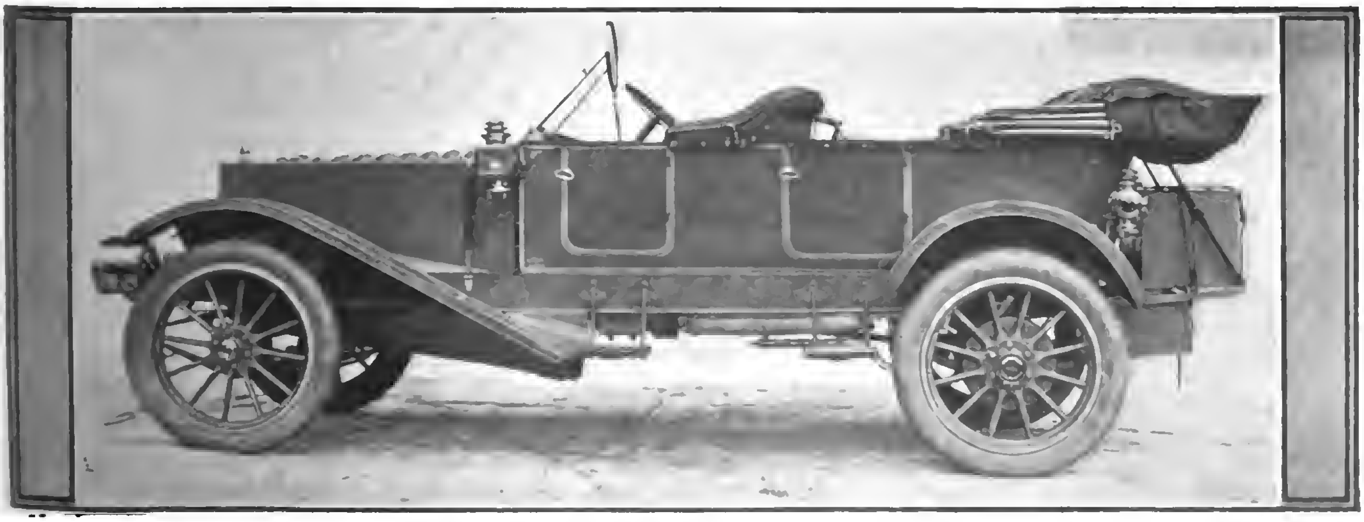
THE FRANKLIN TORPEDO

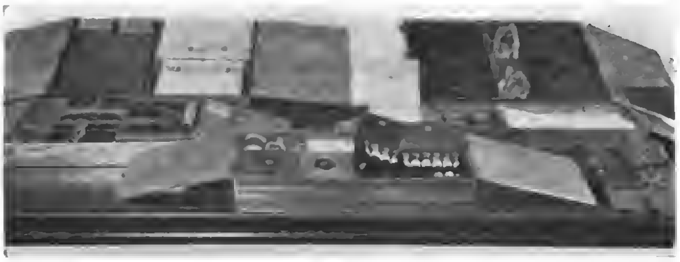


FIRST among the American adaptations of the "torpedo" body designs so popular in England is a special six-cylinder Franklin just completed by the Syracuse, N. Y. factory, for the personal use of H. H. Franklin. This Franklin "torpedo" shows several radical departures from its European models, and in one respect at least, markedly improves on them. The European practice, as has been frequently illustrated in these columns, is to confine the characteristic torpedo effect to the body proper, leaving the hood in its original square shape. The Franklin, however, extends the torpedo idea to its logical conclusion, and makes the hood pointed, like the prow of a boat. This at once brings the whole of the car into harmony; in fact, the hood now gives the keynote of the whole design. The rest of the body continues the boat-shaped lines in a graceful curve to the rear, swinging upward around the tonneau seat. The doors, of course, are full height, both front and rear, two for entrance into the tonneau, and one, on the left side, for the front seat. Thus an unbroken line, emphasized by a molding, sweeps around the car like the gunwale of a boat.



This Franklin body is built on the regular six-cylinder 42-horsepower chassis of the 1910 model. The car has a special bevel gear ratio which enables it to attain a speed of from sixty to seventy-five miles an hour. The novel design of the hood is made possible by the 1910 Franklin air-cooling system, which eliminates the fan formerly





Some Things the Franklin Torpedo Locker Contains

necessary. Admission for the cooling current is provided by louvres in the top of the hood. The body is of aluminum, finished in battleship gray striped with pearl; instead of the usual high polish it is given a simple rubbed surface, very businesslike in appearance. Mr. Franklin's monogram appears on the doors. The seats are low and deep, with ample leg-room, and are upholstered in chocolate-brown goat-skin. The same material is used for the rest of the interior. The folding top, instead of the regular black, is in a rich dark blue. The windshield is of a type never before seen on a touring car, though often used in Europe on racers. It is designed to afford protection to the driver only. The glass is circular, about a foot in diameter, and is held on an adjustable standard, close in front of the driver's face. All exposed metal work has a nickel finish.

The equipment of the car is unusually complete. It includes an electric speedometer light and small electric auxiliaries to the oil side and tail lamps. The rear construction provides lockers and drawers for stationery, toilet articles, a first-aid-to-the-injured outfit, caps, goggles, gloves and maps. The name "Franklin Torpedo" is displayed on a silver plate on the Circassian walnut dashboard, where it extends above the hood, and the extreme "prow" is surmounted by a small silver eagle.

Not by reason of its unusual body construction alone is the Franklin "Torpedo" of interest, but also as an example of the growing tendency among men of means to give their cars an individuality lacking in the ordinary factory product. When a man has his yacht built to order and christened with a distinctive name, he does not wish to have his automobile, sometimes representing an equally great investment, resemble other men's cars, like peas in a pod. This tendency in turn reveals another, namely, that the automobile is not now regarded as the plaything of a single season, to be used a few months and then cast aside for a newer, but rather as the companion of many tours, whose usefulness will endure for many years of pleasurable and economical driving.
